1. Species are grouped according to the maximum-likelihood tree in Figure 339.

2. Without symbols: list of type strains of *Streptomyces*; † list of type strains of *Streptacidiphilus*; * list of type strains of *Kitasatospora*.

3. Groups as described by Williams et al. (1983a), grouping on the basis of numerical identification.

4. Groups as described by Williams et al. (1989), grouping mainly on the basis of numerical identification according to Williams et al. (1983a).

5. Groups as described by Kämpfer et al. (1991), grouping on the basis of numerical identification.

6. Groups as described by Hatano et al. (2003), grouping on the basis of phenotypes, DNA–DNA hybridization and sequences of *gyrB*.

7. Groups as described by Lanoot et al. (2002), grouping on the basis of protein profiles.

8. Groups as described by Fulton et al. (1995), grouping on the basis of fingerprints of the rRNA operon.

9. Groups as described by Ochi (1995), grouping on the basis of the ribosomal AT-L30 protein.

10. Groups as described by Kataoka et al. (1997), grouping on the basis of partial 16S rRNA gene sequences containing a variable α region.

11. Groups as described by: Labeda and Lyons (1991b), L1; Labeda and Lyons (1991a), L2; Labeda (1998), L3; Labeda (1996), L4; Labeda (1993), L5 (grouping on the basis of DNA relatedness).

12. Groups as described by P. Schumann (unpublished), grouping on the basis of ribotyping.

13. Groups as described by Lanoot et al. (2004), grouping on the basis of Box-PCR.

14. Groups as described by Lanoot et al. (2002), grouping on the basis of protein profiles.

15. Groups as described by Lanoot (2004), grouping on the basis of DNA–DNA hybridization.

16. Groups as described by Lanoot (2004), grouping on the basis of DNA–DNA hybridization.

17. Groups as described by Lanoot (2004), grouping on the basis of ARDRA.

18. Groups as described by Lanoot (2004), grouping on the basis of ARDRA.

19. Groups as described by Lanoot (2004), grouping on the basis of analysis of the ITS region.

20. Groups as described by Lanoot (2004), grouping on the basis of 16S rRNA-ITS RFLP.

21. Groups as described by Guo et al. (2008), grouping on the basis of multilocus phylogeny calculated with the sequences of five housekeeping genes (*atpD, gyrB, recA, rpoB, trpB*) and the 16S rRNA gene.

22. +, Strains that were used in the study of Guo et al. (2008) but did not belong to one of the four detected groups; yes, strains that show the same grouping (I–IV) as in the 16S rRNA gene sequence tree; no, strains do not show the same grouping (I–IV) as in the 16S rRNA gene sequence tree.

23. Groups as described by Kim et al. (2004), grouping on the basis of *rpoB* gene sequences; +, strains that were used in this study; Group A16, group A18, group A1B, group F, *Kitasatospora* and Asn(AAC), names of species groups based on the *rpoB* gene according to Kim et al. (2004).

24. Morphological characters of species described before 1974 according to Pridham and Tresner (1974a, 1974b) and Baldacci and Locci (1974). n, Not determined.

I. Spore color en masse indicated as W (White), Gy (Gray), Y (Yellow), R (Red), B (Blue), G (Green), V (Violet), Bl (Black), Ba (substrate mycelium pink-red to orange-red, aerial mycelium pink, gray-pink, and violet-pink), Bi (substrate mycelium colorless, reddish and orange, yellow to brick red, aerial mycelium pinkish white), Hi (substrate mycelium brick red, aerial mycelium beige to pink-beige), Sa (substrate mycelium brick-red to orange, aerial mycelium white with pink and yellow shades), Lu (substrate mycelium yellow, yellowish to brown, aerial mycelium light yellow, yellowish to beige), Gr (substrate mycelium brownish yellow, aerial mycelium pinkish beige with lilac shades), Ci (substrate mycelium yellow to greenish, yellow and brown-yellow, aerial mycelium pinkish with beige and lilac shades), Ar (substrate mycelium light yellow to yellowish to pinkish yellow, aerial mycelium basically white with yellow, pink and gray), Ke (substrate mycelium yellow, yellowish to hazel-nut yellow, aerial mycelium beige

Fingerprinting techniques.

Randomly amplified polymorphic DNA (RAPD) PCR. In RAPD-PCR, single primers with arbitrary nucleotide sequences are used to amplify DNA at low annealing temperatures in order to detect polymorphisms. The method is used as a rapid screening method to detect similarities among streptomycetes. For meaningful results, a stringent standardization of reaction parameters is required; the latter include primer sequence, annealing temperature, buffer components, and concentration and quality of template DNA. RAPD-PCR results in a characteristic fingerprint of PCR products. The standardized procedure allows the detection of chromosomal differences between individual isolates without having any prior knowledge of chromosomal sequences.

Mehling et al. (1995) used this technique in a study of actinomycete species, but did not detect any characteristic banding patterns for closely related species unless they used a highly specific actinomycete primer. Even so, the resulting fingerprints contained only four bands. Similar results were reported by Huddleston et al. (1995), who used the method to try and determine interspecific relationships among members of the *Streptomyces albidoflavus* cluster of Williams et al. (1983a). Anzai et al. (1994) investigated 11 primers with various fragment patterns from zero to 20 and found that variations in fingerprint patterns can be obtained by substitution of a single base on the arbitrary primer; the most significant differences were observed when the sequence at the 3′ end was altered. Anzai and colleagues used an optimized procedure to study the relationship of *Streptomyces virginiae* and *Streptomyces lavendulae* strains; members of these taxa were assigned to the same numerically defined clusters by Williams et al. (1983a) and Kämpfer et al. (1991). Good correlation was found between the RAPD-PCR data and corresponding DNA–DNA hybridization, low-frequency restriction fragment analysis, and cultural and physiological tests, though the interspecific relationship of *Streptomyces lavendulae* and *Streptomyces virginiae* strains was not clarified.

Restriction digests of total chromosomal DNA. Low-frequency restriction fragment analysis is based on the digestion of the entire bacterial chromosome with restriction endonucleases that cut infrequently. Rare AT cutters are used for streptomycetes given their high DNA G+C content. PFGE is used to separate the resultant fragments. In the first study, Beyazova and Lechevalier (1993) examined 59 strains from eight species-groups and found that the method was useful as related strains clustered together. However, some discrepancies were found, for example, for strains grouped into the *Streptomyces cyaneus* cluster of Williams et al. (1983a). Like RAPD-PCR, the method seems to be useful for the detection of very closely related strains, but cannot be used to resolve interspecific relationships. A misinterpretation of banding patterns can result from large chromosomal amplifications or deletions (Rauland et al., 1995).

Nucleic acid sequence comparisons of 16S rRNA and other genes. In an early review of the application of 16S rRNA gene sequence analysis to the classification of streptomycetes, Stackebrandt et al. (1992) highlighted the importance of the region selected for comparison. They found that relationships between strains were influenced by which variable region (*a*, *b*, or *c*) was studied. Kataoka et al. (1997) were able to resolve inter- and intraspecies relationships between 89 streptomycete type strains, representing several clusters of Williams et al. (1983a) by sequencing the *c* region. Forty-two of the strains were found to have unique sequences; the remaining strains were assigned to 15 groups. In a more extensive study, Kataoka and his colleagues (1997) deposited the sequences of the *c* region of 485 *Streptomyces* strains in GenBank. At present, this is the largest publicly available set of streptomycete 16S rRNA gene sequence data.

A phylogenetic tree based on comparison of the *c* regions of representatives of the major cluster-groups defined by Williams et al. (1983a) was published by Anderson and Wellington (2001). They were able to confirm the taxonomic status of the phenotypic groups, apart from the *Streptomyces olivaceoviridis* and *Streptomyces griseoruber* strains which had identical *c* regions; these strains were found in clusters 20 and 21 of Williams et al. (1983a), respectively, but formed cluster 9 in the study of Kämpfer et al. (1991). The sequence data also showed that the 60 strains assigned to three species-groups in the *Streptomyces albidoflavus* group (Williams et al., 1983a) could be divided into six groups (Kataoka et al., 1997); the three phenotypic subgroups of Williams et al. (1983a) were maintained, but did not cluster together.

Hain et al. (1997) designed 16S rRNA oligonucleotide probes to determine intraspecific relationships within the *Streptomyces albidoflavus* group and found that the resultant sequences were useful for species delineation, but not for strain differentiation. The intergenic 16S–23S rRNA spacer regions were found to be more suitable for the delineation of intraspecific relationships within that cluster. Genus-specific probes have also been developed based on 23S rRNA gene (Mehling et al., 1995) and 5S rRNA gene (Park et al., 1991) sequences. The reclassification of the genera *Chainia*, *Elytrosporangium*, *Kitasatoa*, *Microellobosporia*, and *Streptoverticillium* into the genus *Streptomyces* was confirmed using 5S rRNA gene sequence data (Park et al., 1991).

At present, complete 16S rRNA gene sequences for almost all *Streptomyces* type strains are available from public databases. However, the variation in the 16S rRNA genes – even in the variable regions – is too limited to help resolve problems of species differentiation and to establish taxonomic structure within the genus (Anderson and Wellington, 2001; Stackebrandt et al., 1991a, 1991b, 1992; Witt and Stackebrandt, 1990). The situation is complicated by the fact that *Streptomyces* species may harbor different 16S rRNA gene sets, for example, *Streptomyces coelicolor* A3(2), "*Streptomyces lividans*", and several other *Streptomyces* species contain six ribosomal rRNA gene sets. Each set of rRNA genes comprises one gene copy for 16S, 23S, and 5S rRNA (van Wezel et al., 1991) and lacks tRNA genes.

Other genes can be used to establish inter- and intraspecies level relationships within the genus. Hatano et al. (2003) examined the partial sequences of the *gyrB* gene of 64 whorl-forming streptomycetes. This gene represents the structural gene of the B subunit of DNA gyrase. Most members of the 46 species, eight subspecies, and 13 species with names that have not been validly published (including 10 strains examined by the ISP) were assigned to two major groups. The larger group, which consisted of typical whorl-forming species (59 strains), was subdivided into six major clusters of three or more species, seven minor clusters of two species, and five single-member clusters at the 97% *gyrB* sequence similarity level. The major clusters contained *Streptomyces abikoensis*, *Streptomyces cinnamoneus*, *Streptomyces distallicus*, *Streptomyces griseocarneus*, *Streptomyces hiroshimensis*, and *Streptomyces netropsis* strains, results that were in line with phenotypic data.

With the exception of the *Streptomyces distallicus* cluster (which was divided phenotypically into the *Streptomyces distallicus* and *Streptomyces stramineus* subclusters) and the *Streptomyces netropsis* cluster (which was divided into the *Streptomyces netropsis* and *Streptomyces eurocidicus* subclusters), members of each of the clusters resembled one another closely, as did members of the minor clusters. Hatano and his colleagues classified 59 strains of typical whorl-forming *Streptomyces* species into the following 18 species [including subjective synonym(s)]: *Streptomyces abikoensis*, *Streptomyces ardus*, *Streptomyces blastmyceticus*, *Streptomyces cinnamoneus*, *Streptomyces eurocidicus*, *Streptomyces griseocarneus*, *Streptomyces hiroshimensis*, *Streptomyces lilacinus*, "*Streptomyces luteoreticuli*", *Streptomyces luteosporeus*, *Streptomyces mashuensis*, *Streptomyces mobaraensis*, *Streptomyces morookaense*, *Streptomyces netropsis*, *Streptomyces orinoci*, *Streptomyces stramineus*, *Streptomyces thioluteus*, and *Streptomyces viridiflavus* (Table 272). In addition, all of the strains, which showed 98.5–100% *gyrB* sequence similarities, had high DNA–DNA similarities (70–100%), indicating that *gyrB* sequences give a better resolution than corresponding 16S rRNA gene sequences.

Other conserved genes that are prime targets for taxonomic studies include the housekeeping genes (e.g. elongation factors and ATPase subunits; Ludwig and Schleifer, 1994) and tryptophan synthase genes (Huddleston et al., 1997), which were used to determine the phylogeny of streptomycin-producing streptomycetes and provide evidence for horizontal transfer of antibiotic resistance genes. Guo et al. (2008) sequenced five housekeeping genes (*atpD*, *gyrB*, *recA*, *rpoB*, *trpB*) and the corresponding 16S rRNA genes of 55 *Streptomyces* strains classified in the *Streptomyces griseus* clade. The strains were assigned to four clusters that contained strains with identical 16S rRNA gene sequences, but these results were not congruent with those based on the sequences of the individual or from corresponding concatenated gene sequences. Some of the strains with identical 16S rRNA gene sequences were assigned to different clusters in the housekeeping gene sequence trees. The trees based on individual gene sequences gave a higher resolution between strains than the concatenated tree. The authors concluded that phylogenetic trees generated on more than one gene sequence are more reliable and give a higher resolution power and topological stability.

Kim et al. (2004) analyzed the sequences of 16S rRNA and RNA polymerase β-subunit genes (*rpoB*) of 57 *Streptomyces* strains, five *Kitasatospora* strains, and a single *Micromonospora* strain and found that the resultant phylogenetic trees had similar topologies. They also found good congruence between the *rpoB* sequence and corresponding numerical phenetic data of Williams et al. (1983a). The five *Kitasatospora* strains were clearly separated from the *Streptomyces* strains in the *rpoB* gene tree. Such results show that sequence analysis of additional genes (i.e. other housekeeping genes) will help to give a better insight into the intraspecific structure of the genus *Streptomyces* (Stackebrandt et al., 2002).

Rapid methods for gene analysis in streptomycete taxonomy. Several alternative methods for gene analysis have been described which do not involve sequencing. These methods are based on either restriction analysis (Clarke et al., 1993; Fulton et al., 1995) or specialized gel electrophoresis techniques which are used to monitor the mobility of products (Hain et al., 1997; Heuer et al., 1997). Clarke et al. (1993) used a combination of *Bgl*I, *Eco*RI, *Pst*I, and *Pvu*II to obtain restriction fragment length polymorphism (RFLP) patterns of purified rRNA extracted from members of the *Streptomyces albidoflavus* cluster [subgroups 1A and 1B of Williams et al. (1983a)] and were able to differentiate between phenotypically similar strains, although profiles varied considerably between *Streptomyces albidoflavus* species-groups. Ribosomal restriction analysis of 98 named streptomycete strains, including members of cluster-groups A (comprising clusters 1–41) and F (comprising clusters 55–67) of Williams et al. (1983a) and some other strains, was performed by Fulton et al. (1995) using *Mse*I fingerprints of rRNA operons (RiDiTS) and 11 pattern types with varying degrees of similarity to the Williams subclusters were highlighted. Cluster-groups A and F were differentiated, albeit at a low resolution (70% similarity), but individual clusters could not be distinguished.

Further methods used to compare genotypic variation amongst streptomycetes include denaturing gradient gel electrophoresis (DGGE; Muyzer et al., 1993) with or without DNA-binding agents (Hain et al., 1997). Anderson and Wellington (2001) recommended DGGE in combination with other techniques. This method uses variable 16S rRNA regions and enables the delimitation of genus and species-groups. Isolates ASB33, ASB37, and ASSF22 were allocated to *Streptomyces albidoflavus*, *Streptomyces griseoruber*, and *Streptomyces albidoflavus*, respectively, by using a combination of techniques, including numerical taxonomy, PFGE, and sequence comparisons (Huddleston et al., 1997; Huddleston et al., 1995).

Additional comments. Nowadays, often the first step in characterization of an isolate is the determination of the 16S rRNA gene sequence. Those isolates that may represent novel species are then further characterized in order to find additional markers which are different from those reported for already established taxa. In several cases, only a very restricted set of phenotypic differences are found, especially within the genus *Streptomyces*, and hence the classification of novel taxa is based largely on the 16S rRNA gene sequence differences. More and more, additional (housekeeping) gene sequence differences are also reported, which are sometimes regarded as sufficient for the delineation of novel species. There is clearly a current trend to delineate species more and more on the basis of the genotype.

However, recent analyses have shown that, although the 16S rRNA gene sequence has been widely accepted as the "backbone" of bacterial systematics as part of the often called "tree of life", in the light of genome data the concept of a single universal tree of life appears increasingly obsolete, especially given the impact of lateral or horizontal gene transfer events (see, e.g. Bapteste et al., 2009; Bapteste and Boucher, 2008; Boucher and Bapteste, 2009; Dagan et al., 2008; Fournier and Gogarten, 2010; Fournier et al., 2009; Kreimer et al., 2008; Wolf et al., 2002; and others for a more detailed discussion). It is methodologically difficult to infer horizontal or lateral gene transfer unless one has an *a priori* hypothesis of relationship that indicates that the presumptive transferred genes are not homologs. But there is no doubt that horizontal gene transfer (HGT) is widespread in the microbial world. HGT can result in either acquisition of new genetic material or homologous replacement of existing genes. The evolutionary significance of homologous recombination

in a population can be quantified by examining the relative rates at which polymorphisms are introduced from recombination (rho) and mutation [theta(w)]. In the study of Doroghazi and Buckley (2010), multilocus sequence analysis (MLSA) was used to quantify both intraspecies and interspecies homologous recombination among streptomycetes and some other Gram-stain-positive bacteria. These authors found that intraspecies recombination in *Streptomyces flavogriseus* isolated from soils at five locations spanning 1000 km showed a >99.8% nucleotide identity across the loci examined. The authors found remarkable levels of gene exchange within *Streptomyces flavogriseus* and that the population was in linkage equilibrium (standardized index of association=0.0018), providing evidence for a freely recombining sexual population structure. As an even more interesting result, extensive interspecies homologous recombination was found among different *Streptomyces* species summing up to 40% of housekeeping-genes that had been acquired through HGT. This recombination rate found for these named species exceeded by far that observed within many species of bacteria. Hence, it was concluded that this pattern of gene exchange and recombination clearly shaped the evolution of streptomycetes and this has also a tremendous effect on classification based on sequence data of housekeeping genes.

Molecular data can provide an enormous amount of information. However, at this point, we are far from able to interpret these data, especially the information behind them, well enough to draw decisive conclusions. There are numerous open questions, e.g. which genes belong to the conserved genome core and are considered probably useful to define a taxon and which belong to accessory dispensible genetic elements? The "overall" impact of processes such as lateral gene transfer, gene duplication, recombination, and rearrangements of genes in the genome is not clear and may vary considerably in different lineages (see Bapteste et al., 2009; Dagan et al., 2008; and other publications). In addition, the presence of genes and gene clusters (whether expressed or "silent") can have a totally different biological meaning and the roles of structural elements (some of them phenotypically recognizable by the so-called "chemotaxonomic" methods) and biochemical pathways (also recognized by studying the phenotype at different levels) should be consistent with the underlying genetic data, which is essentially the aim of a "polyphasic taxonomic" study.

Despite the advantages of molecular methods (including the generation and analyses of whole genome sequence data), it is often impossible to deduce phenotypic properties from the presence or absence of genes and gene clusters, because genes do not exist for their own sake. This is especially true for seemingly simple, but nevertheless "complex" phenotypic properties, like temperature, NaCl, or pH tolerances, and some complex chemotaxonomic features (just to name a few), which may be affected by very different and complex regulatory biochemical networks and are based on the underlying genetic potential and expression network. It should be emphasized again, as also pointed out by Tindall et al. (2010), that experience gained over the past six decades has continued to demonstrate the value of comparing different datasets and also of basing the description and delineation of taxa on as wide a dataset as possible. Only a combination of data acquired from DNA-based methods (DNA–DNA hybridization, gene sequences, genomic fingerprints) and phenotyping (chemotaxonomic, physiological, and morphological traits) provides a sound basis for the taxonomy of the prokaryotes in general, including streptomycetes (Tindall et al., 2010).

Differentiation and characteristics of the species of the genus *Streptomyces*

It is difficult to identify *Streptomyces* species, partly due to the high number of species with validly published names (Table 272). Most of these species are named on the basis of a single strain description and, hence, at present, it is not possible to recommend a single method or even a set of methods for identification at the species level. Species allocations on the basis of the results of one or few methods should be regarded with care. The ICSP Subcommittee on the Systematics of *Streptomycetaceae* (Kämpfer and Labeda, 2003) has recommended that more genomic information should be evaluated before a species concept is formulated for the genus *Streptomyces.* It was agreed "that the proposal of new species should only be accepted on the basis of very careful studies done with sufficient practice and considering all other species".

Sequence analysis of the rRNA gene has revolutionized our insight into phylogenetic lineages of major taxonomic groups, but this method does not have sufficient resolving power to delimit *Streptomyces* species. It is clearly not possible to assign new strains to existing species solely on the basis of this molecule, though trees are a useful visual aid for placing members of putative novel species next to their nearest relatives. Even if results from the application of different treeing algorithms differ, the judgment of what is a novel species and which are its closest relatives will be decided on the basis of individual sequence homologies, and on complementary genetic (e.g. DNA–DNA hybridization) data.

Given the difficulties of interpreting the 16S rRNA, the descriptions of all species with validly published names are presented in the species descriptions in alphabetical order. The species descriptions include details of 16S rRNA similarities of related species based on pairwise comparisons. A grouping of the species was performed on the basis of a phylogenetic analysis using the 16S rRNA gene sequences. Groups which were relatively stable on the basis of different treeing methods are given in Figure 339. A table with all *Streptomyces* species, grouped according to the clusters, lists further information to all *Streptomyces* species, including type strain numbers, their inclusion in the numerical taxonomic studies of Williams et al. (1983a) and Kämpfer et al. (1991), 16S rRNA gene sequence accession numbers, DNA–DNA hybridization, and numerous other studies (Table 272). Additional genotypic and phenotypic data can be obtained from these studies.

Acknowledgements

I thank Dr Jean Euzéby for his advice on numerous nomenclatural issues and for permission to include some information given on his website (http://www.bacterio.cict.fr/) in some of the species descriptions. I am indebted to Dr Wolfgang Ludwig for preparing the phylogenetic tree (Figure 339) and his help in interpreting sequence data, and to Professor Michael Goodfellow for his excellent and very helpful comments to this chapter. Many thanks go to my coworkers Dr Nicole Lodders, Dr Kathrin Thummes, Kerstin Fallschissel, and Corina Lang for support in writing and proofreading this chapter.

List of species of the genus *Streptomyces*

1a. **Streptomyces albus subsp. albus** (Rossi Doria 1891) Waksman and Henrici 1943, 339^AL^ ["*Streptotrix alba*" (*sic*) Rossi Doria 1891, 421]

al′bus. L. masc. adj. *albus* white.

Spore chains in Section *Spirales*. Spirals are most abundant on oatmeal agar and may be poorly developed on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Mature spore chains generally have 10–50 spores per chain, but shorter chains may be common on some media. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on oatmeal agar and salts-starch agar; White or Yellow color series on yeast-malt agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Reports vary on utilization of L-arabinose and raffinose. No growth or only traces of growth with iso-inositol, rhamnose, and sucrose.

Type strain shows the highest sequence similarity to: *S. almquistii*, AB184258, 100%; *S. rangoonensis*, AB184295, 100%; *S. gibsonii*, AB184663, 100%; *S. flocculus*, AB184272, 99.8%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.164, ATCC 25426, ATCC 3004, IMRU 3004, CBS 410.63, CBS 924.69, BCRC (formerly CCRC) 10802, CCUG 33990, CECT 3077, CIP 104432, DSM 40313, HUT 6613, IFM 1119, IFO (now NBRC) 13014, NBRC 3710, IMET 40241, JCM 4450, JCM 4177, KCTC 1082, NCIMB 9558, NRRL B-1811, NRRL B-2208, NRRL-ISP 5313, RIA 1206, VKM Ac-35.

Sequence accession no. (16S rRNA gene): AJ621602.

1b. **Streptomyces albus subsp. pathocidicus** Nagatsu, Anzai and Suzuki 1962, 105^AL^

pa.tho.ci′di.cus. Gr. n. *pathos* disease; L. suff. -*cida* (from L. v. *caedo*, to cut or kill) murderer, killer; L. masc. suff. -*icus* suffix used with the sense of belonging to; N.L. masc. adj. *pathocidicus* belonging to pathocide, but obviously referring to the antibiotic pathocidin.

Aerial mycelium has a closed spiral or an open loop on glucose-asparagine agar and starch agar. Conidia are elliptical, 1.0 × 1.3–1.4 × 1.8 μm in size, and show a chain-like growth. Usually grows at 25–30°C on various media. At first, it has no color, then it changes from white to pale yellow, with white aerial mycelium. Hydrolyzes starch, does not liquefy gelatin, and forms small amounts of nitrite.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1633, ATCC 14510, BCRC 12331, CIP 104431, DSM 40799, NBRC 13812, JCM 4166, KCTC 9671, VKM Ac-598.

Sequence accession no. (16S rRNA gene): AB184501.

2. **Streptomyces abikoensis** (Umezawa, Tazaki and Fukuyama 1951) Witt and Stackebrandt 1991, 456^VP^ (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces abokobensis*" Umezawa, Tazaki and Fukuyama 1951, 333; *Streptoverticillium abikoense* Locci, Baldacci and Petrolini Baldan 1969, 59; "*Verticillomyces abikobensis*" Shinobu 1965, 96)

a.bi.ko.en′sis. N.L. masc. adj. *abikoensis* of or belonging to Abiko (named after Abiko, Japan).

Spore chains are straight. Reverse colors tend to appear darker. Aerial mycelium can be beige, pale pink to pinkish white. Soluble pigments are present on Bacto Emerson agar. Utilizes starch, casein, and, more readily, gelatin. Growth at 37°C is the same as that at 27°C; however, aerial mycelium is less abundant and lighter in color. Brown soluble pigments are produced at 37°C on potato-glucose agar (Baldacci et al., 1954). The type strain produces abikoviromycin and exhibits polyenic anti-fungal activity.

Type strain shows the highest sequence similarity to: *S. lilacinus*, AB184819, 99.7%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99.7%%; *S. ehimensis*, AY999834, 99.6%; *S. sapporonensis*, AB184508, 99.5%; *S. hiroshimensis*, AB184789, 99.5%; *S. caeruleus*, EF178675, 99.5%; *S. luteireticuli* AB249969, 99.3%; *S. thioluteus*, AB184753, 99.3%; *S. varsoviensis*, DQ026653, 99.2%; *S. morookaense* AJ781349, 99.1%; *S. lavenduligriseus*, DQ442515, 99.1%; *S. cinnamoneus*, AB184850, 99.1%; *S. blastmyceticus*, AY999802, 99%; *S. pseudoechinosporeus*, AB184100, 99%; *S. olivoverticillatus*, AB184636, 99%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1162, ATCC 12766, CBS 487.62, BCRC 12461, DSM 40831, NBRC 13860, JCM 4002, KCTC 9662, KCTC 9741, NRRL B-1518, NRRL B-2113, PCM 2364, RIA 497.

Sequence accession no. (16S rRNA gene): AB184537.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces abikoensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces abikoensis*" Umezawa, Tazaki and Fukuyama (1951).

According to Hatano et al. (2003), *Streptomyces abikoensis* (Umezawa et al. 1951) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces ehimensis* corrig. (Shibata et al. 1954) Witt and Stackebrandt 1991, of *Streptomyces luteoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991, of *Streptomyces olivoreticuli* (Arai et al. 1957) Witt and Stackebrandt 1991, and of *Streptomyces parvisporogenes* (Locci et al. 1969) Witt and Stackebrandt 1991. Hatano et al. (2003) also propose that *Streptomyces abikoensis* (Umezawa et al. 1951) Witt and Stackebrandt 1991 be a heterotypic synonym of "*Streptomyces olivoreticuli* subsp. *cellulophilus*" (NBRC 15929), of "*Streptomyces paucisporogenes*" (NBRC 13070), of "*Streptomyces takataensis*" (NBRC 13470), of "*Streptoverticillium rubrireticuli*" (NBRC 13082), and of "*Streptoverticillium rubroverticillatum*" (NBRC 15818). In the paper by Hatano et al. (2003), "*Streptomyces olivoreticuli* subsp. *cellulophilus*" is not in quotes. However, this name has no standing in bacterial nomenclature.

3. **Streptomyces aburaviensis** Nishimura, Kimura, Tawara, Sasaki, Nakajima, Shimaoka, Okamoto, Shimohira and Isono 1957, 206[AL].

a.bu.ra.vi.en′sis. N.L. masc. adj. *aburaviensis* of or belonging to Aburabi, Shiga Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately long with 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is yellowish brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (this pigment is not a pH indicator).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment other than trace of yellow is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Growth on carbon utilization media is generally poor. D-Glucose, D-fructose, and D-xylose are utilized for growth. Reports vary from no growth to traces of growth on L-arabinose, sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. herbaricolor*, AB184801, 99.6%; *S. indigoferus*, AB184214, 99.6%; *S. purpureus*, AJ781324, 99.5%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.5%; *S. xanthocidicus*, AY999858, 99.4%; *S. psammoticus*, AY999862, 99.1%; *S. purpeofuscus*, AJ781364, 99.1%; *S. avellaneus*, AB184413, 99%. Type strain shows the highest sequence similarity to following *Kitasatospora* species: *Kitasatospora kifunensis*, AB022874, 99.3%; *Kitasatospora gansuensis*, AY442265, 99%.

Source: soil from Japan.

DNA G+C content (mol%): not known.

Type strain: AS 4.1469, ATCC 23869, CBS 280.60, CBS 608.68, BCRC 11617, CECT 3315, DSM 40033, IFM 1083, NBRC 12830, IMET 43081, JCM 4613, JCM 4170, KCTC 9663, LMG 19305, NRRL B-2218, NRRL-ISP 5033, RIA 1107, RIA 732, VKM Ac-1868.

Sequence accession no. (16S rRNA gene): AY999779.

4a. **Streptomyces achromogenes subsp. achromogenes** (*sic*) Okami and Umezawa *in* Umezawa, Takeuchi, Okami and Tazaki 1953, 268[AL]

a.chro.mo′ge.nes. Gr. pref. *a-* not; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce), producing; N.L. adj. *achromogenes* not producing color.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally comprise 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer recorded some loops or hooks on salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar, tyrosine agar, and other organic media. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salt-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, D-xylose, and raffinose. Variable reports of slight growth with rhamnose and iso-inositol.

Type strain shows the highest sequence similarity to: *S. cellostaticus*, AB184192, 99%; *S. niveoruber*, DQ445796, 99%.

Sequence accession no. (16S rRNA gene): AB184109.

4b. **Streptomyces achromogenes subsp. rubradiris** Bhuyan, Owen and Dietz 1965, 95[AL]

rub.ra.di′ris. L. adj. *ruber -bra -brum* red; L. n. *iris* the rainbow; N.L. n. *rubradiris* (*sic*) reddish rainbow.

S. achromogenes and its variants are melanin-positive and have gray aerial growth containing chains of oval and oblong spores. These chains contain more than 10 spores born in sporophores characterized as open loops. The cultures grow well at temperatures ranging from 18 to 37°C, but do not grow at 55°C. The effect of several nitrogen sources on antibiotic production was investigated in a medium containing starch as the carbohydrate source. A medium with Soludri, cornsteep liquor, $NaNO_3$, and starch gave the highest yields. Good growth and the proper pH level for antibiotic production were obtained in all cases, except when Wilson peptone liquor or Pharmamedia were used.

The effect of several carbohydrate sources was studied in a medium containing cornsteep liquor, Soludri, and $NaNO_3$. Cerelose or starch at a level of 1% were the preferred carbon sources. Equivalent growth was obtained in all cases, except for very heavy growth in glycerol-containing medium. Fermentations incubated at 25°C gave higher titers that those at 28 or 32°C. Incubation temperature during the first 2 d was critical for antibiotic production. Thus, the fermentation transferred to 28°C after 2 d of growth at 25°C gave the same yields as the fermentation at 25°C (21 µg/ml). However, when the fermentation was transferred to 25°C after 2 d growth at 28°C, lower yields (4 µg/ml) were obtained. Maximal yields were obtained when the pH was maintained near 8 during the production phase. Thus, when the pH was maintained at 7.2 until the third day by raising the starch concentration in the medium to 4% or by intermittent addition of acid, only 3 µg/ml antibiotic was produced as compared with 21 µg/ml when 1% starch was used.

During fermentation obtained with a medium containing starch, cornsteep liquor, Soludri, and $NaNO_3$, most of

the carbohydrate was used during the first 24 h, after which little sugar was utilized. Free ammoniacal nitrogen utilized during the first 24 h resulted in a decrease in pH. Release of NH_3 after this period raised the pH on the second day to above 8, where it remained during the rest of the fermentation. Rubradirin was produced mainly during the later phase of the fermentation to give a maximal titer of 21 µg/ml after 4 d.

Rubradirin was active *in vitro* mainly against Gram-stain-positive organisms. It was also active *in vitro* against two clinical strains of *Staphylococcus aureus* which were resistant to several antibiotics. It was inactive at 100 µg/ml against *Escherichia coli*, *Salmonella paratyphi*, *Proteus vulgaris*, *Salmonella typhi*, *Klebsiella pneumoniae*, and *Pseudomonas aeruginosa*. The antibiotic inhibited *Nocardia asteroides* at 1 µg/ml, but was inactive against a group of fungi at 1 mg/ml. Rubradirin was not cross-resistant with penicillin, streptomycin, erythromycin, chloramphenicol, or albamycin.

In vivo, mice infected with *Staphylococcus aureus* and *Streptococcus pyogenes* were protected by non-toxic doses of rubradirin. The antibiotic was active both by the oral and subcutaneous routes. It was inactive against *Pasteurella multocida in vivo* and *in vitro*. Although the antibiotic was active against *Mycobacterium tuberculosis* H 37-RV *in vitro*, it was inactive against it *in vivo*.

The type strain shows the highest sequence similarities to: *S. bangladeshensis*, AY750056, 99%; *S. glomeratus*, AB249917, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1601, CBS 566.70, CECT 3075, DSM 40789, NBRC 14000, JCM 4955, KCTC 9742, NCIMB 9516, NRRL 3061.

Sequence accession no. (16S rRNA gene): AY999846.

5. **Streptomyces acidiscabies** Lambert and Loria 1989a, 395[VP]

a.ci.di.sca′bi.es. L. adj. *acidus* sour, acid; L. n. *scabies* scab, mange; N.L. n. *acidiscabies* acid scab, referring to the ability of the organism to cause acid scab of potatoes.

Spores are 0.4–0.5 × 0.6 or 0.9–1.1 µm, smooth, and white (reddish on certain high pH media) and are borne in mature flexuous chains containing 20 or more spores. A diffusible pigment is produced which is red above pH 8.3 and golden-yellow below pH 8.3. Melanin is not produced. L-Arabinose, D-fructose, D-glucose, D-mannitol, rhamnose, sucrose, and D-xylose are used as carbon sources, but not raffinose. *S. acidiscabies* differs from all other streptomycetes that cause typical raised or pitted symptoms and have white spores, red pigment, and acid tolerance. It differs in at least one major characteristic from all other strains described in the ISP having red pigments or spores. *Streptomyces acidiscabies* is placed in the genus *Streptomyces* as it possesses typical morphology and cell walls with the LL-A_2pm isomer. To date, *Streptomyces acidiscabies* has been isolated only from potatoes (*Solanum tuberosum*), and its pathogenicity towards other species has not been determined. The ability of this species to persist in soil is relatively poor and it is usually transmitted by infected seed tubers.

The type strain shows no sequence similarity over 99%.

Source: potatoes.

DNA G+C content (mol%): 71.0.

Type strain: RL-110, ATCC 49003, ICMP 12536, DSM 41668, JCM 7913, KCTC 9736, LMG 19856, NRRL B-16524.

Sequence accession no. (16S rRNA gene): D63865.

6. **Streptomyces acrimycini** (Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 65[AL] ("*Actinomyces acrimycini*" Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 140).

a.cri.my.ci′ni. L. adj. *acer-cris-cre* sharp, keen, pungent; N.L. suff. *-mycinum*, -mycin (antibiotics produced by *Streptomyces* strains); N.L. gen. n. *acrimycini* of the sharp antibiotic.

Spore chains in Section *Spirales*, with many loose spirals, but spore chains representative of Section *Retinaculiaperti* and some flexuous chains are also observed. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is hairy.

Color of colony: aerial mass color in the Green color series on yeast-malt agar and salts-starch agar; Green or Gray series on oatmeal agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Substrate pigment is not a pH indicator (one observer reports a slight change from green to light green with addition of 0.05 M NaOH).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar or tyrosine agar. No pigment is found in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose and raffinose.

7. **Streptomyces aculeolatus** Shomura, Gomi, Ito, Yoshida, Tanaka, Amano, Watabe, Ohuchi, Itoh, Sezaki, Takebe and Uotani 1988, 136[VP] (Effective publication: Shomura, Gomi, Ito, Yoshida, Tanaka, Amano, Watabe, Ohuchi, Itoh, Sezaki, Takebe and Uotani 1987, 738.)

acu.le.o.la′tus. N.L. masc. adj. *aculeolatus* (probably used in the place of the Latin adjective *aculeatus*) somewhat spiny, referring to the spore surfaces.

Mature spore chains have 10 or more spores per chain. This morphology is observed in sucrose-nitrate agar, glycerol-asparagine agar, and inorganic salts-starch agar. Spores are ellipsoidal in shape, 0.8–1.2 × 1.0–1.6 µm in size. Surface irregularities on spores are intermediate between warts and spines. Sporangia, flagellated spores, and sclerotic granules are not observed. Aerial mass color is in the White, Yellow, or Red color series. Vegetative mycelium is well developed and branched. The hyphae do not fragment into coccoid or bacillary elements. Aerial mycelium is simply branched and terminates in open or closed coils. The reverse side of colonies varies from pale yellow to orange depending on the medium. This orange color is somewhat pH-sensitive, changing from orange to reddish with addition of 0.05 M NaOH and from orange to yellowish with addition of 0.05 M HCl. Light brownish orange, water-soluble pigment is occasionally produced. On ISP 9 medium, utilizes D-glucose, D-fructose, D-xylose, L-arabinose, D-mannitol, raffinose, and rhamnose, but not iso-inositol or sucrose. Grows within the temperature range 15–37°C, with optimum growth at 26–30°C. Positive for hydrolysis of starch and liquefaction of gelatin. Reduction of nitrate, peptonization and coagulation of milk, and formation of melanoid pigment are all negative. Tolerates 3% NaCl, but no growth occurs on more than 4% NaCl. LL-A_2pm is detected in whole-cell hydrolysates of the culture.

The type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: SF2415, DSM 41644, NBRC 14824, JCM 6055, KCTC 9680.

Sequence accession no. (16S rRNA gene): AB184624.

8. **Streptomyces afghaniensis** Shimo, Shiga, Tomosugi and Kamoi 1959, 1[AL]

af.gha.ni.en′sis. N.L. masc. adj. *afghaniensis* of or belonging to Afghanistan, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*, but short spore chains usually result in hooks, incomplete spirals, or spirals with only one or two turns. Short, straight, and flexuous chains of only a few spores are common, but hooks and loops of wide diameter as found in *Retinaculum-Apertum* type cultures are not found. Spore chains are short, often with only 3–10 spores per chain, but more than 10 spores may be found on some chains. This morphology is best developed on oatmeal agar and salts-starch agar. Spore surface is spiny.

Color of colony: aerial mass color in the Blue color series on oatmeal agar. Immature aerial mycelium or mycelium producing few spores is in the Yellow color series. Observers have reported both Blue and Yellow color series for yeast-malt agar and salts-starch agar. Mature spores are not usually found on glycerol-asparagine agar. Reverse side of colony is grayed yellow on oatmeal agar, modified to orange or reddish brown on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; this pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and peptone-yeast broth. Orange to red or brown pigments are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; these pigments are not pH-sensitive when tested with 0.05 M HCl or NaOH.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. africanus*, AY208912, 99.8%; *S. levis*, AB184670, 99.2%; *S. brasiliensis*, AB249981, 99.1%; *S. tuirus*, AB184690, 99.1%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99%; *S. cellulosae*, DQ442495, 99%; *S. azureus*, EF178674, 99%; *S. capillispiralis*, AB184577, 99%; *S. gancidicus*, AB184660, 99%; *S. pseudogriseolus*, DQ442541, 99%; *S. roseoviolaceus*, AJ399484, 99%; *S. violaceus*, AB184315, 99%; *S. janthinus*, AB184851, 99%; *S. hawaiiensis*, AB184143, 99%.

Source: soil from Afghanistan.

DNA G+C content (mol%): not known.

Type strain: ATCC 23871, CBS 610.68, DSM 40228, NBRC 12831, JCM 4340, NRRL B-5621, NRRL-ISP 5228, RIA 1169.

Sequence accession no. (16S rRNA gene): AJ399483.

9. **Streptomyces africanus** Meyers, Goodwin, Bennett, Aken, Price and Van Rooyen 2004, 1534[VP]

af.ri.ca′nus. L. masc. adj. *africanus* of Africa.

Spirales-type spore chains with spiny spore sheaths are produced. Aerial mycelium is blue and substrate mycelium is yellow. The color of the substrate mycelium is not pH-sensitive. Verticils are not present. The mycelium does not fragment. No diffusible pigments are produced on glycerol-asparagine agar or on any other medium tested. Melanin pigment is not produced on peptone-yeast extract-iron agar or on tyrosine agar. The cell wall contains LL-A_2pm (cell-wall type I); there are no diagnostic sugars. Excellent growth occurs on inorganic salts-starch agar. Very good growth occurs on yeast extract-malt extract agar, oatmeal agar, and Czapek's solution agar. Growth is good on Bennett's agar. Growth on glycerol-asparagine agar is moderate. Grows in the presence of 2-phenylethanol (0.3%), 7% NaCl (but not 10%), carbenicillin (100 µg/ml) cefataxime (100 µg/ml),

D-cycloserine (50 μg/ml), nalidixic acid (25 μg/ml), oleandomycin (100 μg/ml), and penicillin G (10 IU/ml). Grows at pH 4.3 and 45°C, but not at 4°C or in the presence of sodium azide, capreomycin (20 μg/ml), cephaloridine (100 μg/ml), chloramphenicol (50 μg/ml), erythromycin (50 μg/ml), gentamicin (100 μg/ml), kanamycin (10 μg/ml), lincomycin (100 μg/ml), neomycin (50 μg/ml), phenol (0.1%), rifampin (50 μg/ml), spectinomycin (20 μg/ml), streptomycin (100 μg/ml), tobramycin (50 μg/ml), or vancomycin (50 μg/ml). The organism degrades adenine, esculin, arbutin, casein, DNA, gelatin, hypoxanthine, starch, Tween 80, and L-tyrosine, but not allantoin, cellulose, guanine, urea, xanthine, or xylan. Utilizes adonitol, (+)-L-arabinose, (+)-D-cellobiose, (−)-D-fructose, (+)-D-galactose, glycerol, *myo*-inositol, inulin, lactose, maltose, D-mannitol, (+)-D-mannose, (+)-D-melibiose, methyl α-D-glucoside, raffinose, (+)-L-rhamnose, (−)-D-ribose, salicin, sodium acetate, sodium butyrate, sodium citrate, sodium DL-malate, sodium malonate, sodium propionate, sodium pyruvate, sodium salicylate, sodium succinate, sucrose, trehalose and (+)-D-xylose as sole carbon sources, but not *meso*-erythritol, (+)-D-melezitose, sodium benzoate, sodium formate, sodium maleate, sodium oxalate, sodium (+)-L-tartrate, (−)-L-sorbose, or xylitol. Utilizes 4-amino-n-butyric acid, DL-α-amino-n-butyric acid (weak growth), L-arginine, L-cysteine, L-histidine, L-hydroxyproline (weak growth), L-methionine, DL-ornithine, L-phenylalanine, potassium nitrate, L-serine, L-threonine, and L-valine as sole nitrogen sources. Tests for nitrate reductase and H_2S production are positive. Pectin is hydrolyzed, but hippurate is not. Protease, lipase, and lecithinase activities are produced on egg-yolk agar (the proteolytic reaction is weak). Weak antibiotic activity is exhibited against *Enterococcus faecium*, but no antibiotic activity is observed against *Escherichia coli* ATCC 25922 or *Pseudomonas aeruginosa* ATCC 27853.

Type strain shows the highest sequence similarity to: *S. afghaniensis*, AJ399483, 99.8%; *S. janthinus*, AB184851, 99.2%; *S. roseoviolaceus*, AJ399484, 99.2%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.2%; *S. levis*, AB184670, 99.2%; *S. violaceus*, AB184315, 99.2%; *S. brasiliensis*, AB249981, 99.2%; *S. azureus*, EF178674, 99.1%; *S. tuirus*, AB184690, 99.1%; *S. mutabilis*, EF178679, 99%; *S. hawaiiensis*, AB184143, 99%; *S. pseudogriseolus*, DQ442541, 99%; *S. capillispiralis*, AB184577, 99%; *S. gancidicus*, AB184660, 99%; *S. cellulosae*, DQ442495, 99%.

Type strain shows DNA–DNA similarity to: *S. afghaniensis* NRRL B-5621^T, 46.2 ± 0.9%; "*S. steffisburgensis*" NRRL ISP 5547, 38.4 ± 0.5%.

Source: not known.

DNA G+C content (mol%): 73.2.

Type strain: CPJVR-H, DSM 41829, JCM 13243, NBRC 101005.

Sequence accession no. (16S rRNA gene): AY208912.

10. **Streptomyces alanosinicus** Thiemann and Beretta 1966, 158[AL]

a.la.no.si′ni.cus. N.L. n. *alanosinum* alanosine (name of an antibiotic); L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *alanosinicus* belonging to alanosine.

Spore chains in Section *Spirales*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but sporulating aerial mycelium is thin or absent on glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red color series (4ec, grayish yellowish pink, or 3ca, pale orange yellow) on yeast-malt agar, oatmeal agar, and salts-starch agar; sporulating aerial mycelium is thin or absent on glycerol-asparagine agar. Reverse side of colony has no distinctive pigments (moderate reddish brown to strong brown on yeast-malt agar; pale grayish yellow to light yellowish brown or olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth, but reaction may be delayed or weak in tyrosine agar. No pigment is found in medium in salts-starch agar or glycerol-asparagine agar. Some yellow pigment may or may not be seen in yeast-malt agar and oatmeal agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Reports vary on utilization of sucrose; no growth or only traces of growth with rhamnose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Sequence accession no. (16S rRNA gene): AB184442.

11. **Streptomyces albaduncus** Tsukiura, Okanishi, Ohmori, Koshiyama, Miyaki, Kitazima and Kawaguchi 1964b, 41[AL]

al.ba.dun′cus. L. adj. *albus* white; L. adj. *uncus* hooked, crooked; N.L. masc. adj. *albaduncus* (*sic*) white, hooked, probably referring to color of aerial mycelium and nature of spore chains of the organism.

Spore chains in Section *Retinaculiaperti* to *Spirales*. Short spore chains are flexuous or form hooks, loops, and incomplete or imperfect spirals. True spirals are not reported. Mature spore chains generally contain more than 10 spores per chain but are shorter than those found in *Retinaculum-Apertum* type cultures. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny with numerous long spines.

Color of colony: aerial mass color in the White or Yellow or Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The nearest matching color tab in the Yellow series is 2ba, pale yellow, and in the Gray color series is d, light gray, 2fe, medium gray, or 3fe, light brownish gray. Reverse side of colony has no distinctive pigments (grayish yellow to yellowish brown, olive brown, or strong brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment is found in the medium in yeast-malt

agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with sucrose or raffinose.

Type strain shows the highest sequence similarity to: *S. griseoloalbus*, AB184275, 100%; *S. matensis*, AB184221, 99.3%; *S. paradoxus*, AB184628, 99.2%; *S. pseudogriseolus*, DQ442541, 99.2%; *S. gancidicus*, AB184660, 99.2%; *S. capillispiralis*, AB184577, 99.1%; *S. heliomycini*, AB184712, 99%; *S. malachitofuscus*, AB184282, 99%; *S. griseoflavus*, AJ781322, 99%; *S. ambofaciens*, M27245, 99%; *S. cellulosae*, DQ442495, 99%; *S. lusitanus*, AB184424, 99%.

Sequence accession no. (16S rRNA gene): AY999757.

12. **Streptomyces albiaxialis** Kuznetsov, Zajtseva, Vakulenko and Flippova 1993, 398[VP] (Effective publication: Kuznetsov, Zajtseva, Vakulenko and Flippova 1992, 90.)

al.bi.a.xi.a'lis. L. adj. *albus -a -um* white; L. n. *axis* axle; N.L. adj. *axialis -is -e* axial; N.L. masc. adj. *albiaxialis* white axial.

Forms spiral sporophores with 3–8 extended spirals; sporophores are distributed on a long axis as pseudowhorls. Spores are oblong with a smooth envelope. On solid growth media, the culture forms a white aerial mycelium and dark cream-colored substrate mycelium. The population of *S. albiaxialis* consists of three spontaneous variants: basic, faded, and oligosporous. Basic variant: colonies are slightly bulging, aerial mycelium is white, substrate mycelium is dark cream-colored. Faded variant: colonies are flattened, aerial mycelium is whitish, substrate mycelium is pale yellow. Oligosporous variant: colonies are slightly prominent, whitish aerial mycelium develops only in the center of the colony, substrate mycelium is beige-colored. Soluble pigment is not formed by any variant. It is interesting to note that a population of newly isolated culture originally was absolutely homogeneous and the above-mentioned variants were identified in the population of *Streptomyces albiaxialis* only after cultivation for 7–8 months under laboratory conditions. Probably, this is due to the specific and stable inhabitance conditions of the organism in highly mineralized abyssal (2000 m) stratal water.

The organism liquefies gelatin, coagulates and peptonizes milk, and weakly hydrolyzes starch. It assimilates glucose, sucrose, rhamnose, arabinose, and xylose as a sole carbon source, but rather weakly utilizes raffinose and does not assimilate mannitol or inositol. It assimilates oil hydrocarbons, wax, and Vaseline oil. It is halotolerant and thermotolerant and is able to develop in media containing from 3 to 30% NaCl. The temperature optimum for development is between 28 and 33°C; maximum at 48–50°C. The cell wall contains LL-A_2pm and no differentiating sugars (Type I cell wall). The organism inhibits growth of Gram-stain-positive bacteria, acid-fast mycobacteria, and actinomycetes. It has a slight effect on the growth of some mycelial fungi (*Helminthosporium sativum*), but does not inhibit growth of Gram-stain-negative bacteria and yeasts. The culture is sensitive to monomycin, streptomycin, kanamycin, neomycin, sisomycin, gentamicin, lincomycin, erythromycin, oleandomycin, ristomycin, levomycin, and fusidin, but is resistant to penicillin, carbenicillin, methicillin, polymyxin, tetracycline, and oxytetracycline.

Type strain shows no sequence similarity over 99%.

DNA G+C content (mol%): not known.

Type strain: DSM 41799, NBRC 101002, VKM A-691, NRRL B-24327.

Sequence accession no. (16S rRNA gene): AY999901.

13. **Streptomyces albidochromogenes** Preobrazhenskaya 1986, 573[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

al.bi.do.chro.mo'ge.nes. L. adj. *albidus -a -um*, white; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce), producing; N.L. part. adj. *albidochromogenes* producing white color.

Spore chains are spiral. Spore surface is smooth. On mineral agar 1, glycerol-nitrate agar: aerial mycelium is whitish, creamy, yellow, grayish yellow; substrate mycelium is gray brownish yellow, yellow-gray-brown; no diffusible pigment. On starch-ammonia agar, glycerol-asparagine agar, oatmeal agar: aerial mycelium is white-yellow, yellow; substrate mycelium is colorless or yellow; no diffusible pigment. On organic agar 2: substrate mycelium is absent or whitish, grayish yellow; substrate mycelium and diffusible pigment are gray-brown. Melanoid pigment is found. Grows on glucose, fructose, xylose, arabinose, mannitol, and sucrose; no growth on rhamnose, raffinose, or inositol. Antibiotic is not produced.

Type strain shows the highest sequence similarity to: *S. flavidovirens*, AB184270, 100%; *S. chryseus*, AY999787, 99.9%; *S. helvaticus*, AB184367, 99.9%; *S. enissocaesilis*, AB249930, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 41800, INA 11792, JCM 13858, NBRC 101003.

Sequence accession no. (16S rRNA gene): AB249953.

Further comments: the name of the individual to be credited for *Streptomyces albidochromogenes* proposed in reference Gause et al. (1983) was supplied by T.P. Preobrazhenskaya in a personal communication to the Associate Editor, IJSB.

Culture was originally described as *Actinomyces albidus invertens* Kudrina 1957.

14. **Streptomyces albidoflavus** (Rossi Doria 1891) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 949[AL] ["*Streptotrix albidoflava*" (*sic*) Rossi Doria 1891, 407; "*Streptothrix albidoflava*" Rossi Doria 1891, 407; "*Actinomyces albidoflavus*" Gasperini 1894, 87; "*Cladothrix albido-flava*" (*sic*) Macé 1901, 1095]

al.bi.do.fla'vus. L. adj. *albidus* white; L. adj. *flavus* yellow; N.L. masc. adj. *albidoflavus* whitish yellow.

Spore chains in Section *Rectiflexibiles*. Two of three observers were unable to find sporulating aerial mycelium. Mature spore chains, when formed, are generally short with 3–10 spores per chain. Sporulating aerial mycelium is sometimes found on yeast-malt agar and glycerol-asparagine agar, but is not seen on oatmeal agar or salts-starch agar. Spore surface is smooth. Special morphological characteristics are as follows: substrate mycelium fragments, forming conidia-like or irregular spores; and unusually large spores may sometimes be formed by fragmentation of aerial hyphae.

Color of colony: aerial mass color in the White or Gray color series on yeast-malt agar. Sporulating aerial mycelium is not produced on other ISP media. Reverse side of colony with no distinctive pigments (light yellow to grayish yellow or orange yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth with sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. hydrogenans*, AB184868, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. canescens*, AB184117, 100%; *S. sampsonii*, D63871, 99.9%; *S. koyangensis*, AY079156, 99.7%.

Sequence accession no. (16S rRNA gene): AJ391812.

16. **Streptomyces albireticuli** (Nakazawa 1955) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces albireticuli*" Nakazawa 1955, 248; "*Verticillomyces albireticuli*" Shinobu 1965; *Streptoverticillium albireticuli* Locci, Baldacci and Petrolini Baldan 1969, 59).

al.bi.re.ti′cu.li. L. adj. *albus* white; L. n. *reticulum* a small net; N.L. gen. n. *albireticuli* of a small white net.

Spore chains in Section *Verticillati*. Both monoverticillate and umbellate moverticillate (biverticillate) sporophores are found. Mature spore chains generally have 10–50 spores per chain on suitable media. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar after 2–3 weeks; poor growth of aerial mycelium is seen on glycerol-asparagine agar and variable aerial growth is observed on oatmeal agar and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or White color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tyrosine agar. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and iso-inositol are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose. Variable reports on growth with D-fructose.

Type strain shows the highest sequence similarity to: *S. eurocidicus*, AY999790, 99.8%; *S. biverticillatus*, AJ781381, 99.5%; *S. werraensis*, DQ442558, 99.5%; *S. blastmyceticus*, AY999802, 99.3%; *S. stramineus*, AB184720, 99%; *S. netropsis*, AB184848, 99%; *S. hiroshimensis*, AB184789, 99%.

Type strain: AS 4.1649, ATCC 19721, CBS 460.68, BCRC 12427, CECT 3253, DSM 40051, HUT 6040, IFM 1068, NBRC 12737, NBRC 3400, JCM 4562, JCM 4116, KCTC 9685, NCIMB 9600, NRRL B-1670, NRRL B-5493, NRRL-ISP 5051, RIA 1002, UNIQEM 209.

Sequence accession no. (16S rRNA gene): AB184881.

Further comments: in violation of Rule 33c, in Validation List no. 38, *Streptomyces albireticuli* is proposed as a *nomen revictum* (basonym: "*Streptomyces albireticuli*" Nakazawa 1955).

According to Hatano et al. (2003), *Streptomyces albireticuli* (Nakazawa 1955) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces eurocidicus* (Okami et al. 1954) Witt and Stackebrandt 1991.

17. **Streptomyces albofaciens** Thirumalachar and Bhatt 1960, 63[AL]

al.bo.fa′ci.ens. L. adj. *albus* white; L. v. *facio* make; N.L. part adj. *albofaciens* making white.

Spore chain morphology in Section *Spirales*. Open irregular spirals sometimes appear to arise from an axial

hypha, but true whorls typical of verticillate cultures are not formed. Mature spore chains generally have 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar and glycerol-asparagine agar; White or Gray color series on oatmeal agar and inorganic salts-starch agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only trace of yellow pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only traces of growth on rhamnose. Utilization of sucrose and D-xylose is doubtful.

Type strain shows the highest sequence similarity to: *S. rimosus* subsp. *paromomycinus*, AJ621610, 99.7%; *S. chrestomyceticus*, AJ621609, 99.7%; *S. erumpens*, AJ621603, 99.1%.

18. **Streptomyces alboflavus** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 954[AL] ("*Actinomyces alboflavus*" Waksman and Curtis 1916, 120)

al.bo.fla′vus. L. adj. *albus* white; L. adj. *flavus* yellow; N.L. masc. adj. *alboflavus* whitish yellow.

Typical aerial mycelium is not formed on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Spore chain morphology, spore surface, and aerial mass color of colony cannot be observed on ISP media. Loss of ability to produce sporulating aerial mycelium was noted in an early description of this culture (Waksman 1919, 90). Early descriptions of the culture describe white or yellowish white aerial mycelium on synthetic agar or Czapek's agar only.

Special morphological characteristics: coremia formation on salts-starch agar and glycerol-asparagine agar was recorded by two observers. This same phenomenon was recorded in the original description on Czapek's agar (Waksman 1916, 120): "…aerial mycelium was found to have a tendency to produce…a mass of hyphae massed together into a rope, and from this rope fine filaments coming out in the shape of side branches. The structure looks like the root of a tree and fine rootlets coming out on the side". One ISP observer found straight spore chains within the coremia on glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow or grayed greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments form weakly in peptone-yeast-iron agar and tryptone-yeast broth, but not on tyrosine agar. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only traces of growth on rhamnose. Utilization of sucrose is doubtful.

Type strain shows the highest sequence similarity to: *S. fulvissimus*, AB184434, 99.3%; *S. flavofungini*, AB184359, 99%; *S. variegatus*, AJ781371, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: IMRU 3008, AS 4.1461, ATCC 12626, ATCC 23874, CBS 613.68, BCRC 13664, CIP 104427, DSM 40045, NBRC 13196, IMET 42936, JCM 4615, KCTC 9674, NRRL B-1273, NRRL B-2373, NRRL-ISP 5045, RIA 1112, VKM Ac-972.

Sequence accession no. (16S rRNA gene): EF178699.

19. **Streptomyces albogriseolus** Benedict, Shotwell, Pridham, Lindenfelser and Haynes 1954, 653[AL]

al.bo.gri.se.o′lus. L. adj. *albus* white; N.L. adj. *griseus* gray; L. masc. suff. *-olus* diminutive ending; N.L. dim. masc. adj. *albogriseolus* white grayish.

Spore chains in Section *Spirales*. Spirals are open. Flexuous or *Retinaculum-Apertum* type spore chains are also common. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but not on glycerol-asparagine agar. Spore surface is warty. Warts are not prominent or regular and some smooth spores may be found.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigments (colorless or yellowish gray on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; grayed yellowish brown or olive brown on yeast-malt agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth, but growth on sucrose is less abundant than on other carbon sources. No growth or only traces of growth on raffinose.

Type strain shows the highest sequence similarity to: *S. viridodiastaticus*, AY999852, 99.8%; *S. coeruleorubidus*, AY999719, 99.4%; *S. bellus*, AB184849, 99.2%; *S. coerulescens*, AY999720, 99.2%; *S. griseorubens*, AB184139, 99.1%; *S. longispororuber*, AB184440, 99.1%; *S. atrovirens*, DQ026672, 99.1%; *S. griseoincarnatus*, AJ781328, 99%; *S. labedae*, AB184704, 99%; *S. ambofaciens*, M27245, 99%; *S. erythrogriseus*, AJ781328, 99%; *S. iakyrus*, AB184877, 99%; *S. lusitanus*, AB184424, 99%.

21. **Streptomyces alboniger** (*sic*) Porter, Hewitt, Hesseltine, Krupka, Lowery, Wallace, Bohonos and Williams 1952, 409[AL]

al.bo.ni′ger. L. adj. *albus* white; L. adj. *niger* black; N.L. adj. *alboniger* whitish black.

Spore chains in Section *Rectiflexibiles.* Mature spore chains generally have 10 to 50 or more spores per chain. This morphology is seen on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; aerial mycelium is poorly developed or absent on yeast-malt agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar, except that transient dark reverse colors ranging from very dark brown to nearly black are sometimes reported on salts-starch agar and glycerol-asparagine agar. Reverse pigment is not a pH indicator.

Color in medium: melanoid pigments not formed (or only a faint brown) in peptone-yeast-iron agar in 2–4 d, but transient dark pigments are reported on various media for older cultures. All observers report dark pigment in salts-starch agar in 7 d. This pigment is not pH-sensitive.

D-Glucose, L-arabinose, iso-inositol, and D-mannitol are utilized for growth. No growth or only trace of growth on sucrose and rhamnose. Variable reports on growth with D-fructose, D-xylose, and raffinose.

Type strain shows the highest sequence similarity to: *S. resistomycificus*, AB184166, 99%.

Sequence accession no. (16S rRNA gene): AY845349.

22. **Streptomyces albospinus** (*sic*) Wang, Hamada, Okami and Umezawa 1966, 217[AL]

al.bo.spi′nus. L. adj. *albus* white; L. adj. *spineus* spiny; N.L. masc. adj. *albospinus* (*sic*) white, spiny, referring to the color of the aerial mycelium and nature of spore wall ornamentation.

Produces spinamycin, a non-polyenic anti-fungal antibiotic. Type strain shows the highest sequence similarity to: *S. sioyaensis*, DQ026654, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: M750-G1 (single isolate), AS 4.1628, ATCC 29808, DSM 41674, NBRC 13846, JCM 3399, KCTC 9664, NRRL B-16926.

Sequence accession no. (16S rRNA gene): AB184527.

23a. **Streptomyces albosporeus subsp. albosporeus** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 954[AL] ("*Actinomyces albosporeus*" Krainsky 1914, 649; "*Nocardia albosporea*" Chalmers and Christopherson 1916, 268)

al.bo.spo′re.us. L. adj. *albus* white; N.L. n. *spora* (from Gr. n. *spora* a seed) a spore; N.L. masc. adj. *albosporeus* white spored.

Very sparse formation of aerial mycelium; forms yellow, red, red-brown, violet, or orange-colored vegetative mycelium on some media. Excellent growth on Czapek's solution agar. Tolerates 10% NaCl, but not 13% or more NaCl. No antimicrobial activity detected; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. violaceus*, AB184315, 100%; *S. roseoviolaceus*, AJ399484, 100%; *S. janthinus*, AB184851, 100%; *S. luteogriseus*, AB184379, 99.5%; *S. lomondensis*, AB184673, 99.3%; *S. hawaiiensis*, AB184143, 99.3%; *S. flavoviridis*, AB184842, 99.3%; *S. pilosus*, AB184161, 99.2%; *S. arenae*, AB249977, 99.2%; *S. africanus*, AY208912, 99.2%; *S. tuirus*, AB184690, 99.2%; *S. bellus*, AB184849, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. massasporeus*, AB184152, 99%; *S. afghaniensis*, AJ399483, 99%; *S. levis*, AB184670, 99%; *S. coerulescens*, AY999720, 99%; *S. parvulus*, AB184326, 99%; *S. coeruleorubidus*, AY999719, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1599, ATCC 15394, ATCC 3003, CCM 3157, DSM 40795, IFM 1163, NBRC 15386, JCM 4135, KCTC 9665, NRRL B-1239, NRRL B-2372, RIA 482, VKM Ac-1818.

Sequence accession no. (16S rRNA gene): AJ781327.

Further comment: Lanoot et al. (2002) are of the opinion that *Streptomyces albosporeus* subsp. *albosporeus* (Krainsky 1914) Waksman and Henrici 1948^AL^ is a later heterotypic synonym of *Streptomyces aurantiacus* (Rossi Doria 1891) Waksman 1953^AL^ emend. Lanoot et al. 2002. The type of the subspecies *Streptomyces albosporeus* subsp. *albosporeus* is automatically the type of *Streptomyces albosporeus* (Krainsky 1914) Waksman and Henrici 1948^AL^. Consequently, if an author agrees with Lanoot et al., *Streptomyces albosporeus* must be considered as a later heterotypic synonym of *Streptomyces aurantiacus.* In expressing that opinion Lanoot et al. have placed the type of *Streptomyces albosporeus* in a different species. In this case, Rule 37a of the *Bacteriological Code* (1990 Revision) applies and the authors should have dealt with the nomenclature and taxonomic position of *Streptomyces albosporeus* subsp. *labilomyceticus* Okami et al. 1963^AL^. Authors who follow the proposal to treat the types of *Streptomyces aurantiacus* and *Streptomyces albosporeus* (including the subspecies *Streptomyces albosporeus* subsp. *albosporeus*) as synonyms are not at liberty to use the name *Streptomyces albosporeus* subsp. *labilomyceticus* and must make a taxonomic proposal for placing this subspecies in another species or subspecies.

23b. **Streptomyces albosporeus subsp. labilomyceticus** Okami, Suzuki and Umezawa 1963, 154^AL^ ["*Streptomyces albosporeus* subsp. *labiolomyceticus*" (*sic*, *lapsus calami*) Okami, Suzuki and Umezawa 1963, 154]

la.bi.lo.my.ce′ti.cus. N.L. n. *labilomycinum* labomycin (name of an unstable antibiotic); L. masc. suff. -*ticus* suffix used with the sense of belonging to; N.L. masc. adj. *labilomyceticus* belonging to labilomycin.

Vegetative mycelium is red, yellow, violet, brown, or orange. Produces labilomycin. Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: A955-Y3, NIHJ 425 (single isolate), AS 4.1618, DSM 41672, NBRC 15387, JCM 3383, KCTC 9666.

Sequence accession no. (16S rRNA gene): AB184638.

Further comment: Lanoot et al. (2002) are of the opinion that *Streptomyces albosporeus* subsp. *albosporeus* (Krainsky 1914) Waksman and Henrici 1948^AL^ is a later heterotypic synonym of *Streptomyces aurantiacus* (Rossi Doria 1891) Waksman 1953^AL^ emend. Lanoot et al. 2002. The type of the subspecies *Streptomyces albosporeus* subsp. *albosporeus* is automatically the type of *Streptomyces albosporeus* (Krainsky 1914) Waksman and Henrici 1948^AL^. In expressing that opinion Lanoot et al. have placed the type of *Streptomyces albosporeus* in a different species. In this case Rule 37a (1) applies and the authors should have dealt with the nomenclature and taxonomic position of *Streptomyces albosporeus* subsp. *labilomyceticus* Okami et al. 1963^AL^. Authors who follow the proposal to treat the types of *Streptomyces aurantiacus* and *Streptomyces albosporeus* (including the subspecies *Streptomyces albosporeus* subsp. *albosporeus*) as synonyms are not at liberty to use the name *Streptomyces albosporeus* subsp. *labilomyceticus* and must make a taxonomic proposal for placing this subspecies in another species or subspecies.

24. **Streptomyces alboverticillatus** (Locci and Schofield 1989) Witt and Stackebrandt 1996, 836^VP^ (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Streptoverticillium alboverticillatus*" (*sic*) Arai 1976; "*Streptoverticillium alboverticillatum*" Locci 1985; *Streptoverticillium alboverticillatum* Locci and Schofield 1989, 2504]

al.bo.ver.ti.cil′la.tus. L. adj. *albus* white; N.L. adj. *verticillatus* forming whorls; N.L. adj. *alboverticillatus* white and forming whorls.

Off-white spore mass. Melanin pigment is not produced. Acid is not produced from ribose. Resistant to cephaloxidine, colistin, and cephamandole. *Aspergillus niger* is not inhibited, whereas *Bacillus subtilis* is inhibited. Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1638, ATCC 29818, DSM 41678, NBRC 13861, JCM 5010.

Sequence accession no. (16S rRNA gene): AY999766.

Further comment: according to Hatano et al. (2003), *Streptomyces alboverticillatus* (Locci and Schofield 1989) Witt and Stackebrandt 1996 is a later heterotypic synonym of *Streptomyces griseocarneus* (Benedict et al. 1950) Witt and Stackebrandt 1996.

25. **Streptomyces albovinaceus** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 57^AL^ ("*Actinomyces albovinaceus*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 118)

al.bo.vi.na′ce.us. L. adj. *albus* white; L. adj. *vinaceus* of or belonging to wine or grape: N.L. *albovinaceus* white wine or white grape, but probably refers to pink or red-tinged aerial mycelium, vegetative mycelium and diffusible pigments.

Spore chains in Section *Rectiflexibiles.* Forms short spore chains of more than three spores per chain. This morphology with sporulation aerial mycelium is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. sindenensis*, AB184759, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. griseinus*, AB184205, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. fimicarius*, AY999784, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. globisporus* subsp. *globisporus*, EF178686, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. praecox*, AB184293, 99.9%; *S. anulatus*, DQ026637, 99.9%; *S. parvus*, DQ442537, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. californicus*, AB184755, 99.8%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.8%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.8%; *S. cinereorectus*, AB184646, 99.7%; *S. fulvorobeus*, AB184711, 99.7%; *S. microflavus*, DQ445795, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. lipmanii*, AB184148, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. floridae*, AB184656, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.6%; *S. flavogriseus*, AJ494864, 99.6%; *S. flavovirens*, DQ026635, 99.6%; *S. griseolus*, AB184768, 99.6%; *S. nitrosporeus*, EF178680, 99.5%; *S. halstedii*, EF178695, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. atroolivaceus*, AJ781320, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. finlayi*, AY999788, 99.4%; *S. atratus*, DQ026638, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. celluloflavus*, AB184476, 99.3%; *S. yanii*, AB006159, 99.3%; *S. gelaticus*, DQ026636, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. mutomycini*, AB249951, 99.1%; *S. candidus*, DQ026663, 99.1%; *S. cremeus*, AB184124, 99%.

Sequence accession no. (16S rRNA gene): AB184256.

27. **Streptomyces albulus** Routien *in* Pridham and Lyons 1969, 194[AL]

al.bu'lus. L. masc. adj. *albulus* whitish.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10 to 50 or more spores per chain.

This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series (5fe, light grayish reddish brown; 4li, brownish gray; 4ig, light grayish brown) on yeast-malt agar and oatmeal agar; Gray or Red color series on salts-starch agar and glycerol-asparagine agar (nearest tab in the Red color series is 5dc, grayish yellowish pink). Reverse side of colony with no distinctive pigments (pale or grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth with L-arabinose, D-xylose, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. noursei*, AB184678, 100%; *S. yunnanensis*, AF346818, 99.6%.

Source: not known.

DNA G+C content (mol%): not known.

Sequence accession no. (16S rRNA gene): AB024440.

28. **Streptomyces almquistii** (Duché 1934) Pridham, Hesseltine and Benedict 1958, 74[AL] ["*Actinomyces almquisti*" (*sic*) Duché 1934, 278]

alm.quis'ti.i. N.L. gen. masc. n. *almquistii* of Ernst Bernhard Almquist (1852–1946), named for an early investigator of *Actinomycetales.*

Spore chains in Section *Spirales*; many straight to flexuous hyphae or immature spore chains may also be present. Mature spore chains generally have 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to pale grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Reports vary on utilization of L-arabinose and iso-inositol. No growth or only trace of growth with rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. rangoonensis*, AB184295, 100%; *S. gibsonii*, AB184663, 100%; *S. albus* subsp. *albus*, AJ621602, 100%; *S. flocculus*, AB184272, 99.9%.

Source: not known.

Type strain: AS 4.1685, ATCC 25427, ATCC 618, CBS 925.69, BCRC 12098, DSM 40447, HAMBI 50, HUT 6614, NBRC 13015, IMET 43380, JCM 4451, KCTC 9672, NRRL B-1685, NRRL-ISP 5447, RIA 1207.

Sequence accession no. (16S rRNA gene): AB184258.

29. **Streptomyces althioticus** Yamaguchi, Nakayama, Takeda, Tawara, Maeda, Takeuchi and Umezawa 1957, 196[AL]

al.thi.o'ti.cus. N.L. n. *althiomycinum* althiomycin, name of a sulfur-containing antibiotic; L. masc. suff. -*ticus* suffix used with the sense of belonging to; N.L. masc. adj. *althioticus* belonging to althiomycin.

Spore chains in Section *Spirales*, but flexuous sporophores are also common, especially on yeast-malt agar. Mature spore chains generally have 10–50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny, with only minor surface irregularities suggestive of spines or warts.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow, modified to blue-violet or red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse pigment is pH indicator; changes from red or reddish brown to blue or blue-violet by addition of 0.05 M NaOH.

Color in medium: melanoid pigments are not formed or occur only in trace amounts in peptone-yeast-iron agar and tyrosine agar; blue-violet or red pigment (depending upon pH) occurs in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive, becoming blue or blue-violet when tested with 0.05 M NaOH and red when tested with 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on raffinose. Variable reports on growth with sucrose.

Type strain shows the highest sequence similarity to: *S. matensis*, AB184221, 99.8%; *S. griseorubens*, AB184139, 99.4%; *S. labedae*, AB184704, 99.3%; *S. erythrogriseus*, AJ781328, 99.2%; *S. griseoflavus*, AJ781322, 99.2%; *S. variabilis*, DQ442551, 99.2%; *S. griseoincarnatus*, AJ781328, 99.2%; *S. paradoxus*, AB184628, 99.1%.

Sequence accession no. (16S rRNA gene): AY999808.

30. **Streptomyces amakusaensis** Nagatsu, Anzai, Ohkuma and Suzuki 1963, 209[AL]

a.ma.ku.sa.en'sis. N.L. masc. adj. *amakusaensis* of or belonging to Amakusa Island, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales.* Mature spore chains have 10 to 50 or more spores per chain on yeast-malt agar and salts-starch agar. Sporulating aerial mycelium is

poorly developed or absent on oatmeal agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color of mature aerial mycelium is in the Blue color series on salts-starch agar and the Green or Blue color series on yeast-malt agar; younger mycelium may be in the Gray color series. Mature aerial mycelium is usually not formed on oatmeal agar or glycerol-asparagine agar. Reverse side of colony with distinctive pigments (colorless or pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

This culture does not show good growth with any of the carbon sources tested on Pridham and Gottlieb carbon utilization medium. D-Glucose is utilized for growth. No significant growth occurs on D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, or raffinose and only doubtful traces are seen on L-arabinose and sucrose.

Type strain shows the highest sequence similarity to: *S. inusitatus*, AB184445, 99.8%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1462, ATCC 23876, CBS 615.68, DSM 40219, NBRC 12835, JCM 4617, JCM 4167, KCTC 9753, LMG 19350, NRRL B-3351, NRRL-ISP 5219, RIA 1163, VKM Ac-995.

Sequence accession no. (16S rRNA gene): AY999781.

31. **Streptomyces ambofaciens** Pinnert-Sindico 1954, 702[AL]

am.bo.fa′ci.ens. L. adj. *ambo* both; L. part. adj. *faciens* producing; N.L. part. adj. *ambofaciens* producing both, referring to the production of two different antibiotics by the organism.

Spore chains in Section *Spirales*. Open terminal spirals on long spore chains also suggest *Retinaculum-Apertum* type morphology. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although sporulating aerial mycelium is not abundant on glycerol-asparagine agar. Spore surface is smooth to warty; surface irregularities suggesting warts are small.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigments (colorless to grayed yellow) on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. Dark brown, dark blue, or almost black substrate mycelium pigments are found on salts-starch agar. This pigment is not pH-sensitive.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigments may be found in medium in salts-starch agar; no pigment is found in the medium in yeast-malt agar, oatmeal agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on raffinose. Utilization of sucrose is doubtful.

Type strain shows the highest sequence similarity to: *S. collinus*, AB184123, 99.2%; *S. paradoxus*, AB184628, 99.2%; *S. griseoflavus*, AJ781322, 99.2%; *S. lienomycini*, AJ781353, 99.1%; *S. flaveolus*, AB184764, 99.1%; *S. heliomycini*, AB184712, 99.1%; *S. matensis*, AB184221, 99%; *S. griseorubens*, AB184139, 99%; *S. albaduncus*, AY999757, 99%; *S. albogriseolus*, AJ494865, 99%; *S. coelescens*, AF503496, 99%; *S. rubrogriseus*, AB184681, 99%; *S. violaceoruber*, AF503492, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23877, CBS 616.68, BCRC 11857, CECT 3101, DSM 40053, NBRC 12836, JCM 4618, JCM 4204, KCTC 9111, NRRL 2420, NRRL B-2516, NRRL-ISP 5053, RIA 1115.

Sequence accession no. (16S rRNA gene): M27245.

32. **Streptomyces aminophilus** Foster *in* Oswald, Reedy and Randall *in* Hütter 1961, 370[AL]

a.mi.no′phi.lus. N.L. n. *aminum* amine; N.L. masc. adj. *philus* (from Gr. masc. adj. *philos*) loving; N.L. masc. adj. *aminophilus* amine-nitrogen loving.

Spore chains in Section *Spirales*. Mature spore chains have 3–10, or sometimes more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but formation of sporulation aerial mycelium is poor on oatmeal agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; aerial mycelium poorly developed on oatmeal agar. Reverse side of colony with no distinctive pigments (yellow or grayed yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigments, or only traces of yellow pigment, are found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on iso-inositol and rhamnose. Reports vary on utilization of sucrose and raffinose.

For sequence similarity, see type strain of *S. cacaoi* subsp. *cacaoi*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1416, ATCC 13558, ATCC 14961, ATCC 23878, CBS 617.68, BCRC 11858, DSM 40186, NBRC 12837, JCM 4619, JCM 4275, KCTC 9673, LMG 19319, NCIMB 9827, NRRL 2390, NRRL-ISP 5186, RIA 1140, VKM Ac-706.

Sequence accession no. (16S rRNA gene): AB184183.

Further comments: according to Lanoot et al. (2002), *Streptomyces aminophilus* Foster 1961[AL] is a later heterotypic synonym of *Streptomyces cacaoi* subsp. *cacaoi* (Waksman 1932) Waksman and Henrici 1948[AL] emend. Lanoot et al. 2002.

33. **Streptomyces anandii** Batra and Bajaj 1965, 242[AL]

a.nan.di′i. N.L. gen. n. *anandii* of Anand, Gujarat, India, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*, but open loops and flexuous chains are also seen. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. One of

three observers found globose bodies in the aerial mycelium on yeast-malt agar, and coremia formation on oatmeal agar and salts-starch agar.

Color of colony: aerial mass color in the White or Gray (2dc, yellowish gray or 3ge, light grayish yellowish brown) color series on yeast-malt agar and glycerol-asparagine agar; Gray or Red color series (2dc, yellowish gray to 4ec or 5cb, grayish yellowish pink) on oatmeal agar and salts-starch agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow to olive brown or strong brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, tryptone-yeast broth, and Gause's medium no. 2. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, sucrose, and raffinose are utilized for growth. No growth or only traces of growth with rhamnose.

Type strain shows the highest sequence similarity to: *S. geysiriensis*, DQ442501, 99.3%; *S. minutiscleroticus*, EF178696, 99.3%; *S. rochei*, AB184237, 99.2%; *S. ghanaensis*, AY999851, 99.2%; *S. plicatus*, AB184291, 99.2%; *S. vinaceusdrappus*, AY999929, 99.2%; *S. mutabilis*, EF178679, 99.1%; *S. djakartensis*, AB184657, 99.1%; *S. calvus*, AB184329, 99.1%; *S. asterosporus*, AB184706, 99%; *S. tuirus*, AB184690, 99%; *S. virens*, DQ442554, 99%; *S. aureorectus*, AB184710, 99%.

Source: isolated from soil from Anand, Gujarat, India.

DNA G+C content (mol%): not known.

Type strain: ATCC 19388, CBS 739.72, BCRC 11825, DSM 40535, NBRC 13438, JCM 4720, KCTC 9687, NRRL B-12487, NRRL B-3590, NRRL-ISP 5535, RIA 1399, VKM Ac-1920.

Sequence accession no. (16S rRNA gene): AB184402.

34. **Streptomyces anthocyanicus** (Krasil'nikov et al. 1965) Pridham 1970, 7[AL] ("*Actinomyces anthocyanicus*" Krasil'nikov, Sorokina, Alferova and Bezzubenkova 1965, 118)

an.tho.cya'ni.cus. N.L. n. *anthocyaninum* anthocyanin (a water-soluble vacuolar pigments that may appear red, purple, or blue according to pH), L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *anthocyanicus* belonging to anthocyanin, presumably referring to dark blue color.

Spore chains are of typical *Retinaculum-Apertum* type. Blue-colored vegetative mycelium and diffusible pigments are formed on some media. Exhibits slight anti-bacterial activity.

Type strain shows the highest sequence similarity to: *S. tricolor*, AB184687, 100%; *S. violaceoruber*, AF503492, 99.9%; *S. coelescens*, AF503496, 99.9%; *S. rubrogriseus*, AB184681, 99.9%; *S. violaceolatus* AF503497, 99.8%; *S. humiferus*, AF503491, 99.8%; *S. lienomycini*, AJ781353, 99.7%; *S. tendae*, D63873, 99.5%; *S. violaceorubidus*, AJ781374, 99.5%; *S. coelicoflavus*, AB184650, 99.5%; *S. olivaceus*, AB184743, 99.1%; *S. pactum*, AB184398, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1683, ATCC 19821, DSM 41422, NBRC 14892, JCM 5058, KCTC 9755, NRRL B-12341.

Sequence accession no. (16S rRNA gene): AB184631.

35. **Streptomyces antibioticus** (Waksman and Woodruff 1941) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 942[AL] ("*Actinomyces antibioticus*" Waksman and Woodruff 1941, 246)

an.ti.bio'ti.cus. N.L. masc. adj. *antibioticus* (from Gr. prep. *anti* against; Gr. n. *bios* life; L. suff. *-ticus -a -um* suffix of various meanings, but signifying in general made of or belonging to) against life, antibiotic.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are short, often with only 3–10 spores per chain; longer chains are also found. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; mature aerial mycelium poorly developed on oatmeal agar. Reverse side of colony with no distinctive pigments (grayed yellow-brown on yeast-malt agar, grayed yellow or dark grayish greenish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar); substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar, tyrosine agar, and peptone-yeast broth. No pigment or only trace of yellow in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose. Utilization of D-xylose is doubtful.

Type strain shows the highest sequence similarity to: *S. griseoruber*, AB184209, 99.3%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23879, ATCC 8663, CBS 478.48, CBS 659.68, CCM 3159, BCRC 12164, CECT 3225, DSM 40234, NBRC 12838, IMET 40227, JCM 4620, KCTC 9688, LMG 5966, NCIMB 8504, NRRL B-1701, NRRL B-2770, NRRL-ISP 5234, RIA 1174, VKM Ac-964.

Sequence accession no. (16S rRNA gene): AY999776.

36. **Streptomyces antimycoticus** Waksman *in* Breed, Murray and Smith 1957, 799[AL]

an.ti.my.co'ti.cus. N.L. masc. adj. *antimycoticus* (from Gr. prep. *anti* against; Gr. n. *mukês -etis* fungus; L. suff. *-icus -a -um* suffix of various meanings, but signifying in general made of or belonging to), against fungal, antimycotic.

Spore chains in Section *Spirales*; compact clusters of closed spirals on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; mature spore chains of generally 10–50 spores per chain are found on these media. Spore surface is spiny to warty. Surface irregularities on spores are intermediate between very short, thick spines, and warts.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinct pigment (pale grayed yellow or grayed greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Color in medium: melanoid pigments are not produced

on peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. Growth on L-arabinose and D-xylose is generally less abundant than on the other carbon sources.

Type strain shows the highest sequence similarity to: *S. sporoclivatus*, AB249934, 100%; *S. rutgersensis* subsp. *castelarensis*, AY508511, 99.8%; *S. geldanamycininus*, DQ334781, 99.8%; *S. melanosporofaciens*, AJ271887, 99.6%; *S. rhizosphaericus*, AB249941, 99.1%; *S. asiaticus*, AB249947, 99.1%.

Sequence accession no. (16S rRNA gene): AB184185.

37. **Streptomyces anulatus** (Beijerinck 1912) Waksman *in* Waksman and Lechevalier 1953, 40[AL] ["*Actinomyces Streptothrix annulatus*" (*sic*) Beijerinck 1912, 7; "*Actinomyces annulatus*" (*sic*) Beijerinck 1912, 4; "*Streptomyces annulatus*" (*sic*) Waksman *in* Waksman and Lechevalier 1953, 40]

a.nu.la′tus. L. masc. adj. *anulatus* furnished with a ring.

Spore chains in Section *Rectiflexibiles* on oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but open spirals of two to several turns, hooks and loops of small diameter, as well as straight and flexuous chains are found on yeast-malt agar. The strain as observed on yeast-malt agar can therefore be placed in Section *Spirales* or *Retinaculum-Apertum* type. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Observers selected color tab 2ba (pale yellow) from the Yellow color series and tab a (white) from the White color series; both yellow and white may be observed on the same medium. Reverse side of colony with no distinctive pigments (colorless to pale yellow; grayish yellow or yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment (or only a trace of yellow) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with iso-inositol, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. fimicarius*, AY999784, 100%; *S. badius*, AY999783, 100%; *S. sindenensis*, AB184759, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. griseinus*, AB184205, 100%; *S. acrimycini*, AY999889, 100%; *S. flavofuscus*, AB249935, 100%; *S. mediolani*, AB184674, 100%; *S. praecox*, AB184293, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. griseoplanus*, AY999894, 100%; *S. alboviridis*, AB184256, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. albovinaceus*, AB249958, 99.9%; *S. globisporus* subsp. *globisporus*, EF178686, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. fulvorobeus*, AB184711, 99.9%; *S. microflavus*, DQ445795, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. parvus*, DQ442537, 99.8%; *S. californicus*, AB184755, 99.8%; *S. baarnensis*, EF178688, 99.8%; *S. halstedii*, EF178695, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. floridae*, AB184656, 99.7%; *S. flavogriseus*, AJ494864, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. atroolivaceus*, AJ781320, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. clavifer*, DQ026670, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. yanii*, AB006159, 99.4%; *S. gelaticus*, DQ026636, 99.3%; *S. mutomycini*, AB249951, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. celluloflavus*, AB184476, 99.3%; *S. spiroverticillatus*, AB184814, 99.2%; *S. candidus*, DQ026663, 99.1%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.1%; *S. mauvecolor*, AB184532, 99%; *S. cremeus*, AB184124, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1421, ATCC 27416, CBS 100.18, CBS 670.72, DSM 40361, NBRC 13369, IMET 43334, JCM 4721, KCTC 9756, LMG 19301, NRRL B-2000, NRRL-ISP 5361, RIA 1330, VKM Ac-728.

Sequence accession no. (16S rRNA gene): DQ026637.

Further comments: according to Lanoot et al. (2005b), *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953[AL] emend. Lanoot et al. 2005b is an earlier heterotypic synonym of *Streptomyces chrysomallus* subsp. *chrysomallus* Lindenbein 1952[AL], an earlier heterotypic synonym of *Streptomyces citreofluorescens* (Korenyako et al. 1960) Pridham 1970[AL], and an earlier heterotypic synonym of *Streptomyces fluorescens* (Krasil'nikov 1958) Pridham 1970[AL].

38. **Streptomyces arabicus** Shibata, Nakazawa, Miyake, Inoue and Okabori 1957, 36[AL]

a.ra′bi.cus. L. masc. adj. *arabicus* of or belonging to Arabia, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales* on oatmeal agar and salts-starch agar. Short spore chains on yeast-malt agar and glycerol-asparagine agar may appear to be *Rectiflexibiles* morphology or may show only incomplete spirals or hooks. Mature spore chains on oatmeal agar and salts-starch agar generally have 10 to 50 or more spores per chain; shorter spore chains are found on yeast-malt agar and glycerol-asparagine agar. Spore surface is warty to spiny. Surface irregularities are short and blunt; smooth spores may also be found.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar; Red color series on glycerol-asparagine agar. Observers selected color tabs representing neutral grays to light grayish reddish brown (5fe) for the Gray color series and grayish yellowish pink (5dc) from the Red color series for glycerol-asparagine agar. Reverse side of colony is grayish yellowish brown on

yeast-malt agar; colorless to pale yellowish gray or brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigment is not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Trace of yellow pigment may be found in the medium in oatmeal agar and salts-starch agar or may be absent. This pigment is not pH-sensitive.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on raffinose. Utilization of sucrose is doubtful.

No detailed sequence information is available (only partial sequence).

Source: soil from Arabia.

DNA G+C content (mol%): not known.

Type strain: ATCC 23881, CBS 661.68, DSM 40252, HAMBI 995, HUT 6041, IFM 1118, NBRC 12840, NBRC 14035, NBRC 3406, JCM 4622, JCM 4161, NRRL B-1733, NRRL-ISP 5252, RIA 1178, RIA 512, VKM Ac-1754.

Sequence accession no. (16S rRNA gene): D44271.

Further comments: according to Lanoot et al. (2004), *Streptomyces arabicus* Shibata et al. 1957[AL] is a later heterotypic synonym of *Streptomyces vinaceus* Jones 1952[AL].

39. **Streptomyces ardus** (DeBoer et al. 1961) Witt and Stackebrandt 1996, 836[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces ardus*" DeBoer, Dietz, Lummis and Savage 1961; *Streptoverticillium ardum* Locci, Baldacci and Petrolini Baldan 1969, 59)

ar′dus. L. masc. adj. *ardus* dry, withered, shrunk up, shrivelled, meagre.

Sporulating aerial mycelium is usually absent or very poorly developed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Sterile aerial hyphae are straight or flexuous. Coremia may be produced on yeast-malt agar and oatmeal agar in 7–14 d. The original description reported that this strain sporulates with difficulty, producing only a few monoverticillate and biverticillate sporophores.

Color of colony: aerial mass color of sporulating aerial mycelium not observed. Sterile hyphae or scant aerial mycelia appear to be white to light gray when produced on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale grayish yellow to light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not on tyrosine agar or Gause's medium no. 2. No pigment is found in the medium in oatmeal agar, salts-starch agar, or glycerol-asparagine agar. One observer reports traces of red pigment in yeast-malt agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, iso-Inositol, and D-fructose are utilized for growth. Reports vary on utilization of L-arabinose. No growth or only traces of growth with D-xylose, D-mannitol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. blastmyceticus*, AY999802, 99.4%; *S. hiroshimensis*, AB184789, 99.2%; *S. cinnamoneus*, AB184850, 99.1%; *S. caeruleus*, EF178675, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.167, ATCC 27417, CBS 731.72, BCRC 12319, CECT 3254, DSM 40527, NBRC 13430, JCM 4722, JCM 4543, RIA 1391, NRRL 2817, NRRL-ISP 5527, VKM Ac-930.

Sequence accession no. (16S rRNA gene): AB184864.

Further comments: according to Hatano et al. (2003), *Streptomyces ardus* (DeBoer et al. 1961) Witt and Stackebrandt 1991 is a heterotypic synonym of "*Streptomyces caespitosus*" (NBRC 13490).

40. **Streptomyces arenae** Pridham, Hesseltine and Benedict 1958, 67[AL]

a.re′na.e. L. n. *arena* sand; L. gen. n. *arenae* of sand, referring to a sandy area near Zion, Illinois, USA, from which the organism was isolated.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red or Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Observers selected color tabs 5fe (light grayish reddish brown) from the Gray color wheel and 5cb or 5dc (grayish yellowish pink) from the red color series. One observer selected tab 11ec from the Violet color series as nearest matching color for sporulating aerial growth on salts-starch agar, oatmeal agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale yellow to yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment may be found in yeast-malt agar, oatmeal agar, and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. hawaiiensis*, AB184143, 99.7%; *S. luteogriseus*, AB184379, 99.4%; *S. massasporeus*, AB184152, 99.4%; *S. purpurascens*, AJ399486, 99.3%; *S. violaceus*, AB184315, 99.2%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.2%; *S. janthinus*, AB184851, 99.2%; *S. roseoviolaceus*, AJ399484, 99.2%; *S. flavoviridis*, AB184842, 99%; *S. bellus*, AB184849, 99%; *S. indiaensis*, AB184553, 99%; *S. pilosus*, AB184161, 99%.

Source: the type strain was isolated from a sandy area near Zion, Illinois, USA.

DNA G+C content (mol%): not known.

Type strain: AS 4.1610, ATCC 25428, CBS 926.69, BCRC 11827, DSM 40293, NBRC 13016, JCM 4452, NRRL 2377, NRRL-ISP 5293, RIA 1208, VKM Ac-1201.

Sequence accession no. (16S rRNA gene): AB249977.

41. **Streptomyces argenteolus** Tresner, Davies and Backus 1961, 74^{AL}

ar.gen.te′o.lus. L. masc. adj. *argenteolus* of silver.

Spore chains in Section *Spirales*. This culture is described as "not forming loops or spirals" in the original descriptions appearing in the patents cited above. However, the type strain was observed to produce spirals in subsequent studies by Pridham et al. (1958) and Tresner et al. (1961). Mature spore chains generally have 10 to 50 or more spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is colorless to grayish yellowish green or gray on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed on peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. cinereorectus*, AB184646, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.9%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.9%; *S. microflavus*, DQ445795, 99.8%; *S. griseoplanus*, AY999894, 99.8%; *S. cyaneofuscatus*, AB184860, 99.8%; *S. praecox*, AB184293, 99.8%; *S. anulatus*, DQ026637, 99.8%; *S. fimicarius*, AY999784, 99.8%; *S. flavofuscus*, AB249935, 99.8%; *S. griseolus*, AB184768, 99.8%; *S. alboviridis*, AB184256, 99.8%; *S. lipmanii*, AB184148, 99.8%; *S. fulvorobeus*, AB184711, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. sindenensis*, AB184759, 99.7%; *S. floridae*, AB184656, 99.7%; *S. globisporus* subsp. *globisporus*, EF178686, 99.7%; *S. acrimycini*, AY999889, 99.7%; *S. pluricolorescens*, DQ442540, 99.7%; *S. mediolani*, AB184674, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. griseinus*, AB184205, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. badius*, AY999783, 99.7%; *S. rubiginosohelvolus*, AB184240, 99.7%; *S. californicus*, AB184755, 99.6%; *S. flavogriseus*, AJ494864, 99.6%; *S. parvus*, DQ442537, 99.6%; *S. pulveraceus*, AB184806, 99.5%; *S. yanii*, AB006159, 99.4%; *S. nitrosporeus*, EF178680, 99.4%; *S. olivoviridis*, AB184227, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. atroolivaceus*, AJ781320, 99.3%; *S. bacillaris*, AB184439, 99.3%; *S. finlayi*, AY999788, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. gelaticus*, DQ026636, 99.2%; *S. atratus*, DQ026638, 99.2%; *S. celluloflavus*, AB184476, 99.1%; *S. cremeus*, AB184124, 99.1%; *S. spiroverticillatus*, AB184814, 99.1%; *S. griseobrunneus*, AB249912, 99.1%; *S. albolongus*, AB184425, 99.1%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99%; *S. mutomycini*, AB249951, 99%.

Type strain: AS 4.1693, ATCC 11009, ATCC 23882, CBS 662.68, BCRC 11815, DSM 40226, NBRC 12841, IMET 43659, JCM 4623, JCM 4229, KCTC 1742, LMG 5967, NCIMB 9625, NRRL B-1806, NRRL-ISP 5226, RIA 1168, VKM Ac-747.

Sequence accession no. (16S rRNA gene): AB045872.

Further comments: according to Liu et al. (2005b), *Streptomyces argenteolus* Tresner et al. 1961^{AL} is a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948^{AL} emend. Liu et al. 2005b.

According to Guo et al. (2008), *Streptomyces argenteolus* Tresner et al. 1961^{AL} is not a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948^{AL}.

42. **Streptomyces armeniacus** (Kalakoutskii and Kusnetsov 1964) Wellington and Williams 1981a, 80^{VP} (*Actinoplanes armeniacus* Kalakoutskii and Kusnetsov 1964, 613)

ar.me.ni′a.cus. L. fem. n. *armeniaca* apricot-tree, N.L. masc. adj. *armeniacus* apricot-colored.

Three-week-old cultures show white aerial mycelium and development of spiral spore chains on chitin medium, nutrient agar, oatmeal agar, and ISP 4. On all media, the substrate mycelium is stable and cream-colored to brown. No distinctive pigments are produced in the substrate mycelium or in the medium. According to the original description of *A. armeniacus*, milk is not coagulated or peptonized, gelatin is liquefied, and nitrate is not reduced. The following carbon sources are utilized for growth: L-rhamnose, sorbitol, galactose, D-fructose, D-arabinose, trehalose, cellobiose, esculin, glycerin, and inulin. Growth is weak on glucose, sucrose, lactose, maltose, raffinose, sorbose, xylose, salicin, and dulcitol. No growth occurs on mannitol. Starch is hydrolyzed. Whole-cell hydrolysates contain LL-A_2pm, which is characteristic of cell-wall chemotype I. Susceptible to penicillin, streptomycin, chlortetracycline, erythromycin, and polymyxin; resistant to kanamycin and neomycin.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: 26 A-32, RIA 807, AS 4.1684, ATCC 15676, CBS 559.75, DSM 43125, IFM 1166, IFM 1244, NBRC 12555, IMET 9250, JCM 3070, KCTC 9120, NCIMB 10179, VKM Ac-905.

Sequence accession no. (16S rRNA gene): AB018092.

43. **Streptomyces asiaticus** Sembiring, Ward and Goodfellow 2001, 1619^{VP} (Effective publication: Sembiring, Ward and Goodfellow 2000, 365.)

a.si.a′ti.cus. L. masc. adj. *asiaticus* Asian.

Spore chains are *Spirales*; the spore surface is rugose. On oatmeal agar, the spore mass is gray, the substrate mycelium is grayish-yellow, and the diffusible pigment is yellow. Melanin pigments are not produced. The strain degrades pectin and grows at 45°C.

Type strain shows the highest sequence similarity to: *Streptomyces* sp., AJ391828, 99.5%; *Streptomyces* sp., AJ391831, 99.5%; *S. cangkringensis*, AJ391831, 99.5%; *Streptomyces* sp., AJ391825, 99.4%; *Streptomyces* sp., AJ391826, 99.4%; *Streptomyces* sp., AJ391832, 99.4%; *Streptomyces* sp., A33R1, DSM 41763, AJ391832, 99.4%; *Streptomyces* sp., B23P1, DSM 41765, AJ391825, 99.4%; *Streptomyces* sp., DSM 41768, AJ391826, 99.4%; *Streptomyces* sp., AJ391818, 99.3%; *Streptomyces* sp.,

Type strain shows DNA–DNA similarity to: *S. rhizosphaericus*, AB249941, 100%; *S. cangkringensis*, AJ391831, 99.8%; *S. griseinger*, AJ391818, 99.8%; *S. indonesiensis*, DQ334783, 99.7%; *S. antimycoticus*, AB184185, 99.1%; *S. sporoclivatus*, AB249934, 99.1%; *S. rutgersensis* subsp. *castelarensis*, AY508511, 99.1%; *S. geldanamycininus*, DQ334781, 99%.

Source: isolated from the rhizosphere of the tropical legume *Paraserianthes falcataria*.

DNA G+C content (mol%): not known.

Type strain: A14P1, DSM 41761, JCM 11443, NBRC 100774, NCIMB 13675.

Sequence accession no. (16S rRNA gene): AB249947.

44. **Streptomyces asterosporus** (*ex* Krasil'nikov 1970b) Preobrazhenskaya 1986, 573^{VP} (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces asterosporus*" Krasil'nikov (1970b)

as.te.ro.spo′rus. L. n. *aster*-eris a star; N.L. n. *spora* (from. Gr. n. *spora* seed) spore; N.L. masc. adj. *asterosporus* star-shaped spore.

The type strain, INMI 16^{T}, easily loses its ability to construct aerial mycelium. Spore chains *Spirales*; spores are spiny, of medium-size, and with wide bodies. On mineral agar 1: aerial mycelium is gray, sometimes black, depending on moisture and release; substrate mycelium is colorless, sometimes gray; no diffusible pigment. On glycerol-nitrate agar and oatmeal agar: aerial mycelium is gray; substrate mycelium is colorless or gray; no diffusible pigment. On starch-ammonia agar: aerial mycelium is gray; substrate mycelium is colorless to creamy yellowish; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is poor, gray; substrate mycelium is colorless; no diffusible pigment. On organic agar 2: aerial mycelium is absent or gray; substrate mycelium is colorless or gray; no diffusible pigment. Melanoid pigments are not formed. Grows on glucose, fructose, sucrose, arabinose, galactose, rhamnose, and mannitol; no growth on raffinose or xylose.

Type strain shows the highest sequence similarity to: *S. aureorectus*, AB184710, 100%; *S. calvus*, AB184329, 100%; *S. virens*, DQ442554, 99.8%; *S. minutiscleroticus*, EF178696, 99.1%; *S. geysiriensis*, DQ442501, 99.1%; *S. djakartensis*, AB184657, 99.1%; *S. mutabilis*, EF178679, 99%; *S. rochei*, AB184237, 99%; *S. plicatus*, AB184291, 99%; *S. anandii*, AB184402, 99%; *S. vinaceusdrappus*, AY999929, 99%; *S. tuirus*, AB184690, 99%; *S. ghanaensis*, AY999851, 99%.

Sequence accession no. (16S rRNA gene): AB184706.

45. **Streptomyces atratus** Shibata, Higashide, Yamamoto and Nakazawa 1962, 232^{AL}

a.tra′tus. L. masc. adj. *atratus* clothed in black.

Spore chains of atypical *Retinaculum-Apertum* type. Forms gray to black vegetative mycelium on some media. Probably grows poorly on Czapek's solution agar. Produces rufomycin A, rufomycin B, and other anti-bacterial activity.

Type strain shows the highest sequence similarity to: *S. sanglieri*, AB249945, 100%; *S. yanii*, AB006159, 99.8%; *S. pulveraceus*, AB184806, 99.7%; *S. gelaticus*, DQ026636, 99.6%; *S. badius*, AY999783, 99.3%; *S. pluricolorescens*, DQ442540, 99.3%; *S. sindenensis*, AB184759, 99.3%; *S. albovinaceus*, AB249958, 99.3%; *S. globisporus* subsp. *globisporus*, EF178686, 99.3%; *S. griseinus*, AB184205, 99.3%; *S. flavofuscus*, AB249935, 99.3%; *S. mediolani*, AB184674, 99.3%; *S. fimicarius*, AY999784, 99.3%; *S. anulatus*, DQ026637, 99.3%; *S. rubiginosohelvolus*, AB184240, 99.3%; *S. praecox*, AB184293, 99.3%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.2%; *S. argenteolus*, AB045872, 99.2%; *S. parvus*, DQ442537, 99.2%; *S. cinereorectus*, AB184646, 99.2%; *S. griseoplanus*, AY999894, 99.2%; *S. californicus*, AB184755, 99.2%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.2%; *S. alboviridis*, AB184256, 99.1%; *S. griseolus*, AB184768, 99.1%; *S. baarnensis*, EF178688, 99.1%; *S. griseus* subsp. *griseus*, AY207604, 99.1%; *S. lipmanii*, AB184148, 99.1%; *S. cyaneofuscatus*, AB184860, 99.1%; *S. fulvorobeus*, AB184711, 99.1%; *S. halstedii*, EF178695, 99.1%; *S. acrimycini*, AY999889, 99.1%; *S. flavogriseus*, AJ494864, 99.1%; *S. flavovirens*, DQ026635, 99.1%; *S. microflavus*, DQ445795, 99.1%; *S. floridae*, AB184656, 99.1%; *S. luridiscabiei*, AF361784, 99%; *S. nitrosporeus*, EF178680, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1632, ATCC 14046, DSM 41673, NBRC 3897, JCM 3386, NRRL B-16927.

Sequence accession no. (16S rRNA gene): DQ026638.

46. **Streptomyces atroaurantiacus** Nakagaito, Shimazu, Yokota and Hasegawa 1993a, 624^{VP} (Effective publication: Nakagaito, Shimazu, Yokota and Hasegawa 1992a, 632.)

a.tro.au.ran.ti.a′cus. L. adj. *ater -tra -trum* black, dark; N.L. adj. *aurantiacus -a -um* orange; N.L. masc. adj. *atroaurantiacus* dark orange.

Mature spore chains are long and straight to slightly flexuous. Spores are cylindrical with a smooth surface. Melanoid pigments are produced on tyrosine agar. Brown soluble pigments are produced on yeast extract-malt extract agar and yellow pigments are produced on oatmeal agar. The color of vegetative mycelia is dark orange to slightly orange. The color of aerial mycelia is white. Aerial mycelia are formed slightly on yeast extract-malt extract agar, oatmeal agar, inorganic salts-starch agar, tyrosine agar, Bennett's agar, and water agar. The temperature range for growth is 10–37°C. The concentration of NaCl at which growth occurs is less than 2%. Nitrate is not reduced, starch is hydrolyzed, gelatin is not liquefied, and milk is peptonized and coagulated. D-Glucose, D-arabinose, D-fructose, sucrose, and D-xylose are utilized, but D-mannitol, rhamnose, raffinose, and isoinositol are not utilized or are poorly utilized. The cell wall contains both LL- and *meso*-A_2pm and glycine. Galactose and

a trace of madurose are detected as whole-cell sugars. The phospholipid pattern is type II. MK-9(H_6) and MK-9(H_8) are detected.

Type strain shows no sequence similarity over 99% to other *Streptomyces* species. Type strain shows the highest sequence similarity to following *Kitasatospora*: *Kitasatospora gansuensis*, AY442265, 99.4%.

Source: not known.

DNA G+C content (mol%): 70.2.

Type strain: ATCC 51343, DSM 41649, NBRC 14327, JCM 3337, NRRL B-24282.

Sequence accession no. (16S rRNA gene): DQ026645.

47. **Streptomyces atroolivaceus** (Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 68[AL] ("*Actinomyces atroolivaceus*" Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 143)

at.ro.o.li.va′ce.us. L. adj. *ater -tra -trum* black, dark; N.L. adj. *olivaceus* olive colored; N.L. masc. adj. *atroolivaceus* of a dark olive color, referring to the pigment on an organic medium.

Spore chains in Section *Rectiflexibiles.* Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, and rhamnose are utilized for growth. Variable reports on growth with sucrose, iso-inositol, D-mannitol, and raffinose. Two collaborators reported difficulty in observing results because of poor growth on all carbon sources with Pridham and Gottlieb basal medium.

Type strain shows the highest sequence similarity to: *S. clavifer*, DQ026670, 100%; *S. olivoviridis*, AB184227, 100%; *S. finlayi*, AY999788, 99.7%; *S. mutomycini*, AB249951, 99.7%; *S. pluricolorescens*, DQ442540, 99.5%; *S. sindenensis*, AB184759, 99.5%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.5%; *S. mediolani*, AB184674, 99.5%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.5%; *S. flavofuscus*, AB249935, 99.5%; *S. griseoplanus*, AY999894, 99.5%; *S. anulatus*, DQ026637, 99.5%; *S. praecox*, AB184293, 99.5%; *S. fimicarius*, AY999784, 99.5%; *S. rubiginosohelvolus*, AB184240, 99.5%; *S. badius*, AY999783, 99.5%; *S. griseinus*, AB184205, 99.5%; *S. acrimycini*, AY999889, 99.4%; *S. albovinaceus*, AB249958, 99.4%; *S. globisporus* subsp. *globisporus*, EF178686, 99.4%; *S. alboviridis*, AB184256, 99.4%; *S. cinereorectus*, AB184646, 99.4%; *S. baarnensis*, EF178688, 99.4%; *S. microflavus*, DQ445795, 99.4%; *S. cyaneofuscatus*, AB184860, 99.4%; *S. lipmanii*, AB184148, 99.4%; *S. fulvorobeus*, AB184711, 99.4%; *S. parvus*, DQ442537, 99.3%; *S. floridae*, AB184656, 99.3%; *S. luridiscabiei*, AF361784, 99.3%; *S. griseolus*, AB184768, 99.3%; *S. flavovirens*, DQ026635, 99.3%; *S. argenteolus*, AB045872, 99.3%; *S. californicus*, AB184755, 99.3%; *S. halstedii*, EF178695, 99.2%; *S. griseus* subsp. *griseus*, AY207604, 99.2%; *S. flavogriseus*, AJ494864, 99.2%; *S. candidus*, DQ026663, 99.1%; *S. pulveraceus*, AB184806, 99%; *S. nitrosporeus*, EF178680, 99%; *S. bacillaris*, AB184439, 99%.

48. **Streptomyces atrovirens** (*ex* Preobrazhenskaya et al. 1971) Preobrazhenskaya and Terekhova 1986, 573[VP] (Effective publication: Preobrazhenskaya and Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces atrovirens*" Preobrazhenskaya et al. 1971)

a.tro.vi′rens. L. adj. *ater -tra -trum* black, dark; L. part. adj. *virens* being green; N.L. part. adj. *atrovirens* dark green.

Spore chains in *Spirales*; spore surface is covered with long hair. On mineral agar 1, glycerol-nitrate agar, oatmeal agar, starch ammonia agar, and glycerol-asparagine agar: aerial mycelium is gray; substrate mycelium is grayish green, blue green to dark green; diffusible pigment is pale blue green, grayish green. For several strains, colorless substrate mycelium on some media is possible. On organic agar 2: aerial mycelium is gray; substrate mycelium and diffusible pigment are dark green blue to dark green, black green. The strain builds blue-green color at low pH and red-violet to gray-brownish color at high pH. Melanoid pigments are not formed. Sucrose, mannitol, rhamnose, xylose, and inositol are utilized for growth; weak growth is seen on fructose and raffinose; no growth on arabinose. Produces antibiotic no. 300 (antimetabolite Leycin).

Type strain shows the highest sequence similarity to: *S. heliomycini*, AB184712, 99.2%; *S. viridodiastaticus*, AY999852, 99.1%; *S. flavoviridis*, AB184842, 99.1%; *S. albogriseolus*, AJ494865, 99.1%; *S. coeruleorubidus*, AY999719, 99%; *S. pilosus*, AB184161, 99%.

au.ran.ti.a′cus. N.L. n. *aurantium* generic name of the orange; N.L. masc. adj. *aurantiacus* orange colored.

Spore chains in Section *Spirales.* Short spore chains of 3 to 10 or more spores per chain form irregular hooks and

loops of small diameter and imperfect spirals of one to three turns. Sporulating aerial mycelium is often absent or poorly developed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Fragmenting substrate mycelium may be seen after 12–14 d on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer also notes irregular terminal swellings on some substrate hyphae as well as the presence of subglobose to clavate bodies 5–8 µm in diameter.

Color of colony: aerial mycelium is generally poorly developed or absent on ISP media. When adequate sporulating aerial mycelium is produced, it is in the Red color series (5cb or 6ec, grayish yellowish pink) in yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony is yellow to yellow brown and modified by red to reddish brown on yeast-malt agar and salts-starch agar and to grayish yellowish pink or reddish orange on oatmeal agar and glycerol-asparagine agar. The substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Two of three observers also record utilization of D-xylose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. glomeroaurantiacus*, AB249983, 100%; *S. tauricus*, AB045879, 99%.

Type strain: AS 4.1429, ATCC 19822, ATCC 25429, CBS 927.69, DSM 40412, NBRC 13017, INMI 1373, JCM 4453, LMG 19358, NRRL-ISP 5412, RIA 1209, VKM Ac-44.

Sequence accession no. (16S rRNA gene): AJ781383.

Further comment: Streptomyces aurantiacus (Rossi Doria 1891) Waksman 1953[AL] emend. Lanoot et al. 2002 is an earlier heterotypic synonym of *Streptomyces albosporeus* subsp. *albosporeus* (Krainsky 1914) Waksman and Henrici 1948[AL].

50. **Streptomyces aurantiogriseus** (Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces aurantiogriseus*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 74)

au.ran.tio.gri′se.us. N.L. n. *Aurantium* generic name of the orange; N.L. adj. *griseus* gray; N.L. masc. adj. *aurantiogriseus* orange, gray.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Spirals are open and often are irregular and poorly developed. Long spore chains of the *Retinaculum-Apertum* type and flexuous chains are common. Mature spore chains may be slow to develop; they are moderately long with more than 10 spores per chain on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color is in both the Red and the Gray color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; both colors may appear on the same medium. One observer noted an increase in gray aerial color between 14 and 21 d on glycerol-asparagine agar; this tendency to change from red to gray was also included in the original description. The color tabs most frequently were 2ec (yellowish gray) from the Gray color series and 5ge (light grayish reddish brown) from the Red color series. Reverse side of colony with no distinctive pigment (grayed yellow on oatmeal agar and glycerol-asparagine agar to orange-yellow or brown on yeast-malt and salts-starch agar). Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids are not found in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. coelicolor*, DQ442496, 99.9%; *S. griseoviridis*, AY999807, 99.3%.

51. **Streptomyces auratus** Goodfellow, Kumar, Labeda and Sembiring 2008, 1[VP] (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 198.)

au.ra′tus. L. masc. adj. *auratus* gold colored.

Spore chains are *Spirales*; spore surface is smooth. On oatmeal agar, the aerial spore mass color is gray and the substrate mycelium grayish-yellow; an orange diffusible pigment is produced, but not melanin pigments. The organism produces hydrogen sulfide and degrades adenine, arbutin, chitin, hypoxanthine, Tweens 40, 60 and 80, uric acid, and xanthine, but not casein, guanine, tyrosine, or xylan. It does not reduce nitrate or hydrolyze esculin or urea. Butan-1,4-diol, cellobiose, citric acid, dextrin, D-fructose, L-fucose, D-galactose, D-glucose, *myo*-inositol, maltose, D-mannitol, D-mannose, melezitose, methanol, propanol, pyruvic acid, raffinose, L-rhamnose, D-ribose, L-salicin, and sucrose are used as sole carbon sources, but not α-lactose. α- and L-Alanine, L-aminobutyric acid, L-glutamic acid, L-glycine, L-histidine, L-proline, L-serine, and L-threonine are used as sole carbon and nitrogen sources, but not aspartic acid, L-leucine, DL-methionine, DL-norleucine, L-phenylalanine, L-tryptophan, or L-valine. Grows from pH 5 to 10, at 25 and 37°C, but not at 10 or 40°C. Growth occurs in the presence of 13% (w/v) NaCl. Resistant to carbenicillin, cefoxitin, cephaloridine, chlortetracycline hydrochloride, doxycycline hydrochloride, rifampin, and novobiocin, but sensitive to cefoxitin, cephaloridine, doxycycline hydrochloride, fusidic acid, lincomycin hydrochloride, and oleandomycin phosphate.

Type strain shows the highest sequence similarity to: *S. sioyaensis*, DQ026654, 99%.

Source: not known.
DNA G+C content (mol%): 65.6.
Type strain: DSM 41897, NRRL 8097.
Sequence accession no. (16S rRNA gene): AJ391816.

52. **Streptomyces aureocirculatus** (Krasil'nikov and Yuan *in* Krasil'nikov 1965) Pridham 1970, 8[AL] ("*Actinomyces aureocirculatus*" Krasil'nikov and Yuan *in* Krasil'nikov 1965, 33)

au.re.o.cir.cu.la'tus. L. adj. *aureus* golden; L. part. adj. *circulatus* made circular or round; N.L. masc. adj. *aureocirculatus* golden-curled.

Spore chains in Section *Rectiflexibiles* with some irregular hooks and loops or imperfect spirals. Mature spore chains, when present, are generally long, sometimes with more than 50 spores per chain. Aerial mycelium is poorly developed on all ISP media. Mature spore chains may be found on yeast-malt agar, oatmeal agar, and salts-starch agar. One observer records fragmentation of substrate mycelium on glycerol-asparagine agar at 21 d. Another observer notes the presence of globular bodies and sclerotia on yeast-malt agar, oatmeal agar, and salts-starch agar and conidia-like spores on the substrate mycelium on salts-starch agar at 7 d. Spore surface is smooth.

Color of colony: sporulating aerial mycelium is inadequate for determination of aerial mass color on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The scant aerial mycelium that develops on yeast-malt agar, oatmeal agar, and salts-starch agar is in the White color series. Reverse side of colony with no distinctive pigments (pale yellow to light grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, D-xylose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. Reports vary on utilization of L-arabinose, rhamnose, sucrose, and raffinose. Only one of three observers records utilization of rhamnose and raffinose.

Type strain shows the highest sequence similarity to: *S. novaecaesareae*, AB184357, 99.5%; *S. galilaeus*, AB045878, 99.5%; *S. bobili*, AB249925, 99.4%; *S. pseudovenezuelae*, AB184233, 99.1%; *S. resistomycificus*, AB184166, 99.1%; *S. phaeoluteigriseus*, AJ391815, 99%; *S. chartreusis*, AB184839, 99%.

Source: not known.
DNA G+C content (mol%): not known.
Type strain: AS 4.1609, ATCC 15851, ATCC 19823, ATCC 25430, CBS 928.69, DSM 40386, NBRC 13018, INMI 735, JCM 4454, NRRL B-3324, NRRL-ISP 5386, RIA 1210, RIA 682.
Sequence accession no. (16S rRNA gene): AB184260.

53. **Streptomyces aureofaciens** Duggar 1948, 177[AL]

au.re.o.fa'ci.ens. L. adj. *aureus* golden; L. part. adj. *faciens* producing; N.L. part adj. *aureofaciens* golden-producing, referring pigment produced.

Spore chains in Section *Retinaculiaperti* but chains representative of Section *Rectiflexibiles* are also common. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayed yellow, orange-yellow, or brown on yeast-malt agar, and grayed yellow or greenish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar). Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, and D-fructose are utilized for growth. No growth or only trace of growth on iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. psammoticus*, AY999862, 99.6%; *S. avellaneus*, AB184413, 99.5%; *S. xanthocidicus*, AY999858, 99.1%.

Source: not known.
DNA G+C content (mol%): not known.
Type strain: ATCC 10762, ATCC 23884, CBS 434.51, CBS 664.68, CCM 3239, BCRC 11610, CECT 3206, CIP 57.11, DSM 40127, HAMBI 313, HAMBI 1072, HUT 6048, HUT 6097, ICMP 499, IFM 1042, IFM 1218, IFM 1219, NBRC 12594, NBRC 12843, IMET 43577, JCM 4624, JCM 4008, KACC 20180, LMG 5968, NCAIM B.01479, NCIMB 8234, NRRL 2209, NRRL B-2183, NRRL B-2657, NRRL B-5404, NRRL-ISP 5127, RIA 1129, RIA 57, VKM Ac-771.
Sequence accession no. (16S rRNA gene): AY207608.

54. **Streptomyces aureorectus** (*ex* Taig, Solovieva and Braginskaya 1969) Taig and Solovieva 1986, 573[VP] (Effective publication: Taig and Solovieva *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces aureorectus*" Taig, Solovieva and Braginskaya 1969)

au.re.o.rec'tus. L. adj. *aureus* golden; L. adj. *rectus* straight; N.L. masc. adj. *aureorectus* golden, straight.

Spore chains are straight, spores are smooth. On mineral agar 1 and glycerol-nitrate agar: aerial mycelium is white gray, substrate mycelium is lemon yellow, yellow, dark yellow; diffusible pigment is light yellow, yellow. On starch-ammonia agar (ISP 4): no aerial mycelium; colorless substrate mycelium; no diffusible pigment. On organic agar 2: no aerial mycelium; colorless substrate mycelium; no diffusible pigment. On glycerol-asparagine agar (ISP 5): white aerial mycelium; substrate mycelium and diffusible pigment are yellow. Melanoid pigments are not formed. Good digestion of xylose, galactose, maltose, and raffinose. Antibiotic aurenin is formed.

Type strain shows the highest sequence similarity to: *S. asterosporus*, AB184706, 100%; *S. calvus*, AB184329, 99.9%; *S. virens*, DQ442554, 99.9%; *S. minutiscleroticus*, EF178696, 99%; *S. geysiriensis*, DQ442501, 99%; *S. djakartensis*, AB184657, 99%; *S. anandii*, AB184402, 99%; *S. tuirus*, AB184690, 99%.

Source: not known.
DNA G+C content (mol%): not known.

Type strain: 2843-10, DSM 41692, NBRC 15896, INA A-78, JCM 9947, RIA 553, VKM Ac-1828.

Sequence accession no. (16S rRNA gene): AB184710.

55. **Streptomyces aureoversilis** corrig. (Locci, Baldacci and Petrolini Baldan 1969) Witt and Stackebrandt 1996, 836[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium aureoversile* corrig. Locci, Baldacci and Petrolini Baldan 1969, 59)

au.re.o.ver′si.lis. L. adj. *aureus* golden; L. adj. *versilis* that may be turned, movable; N.L. masc. adj. *aureoversilis* golden, movable.

On potato-glucose agar (Baldacci et al., 1954) and Oxoid nutrient agar, reverse colors are brown; traces of whitish aerial mycelium on potato-glucose agar (Baldacci et al., 1954), more abundant on Oxoid nutrient agar. Growth is fair on Bacto Czapek agar and Casamino acids Czapek agar (1 g/l Difco vitamin-free Casamino acids, replacing sodium nitrate), the reverse being dirty pinkish.

On Casamino acids Czapek agar (1 g/l Difco vitamin-free Casamino acids, replacing sodium nitrate), glucose-asparagine agar (ISP medium 5 with 1% glucose replacing glycerol), glycerol-asparagine agar (ISP medium 5), inorganic salts-starch agar (ISP medium 4), and yeast extract-malt extract agar (ISP medium 2), aerial mycelium is pinkish. On inorganic salts-starch agar (ISP medium 4) and glucose-asparagine agar (ISP medium 5 with 1% glucose replacing glycerol), reverse color is red.

Grows equally well at 27 and 37°C; aerial mycelium production slightly less at 37°C and slow in appearing. The reference strain produces tetraene 380 and pentaene 380 and exhibits anti-bacterial activity.

Type strain shows the highest sequence similarity to: *S. hiroshimensis*, AB184789, 99.5%; *S. cinnamoneus*, AB184850, 99.2%; *S. pseudoechinosporeus*, AB184100, 99.1%; *S. caeruleus*, EF178675, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1641, ATCC 15853, ATCC 25433, CBS 664.69, BCRC 12451, DSM 40387, NBRC 13021, INMI 380, JCM 4457, NRRL B-3325, NRRL-ISP 5387, RIA 1213, RIA 681, VKM Ac-884.

Sequence accession no. (16S rRNA gene): AB184855.

Further comments: according to Hatano et al. (2003), *Streptomyces aureoversilis* corrig. (Locci et al. 1969) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

56. **Streptomyces aureoverticillatus** (Krasil′nikov and Yuan 1960) Pridham 1970, 54[AL] ("*Actinomyces aureoverticillatus*" Krasil′nikov and Yuan 1960, 487)

au.re.o.ver.ti.cil.la′tus. L. adj. *aureus* golden; N.L. adj. *verticillatus* whorled; N.L. adj. *aureoverticillatus* golden, whorled (referring to color of the vegetative mycelium of the organism and nature of its morphology).

Spore chains in Section *Retinaculiaperti* but spore chains representative of Section *Rectiflexibiles* are common. Pseudoverticillate sporophores (suggesting Section *Verticillati*) are found, especially on salts-starch agar. Verticils are not evenly spaced on an enlarged axial hypha as in true verticillate forms. Mature spore chains generally have10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but aerial mycelium is not abundant on yeast-malt agar or oatmeal agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on salts-starch agar and glycerol-asparagine agar (White is also found on these media and poorly sporulated surface on yeast-malt agar). Reverse side of colony is grayed yellow and modified to red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate pigment is a pH indicator; it changes from orange to yellow by addition of 0.05 M NaOH, and from orange to red with HCl.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only trace of growth on rhamnose. Variable reports on growth with sucrose.

Type strain shows the highest sequence similarity to: *S. diastaticus* subsp. *diastaticus*, AB184785, 99%; *S. gougerotii*, AB184742, 99%; *S. intermedius*, AB184277, 99%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 99%.

Sequence accession no. (16S rRNA gene): AY999774.

57. **Streptomyces aureus** Manfio, Atalan, Zakrzewska-Czerwinska, Mordarski, Rodriguez, Collins and Goodfellow 2003b, 1219[VP] (Effective publication: Manfio, Atalan, Zakrzewska-Czerwinska, Mordarski, Rodriguez, Collins and Goodfellow 2003a, 254.)

au′re.us. L. masc. adj. *aureus* golden, referring to the color of the diffusible pigment on oatmeal agar.

Forms extensively branched substrate and aerial hyphae. Open looped chains of smooth-surfaced spores are evident on aerial hyphae. Aerial spore mass is gray; a reddish-orange colored substrate mycelium is formed on Bennett's, glycerol-asparagine, inorganic salts-starch, oatmeal, and yeast extract-malt extract agars. A golden colored diffusible pigment is produced on oatmeal agar. Hippurate is hydrolyzed and hypoxanthine and xanthine are degraded. Cleaves L-citrulline-7-amino-methylcoumarin (7AMC), L-phenylalanine-7AMC (endopeptidase substrates), L-cysteine-7AMC, L-glutamine-7AMC, L-ornithine-7AMC, L-proline-7AMC (exopeptidase substrates), and 4-methylumbelliferone (4MU)-elaidate (organic ester), but not methoxysuccinyl-L-alanine (endopeptidase substrate), L-pyroglutamate-7AMC (exopeptidase substrate), 4MU-β-D-galactopyranoside, 4MU-*N*-acetyl-β-D-glucosaminide, 4MU-α-D-glucoside, 4MU-2-deoxy-β-D-glucopyranoside, 4MU-β-D-xyloside (glycosides), or 4MU-pyrophosphate (inorganic ester). *myo*-Inositol, inulin, D(+)mannitol, citrate, and pyruvate are used as sole carbon sources for energy and growth but not dextran. L-Hydroxyproline is used as a sole carbon and nitrogen source, but not histidine. Grows between 10 and 35°C and in the

presence of thallous acetate (0.001%, w/v), but does not show antimicrobial activity against *Bacillus subtilis* NCIMB 3610, *Candida albicans* CBS 562, *Micrococcus luteus* NCIMB 196, or *Streptomyces murinus* ISP 5091.

Type strain shows the highest sequence similarity to: *S. durmitorensis*, DQ067287, 99.6%; *S. kanamyceticus*, DQ442511, 99.5%.

Source: not known.

DNA G+C content (mol%): 67.0–73.0.

Type strain: B7319, DSM 41785, JCM 12605, NBRC 100912, NCIMB 13927.

Sequence accession no. (16S rRNA gene): AB249976.

58. **Streptomyces avellaneus** Baldacci and Grein 1966, 195[AL]

a.vel.la′ne.us. N.L. masc. adj. *avellaneus* (from L. n. *avellana* hazel) hazel colored, referring to color of the aerial mycelium of the organism.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray; 3fe, light brownish gray; or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (strong yellowish brown to dark brown on yeast-malt agar; grayish yellow to orange yellow, light brown, or strong brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-fructose, and sucrose are utilized for growth. No growth or only traces of growth with L-arabinose, D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. psammoticus*, AY999862, 100%; *S. aureofaciens*, AY207608, 99.5%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.2%; *S. purpureus*, AJ781324, 99.2%; *S. aburaviensis*, AY999779, 99%.

Sequence accession no. (16S rRNA gene): AB184413.

59. **Streptomyces avermectinius** Takahashi, Matsumoto, Seino, Ueno, Iwai and Ōmura 2002, 2167[VP]

a.ver.mec.ti′ni.us. N.L. adj. *avermectinius* pertaining to avermectin, an antibiotic produced by the organism.

Forms spiral spore chains. Spores are oval in shape (0.8 × 1.2 µm) and have a smooth surface. Soluble pigment is produced. Vegetative mycelia are brown. Aerial mass color is gray. Melanin and H_2S production, hydrolysis of starch and casein, liquefaction of gelatin, and peptonization of milk are positive. Adenine, casein, hypoxanthine and xanthine are decomposed but not cellulose. Grows in the presence of 5% (w/v) NaCl, but is sensitive to streptomycin (20 µg/ml) and novobiocin (20 µg/ml). Arabinose, fructose, glucose, inositol, lactose, maltose, mannitol, mannose, raffinose, rhamnose, sucrose, and xylose are decomposed.

For sequence similarity, see type strain of *Streptomyces avermitilis*. Type strain shows DNA–DNA similarity to: *S. bottropensis* DSM 40262^T, 15%; *S. cinnabarinus* DSM 40467^T, 21%; *S. galbus* DSM 40089^T, 33%; *S. griseochromogenes* DSM 40499^T, 7%; *S. luteogriseus* DSM 40483^T, 22%; *S. mirabilis* DSM 40553^T, 16%; *S. olivochromogenes* DSM 40451^T, 26%; *S. phaeochromogenes* DSM 40073^T, 20%.

DNA G+C content (mol%): 70.3.

Type strain: MA-4680, ATCC 31267, JCM 5070, NCIMB 12804, NRRL 8165.

Sequence accession no. (16S rRNA gene): AB078897.

Further comments: Streptomyces avermectinius Takahashi et al. 2002 is a later homotypic synonym of *Streptomyces avermitilis* (*ex* Burg et al. 1979) Kim and Goodfellow 2002.

60. **Streptomyces avermitilis** (*ex* Burg, Miller, Baker, Birnbaum, Curri, Hartman, Kong, Monaghan, Olson, Putter, Tunac, Wallick, Stapley, Oiwa and Ōmura 1979) Kim and Goodfellow 2002, 2013[VP] ("*Streptomyces avermitilis*" Burg, Miller, Baker, Birnbaum, Curri, Hartman, Kong, Monaghan, Olson, Putter, Tunac, Wallick, Stapley, Oiwa and Ōmura 1979, 363)

a.ver.mi′ti.lis. N.L. masc. adj. *avermitilis* intended to mean avermectin producer.

The spore chains consist of 15 or more spherical to oval-shaped spores with smooth surfaces. Sporulation occurs on standard media such as egg albumin, glycerol-asparagine, inorganic salts-starch, and oatmeal agars. A gray aerial spore mass is formed on oatmeal agar; the colony reverse is dark brown to tan. Melanin pigments are produced on peptone-yeast extract-iron agar and brown diffusible pigments are produced on a range of standard media. Forms an extensively branched substrate mycelium and aerial hyphae that differentiate into long, compact spiral chains which become more open as the culture ages. The culture grows well at 28 and 37°C, but does not grow at 50°C. It metabolizes casein, but not tyrosine. It liquefies gelatin and uses glucose, maltose, mannose, and rhamnose, but not cellulose as sole carbon sources for energy and growth. Avermectins, a family of 16-membered antiparasitic macromolecules, are produced.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. cinnabarinus* DSM 40467^T, 98±7%; *S. griseochromogenes* DSM 40499^T, 99±0%.

Source: isolated from a soil sample collected at Kawana, Ito City, Shizuoka Prefecture, Japan.

DNA G+C content (mol%): not known.

Type strain: MA-4680, ATCC 31267, JCM 5070, NBRC 14893, NCIMB 12804, NRRL 8165.

Sequence accession no. (16S rRNA gene): BA000030.

Further comments: Streptomyces avermitilis (*ex* Burg et al. 1979) Kim and Goodfellow 2002 is an earlier homotypic synonym of *Streptomyces avermectinius* Takahashi et al. 2002.

61. **Streptomyces avidinii** Stapley, Mata, Miller, Demny and Woodruff 1964, 20[AL]

a.vi.di′ni.i. N.L. n. *avidinum* avidin the name of a biotin-binding protein; N.L. gen. n. *avidinii* of avidin.

Produces the antibiotic MSD-235 complex, streptavidin, and antibiotic MSD-235S, a synergistic anti-bacterial complex; poor growth on Czapek's solution agar.

Type strain shows the highest sequence similarity to: *S. nojiriensis*, AJ781355, 99.7%; *S. subrutilus*, X80825, 99.7%; *S. sporoaveus*, AJ781370, 99.7%; *S. xanthophaeus*, DQ442560, 99.7%; *S. goshikiensis*, EF178693, 99.6%; *S. cirratus*, AY999794, 99.6%; *S. vinaceus*, AB184394, 99.6%; *S. sporoverrucosus*, DQ442544, 99.5%; *S. cinnamonensis*, AB184707, 99.5%; *S. colombiensis*, DQ026646, 99.5%; *S. virginiae*, D85119, 99.3%.

Sequence accession no. (16S rRNA gene): AB184395.

62. **Streptomyces azureus** Kelly, Kutscher and Tuoti 1959, 1334[AL]

a.zur′e.us. N.L. masc. adj. *azureus* azure-blue, referring to the color of the aerial mycelium of the organism.

Spore chains in Section *Spirales*. Some sporophores supporting spiral spore chains appear to arise singly, in pairs, or in simple or branched whorls along an axial hypha (suggesting verticillate morphology) especially on salts-starch agar and glycerol-asparagine agar. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Blue color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar, tyrosine agar and tryptone-yeast extract broth. Pigments (other than melanoids) not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. capillispiralis*, AB184577, 99.5%; *S. gancidicus*, AB184660, 99.5%; *S. pseudogriseolus*, DQ442541, 99.5%; *S. caelestis*, X80824, 99.5%; *S. cellulosae*, DQ442495, 99.4%; *S. levis*, AB184670, 99.4%; *S. paradoxus*, AB184628, 99.3%; *S. djakartensis*, AB184657, 99.2%; *S. coerulescens*, AY999720, 99.2%; *S. tuirus*, AB184690, 99.2%; *S. bellus*, AB184849, 99.2%; *S. carpinensis*, AB184574, 99.1%; *S. minutiscleroticus*, EF178696, 99.1%; *S. africanus*, AY208912, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. geysiriensis*, DQ442501, 99.1%; *S. afghaniensis*, AJ399483, 99%; *S. rochei*, AB184237, 99%; *S. plicatus*, AB184291, 99%; *S. vinaceusdrappus*, AY999929, 99%; *S. matensis*, AB184221, 99%; *S. ghanaensis*, AY999851, 99%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1675, ATCC 14921, ATCC 19728, CBS 467.68, BCRC 12479, DSM 40106, NBRC 12744, IMET 43765, JCM 4564, NRRL B-2655, NRRL-ISP 5106, PCM 2313, RIA 1009, UNIQEM 122, VKM Ac-719.

Sequence accession no. (16S rRNA gene): EF178674.

63. **Streptomyces baarnensis** Pridham, Hesseltine and Benedict 1958, 74[AL]

ba.arn.en′sis. N.L. masc. adj. *baarnensis* of or belonging to Baarn, a community in the Netherlands province of Utrecht.

This strain has apparently lost the ability to produce good sporulating aerial mycelium. Spore chains, when found, are straight (Section *Rectiflexibiles*) and usually contain more than 10 spores per chain. Spore surface is smooth.

Color of colony: aerial mycelium on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar is inadequate for determination of aerial mass color. The original description of Duché (op. cit) describes early appearance of abundant greenish aerial mycelium on comparable media. Reverse side of colony with no distinctive pigment; yellow-brown on yeast-malt agar, light grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on raffinose. Utilization of sucrose is doubtful.

Type strain shows the highest sequence similarity to: *S. griseoplanus*, AY999894, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. praecox*, AB184293, 99.9%; *S. pluricolorescens*, DQ442540, 99.8%; *S. sindenensis*, AB184759, 99.8%; *S. anulatus*, DQ026637, 99.8%; *S. griseinus*, AB184205, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. badius*, AY999783, 99.8%; *S. mediolani*, AB184674, 99.8%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.8%; *S. rubiginosohelvolus*, AB184240, 99.8%; *S. lipmanii*, AB184148, 99.7%; *S. fulvorobeus*, AB184711, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. microflavus*, DQ445795, 99.7%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. parvus*, DQ442537, 99.7%; *S. globisporus* subsp. *globisporus*, EF178686, 99.7%; *S. cinereorectus*, AB184646, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. californicus*, AB184755, 99.7%; *S. griseolus*, AB184768, 99.6%; *S. griseus* subsp. *griseus*, AY207604, 99.6%; *S. floridae*, AB184656, 99.6%; *S. flavovirens*, DQ026635, 99.5%; *S. halstedii*, EF178695, 99.5%; *S. atroolivaceus*, AJ781320, 99.4%; *S. finlayi*, AY999788, 99.4%; *S. flavogriseus*, AJ494864, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. pulveraceus*, AB184806, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. clavifer*, DQ026670, 99.3%; *S. yanii*, AB006159, 99.3%; *S. nitrosporeus*, EF178680, 99.3%; *S. albolongus*,

DNA G+C content (mol%): not known.

Type strain: AS 4.1406, ATCC 19729, ATCC 19888, CBS 468.68, BCRC 13759, DSM 40139, HAMBI 1008, NBRC 12745, IMET 43089, INA 1203/53, JCM 4350, LMG 19353, NCIMB 13011, NRRL B-2567, NRRL-ISP 5139, RIA 1010, VKM Ac-735.

Sequence accession no. (16S rRNA gene): AY999783.

66. **Streptomyces baldaccii** corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium baldaccii* Farina and Locci 1966, 48)

bal.dac′ci.i. N.L. gen. masc. n. *baldacii* of Baldacci (named for Elio Baldacci (1909–1987), who introduced the genus *Streptoverticillium*).

On potato-glucose agar (Baldacci et al., 1954): abundant growth; color, reverse is pink to salmon pink and aerial mycelium is pale pink to salmon pink with whitish tufts. On Bacto Czapek agar: limited growth; color, reverse is colorless to pinkish and aerial mycelium is traces of pink. On Casamino acids Czapek agar (1 g/l Difco vitamin-free Casamino acids replacing sodium nitrate): growth slightly better than on Bacto Czapek agar; colors similar. On glucose-asparagine agar (ISP medium 5 with 1% glucose replacing glycerol): good growth; color, reverse is red and aerial mycelium is pale pink with whitish overgrowth. On glycerol-asparagine agar (ISP medium 5): good growth; color, reverse is red and aerial mycelium is pale pink. On inorganic salts-starch agar (ISP medium 4): good growth; color, reverse is red to cherry red and aerial mycelium is pale pink. On yeast extract-malt extract agar (ISP medium 2): good growth; color, reverse is orange-red and aerial mycelium is pink with whitish patches. On Bacto Emerson agar and Bennett agar (1% glucose, 0.1% Bacto beef agar, 0.1% yeast extract, 0.2% peptone, 1.5% agar): good growth; color, reverse is orange-red and aerial mycelium is pink. On Oxoid nutrient agar: good growth; color, reverse is initially orange-red turning to brown-red and aerial mycelium (poor) is pink with violet shades; brown soluble pigment. Optimal growth at 27°C; only substrate mycelium is formed at 37°C; no growth at 45°C. Type strain exhibits anti-bacterial and anti-fungal activity.

No detailed sequence information is available (only partial sequence).

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23654, DSM 40845, HUT 6222, IPV 1339, IPV 174, NBRC 14693, JCM 4272, NRRL B-3500.

Sequence accession no. (16S rRNA gene): X53164.

Further comments: D.P. Labeda proposes *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991, *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991, and *Streptomyces roseoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 as later synonyms of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991. This proposal is in violation of Rule 24b(1) because the senior epithet is *roseoverticillatus*. *Streptomyces baldaccii*, *Streptomyces biverticillatus*, and *Streptomyces fervens* are therefore to be regarded as later synonyms of *Streptomyces roseoverticillatus*.

Hatano et al. (1997) propose *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991 as an earlier heterotypic synonym of *Streptomyces spitsbergensis* Wieczorek et al. (1993).

According to Hatano et al. (2003), *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

67. **Streptomyces bambergiensis** Wallhäusser, Nesemann, Präve and Steigler 1966, 734[AL]

bam.ber.gi.en′sis. N.L. masc. adj. *bambergiensis* of or belonging to Bamberg, Germany, the source of the soil from which the organism was isolated.

Spore chains in Section *Retinaculiaperti* to *Rectiflexibiles*. Strongly flexuous chains with open or primitive spirals and terminal loops or turns. Mature spore chains are moderately long, usually with more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is hairy.

Color of colony: aerial mass color in the Green color series (1½li-ig, light grayish olive or olive gray to 24½ih-li, dark greenish gray or grayish olive green) on yeast-malt agar, oatmeal agar, and salts-starch agar. White, Yellow or Green color series on glycerol-asparagine agar. Reverse side of colony is strong brown on yeast-malt agar; light yellow on oatmeal agar; light grayish olive to olive brown on salts-starch agar; and yellowish pink, orange-yellow, or reddish brown on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Greenish to reddish pigment is reported in the medium in yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. One observer reports no pigments in these media. The pigment, when present, is not pH-sensitive.

D-Glucose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on the utilization of L-arabinose. No growth or only traces of growth with sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. prasinus*, DQ026658, 99.9%; *S. hirsutus*, AB184844, 99.1%; *S. cyanoalbus*, AB184882, 99%.

Source: soil, Bamberg, Germany.

Type strain: AS 4.1439, ATCC 13879, CBS 780.72, CECT 3211, DSM 40590, NBRC 13479, JCM 4728, KCTC 9019, LMG 19299, NRRL B-12101, NRRL B-12521, NRRL-ISP 5590, RIA 1440, VKM Ac-975.

Sequence accession no. (16S rRNA gene): AB184869.

68. **Streptomyces bangladeshensis** Al-Bari, Bhuiyan, Flores, Petrosyan, García-Varela and Ul Islam 2005, 1976[VP]

ban.gla.desh.en′sis. N.L. masc. adj. *bangladeshensis* of or belonging to Bangladesh, the source of the soil from which the organism was isolated.

Forms highly branched substrate mycelium and aerial hyphae that differentiate into long *Rectiflexibiles* chains of 8–10 spores. Aerial spore mass color is yellow-green. Substrate mycelium is beige on standard media. Yellowish diffusible pigments are formed on Czapek–Dox agar. Melanin pigments are not produced on peptone-iron or tyrosine agars. Positive for H_2S production. Utilizes glucose, sucrose, *myo*-inositol, mannitol, mannose, maltose, fructose, L-arabinose, rhamnose, glycerol, raffinose, and trehalose as sole carbon sources. Growth occurs at 20–50°C, at pH 6.0–11.0, and in the presence of 2% (w/v) NaCl, neomycin sulfate (50 µg/ml), and penicillin (10 IU/ml). Produces bis-(2-ethylhexyl)-phthalate, an antimicrobial agent.

Type strain shows the highest sequence similarity to: *S. rameus*, AY999821, 99.8%; *S. glomeratus*, AB249917, 99.2%; *S. achromogenes* subsp. *rubradiris*, AY999846, 99%.

Source: isolated from soil from Bangladesh.

DNA G+C content (mol%): not known.

Type strain: AAB-4, LMG 22738, NRRL B-24326.

Sequence accession no. (16S rRNA gene): AY750056.

69. **Streptomyces beijiangensis** Li, Zhang, Xu, Cui, Lu, Xu and Jiang 2002b, 1698[VP]

bei.ji.ang.en′sis. N.L. masc. adj. *beijiangensis* of or pertaining to Beijiang, a place in Yinjiang province in western China.

Aerial mycelium at maturity forms long chains of spores that are straight to flexuous or occasionally *Retinaculiaperti* and are nonmotile. Aerial mycelium and substrate mycelium are well developed. Good growth on most media. Optimum growth temperature is between 8 and 20°C. Diffusible pigment is not produced. The color of the colonies is medium-dependent. Glucose, galactose, and glycerol are utilized; lactose, mannose, inulin, acetate, and oxalate are not utilized. Positive for nitrate reduction and urease. Diagnostic amino acid of peptidoglycan is *meso*-A_2pm. Whole-cell hydrolysates contain glucose and small quantities of xylose, galactose, and arabinose. The predominant menaquinones are MK-9(H_6) and MK-9(H_8) and phosphatidylethanolamine is the diagnostic phospholipid. Predominant cellular fatty acids are $C_{15:0}$ anteiso, $C_{16:0}$ iso, and $C_{17:0}$ cyclo.

Type strain shows no sequence similarity over 99%.

Source: isolated from soil in low-temperature habitats collected from Beijiang, western China.

DNA G+C content (mol%): not known.

Type strain: YIM6, AS 4.1718, CCTCC 99005, DSM 41794, JCM 11882, NBRC 100044.

Sequence accession no. (16S rRNA gene): AF385681.

70. **Streptomyces bellus** Margalith and Beretta 1960, 193[AL]

bel′lus. L. masc. adj. *bellus* pretty, handsome.

Spore chains in Section *Spirales*. Short spore chains may form incomplete spirals, hooks, and loops of small diameter or flexuous chains. Spirals are best developed on salts-starch agar. Hooks and loops are of small diameter and therefore are not typical of *Retinaculum-Apertum* cultures. Mature spore chains with 3–10, or sometimes more than 10, spores per chain are produced on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Blue color series on oatmeal agar and salts-starch agar; White or Blue color series on yeast-malt agar and glycerol-asparagine agar. Reverse side of colony: substrate color is modified by red (orange) pigment on yeast-malt agar and glycerol-asparagine agar and by red or blue pigments on oatmeal agar and salts-starch agar. These pigments are not pH indicators.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Trace of red pigment may be found in the medium in glycerol-asparagine agar; it is not a pH indicator. Pigments are not found in the medium in yeast-malt agar, oatmeal agar, or salts-starch agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. coerulescens*, AY999720, 100%; *S. coeruleorubidus*, AY999719, 99.6%; *S. lomondensis*, AB184673, 99.4%; *S. purpurascens*, AJ399486, 99.4%; *S. lusitanus*, AB184424, 99.4%; *S. iakyrus*, AB184877, 99.3%; *S. paradoxus*, AB184628, 99.2%; *S. viridodiastaticus*, AY999852, 99.2%; *S. parvulus*, AB184326, 99.2%; *S. matensis*, AB184221, 99.2%; *S. azureus*, EF178674, 99.2%; *S. indiaensis*, AB184553, 99.2%; *S. albogriseolus*, AJ494865, 99.2%; *S. longispororuber*, AB184440, 99.2%; *S. hawaiiensis*, AB184143, 99.2%; *S. violaceus*, AB184315, 99.1%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.1%; *S. janthinus*, AB184851, 99.1%; *S. thermocarboxydus*, U94490, 99.1%; *S. spinoverrucosus*, AB184578, 99.1%; *S. griseorubens*, AB184139, 99.1%; *S. erythrogriseus*, AJ781328, 99%; *S. griseoincarnatus*, AJ781328, 99%; *S. labedae*, AB184704, 99%; *S. variabilis*, DQ442551, 99%; *S. massasporeus*, AB184152, 99%; *S. luteogriseus*, AB184379, 99%; *S. roseoviolaceus*, AJ399484, 99%; *S. arenae*, AB249977, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: A/870, ATCC 14925, ATCC 23886, CBS 666.68, DSM 40185, NBRC 12844, JCM 4292, JCM 4625, NRRL B-2575, NRRL-ISP 5185, RIA 1139.

Sequence accession no. (16S rRNA gene): AB184849.

71. **Streptomyces bikiniensis** Johnstone and Waksman 1947, 294[AL] ("*Actinomyces bikiniensis*" Krasil'nikov 1949, 100)

bi.ki.ni.en′sis. N.L. masc. adj. *bikiniensis* of or pertaining to Bikini Atoll.

Spore chains in Section *Rectiflexibiles* with long, straight to slightly flexuous spore chains of more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs are 3ih, dark gray; 2fe, medium gray; 3fe, light brownish gray; 5fe, light grayish reddish brown; and 2dc, yellowish gray. Reverse side of colony with no distinctive pigments (grayish yellow to yellowish brown or olive brown on yeast-malt agar; pale to grayish yellow or light grayish yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth, but the reaction is weak in tyrosine agar. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-xylose, and D-fructose are utilized for growth. Reports vary on utilization of L-arabinose; utilization of D-mannitol, rhamnose, and raffinose is doubtful and no significant growth is seen with iso-inositol or sucrose.

Type strain shows the highest sequence similarity to: *S. violaceorectus*, AB184314, 99.7%; *S. vietnamensis*, DQ311081, 99.5%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99.3%; *S. tanashiensis*, AJ781362, 99.1%; *S. nashvillensis*, AB184286, 99%; *S. viridobrunneus*, AJ781372, 99%; *S. laurentii*, AJ781342, 99%; *S. showdoensis*, AB184389, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.569, ATCC 11062, CBS 412.54, DSM 40581, HUT 6084, IFM 1057, NBRC 14598, IMET 41362, JCM 4011, KCTC 9172, NRRL B-1049, NRRL B-2690, NRRL-ISP 5581, RIA 471, RIA 74, VKM Ac-999.

Sequence accession no. (16S rRNA gene): X79851.

72. **Streptomyces biverticillatus** (Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Actinomyces biverticillatus*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 75; "*Streptomyces biverticillatus*" Pridham, Hesseltine and Benedict 1958, 72; "*Streptoverticillium biverticillatus*" (*sic*) Baldacci 1958, 25; *Streptoverticillium biverticillatum* Farina and Locci 1966, 49]

bi.ver.ti.cil′la.tus. L. adv. num. *bi*s twice; L. masc. n. *verticillus* whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *biverticillatus* whorled twice.

Spore chains in Section *Verticillati* with umbellate-monoverticillate (biverticillate) spore chains. Mature spore chains generally contain 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (one observer, only, placed this culture in the Violet color series on yeast-malt agar and salts-starch agar). Reverse side of colony is red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is pH-sensitive, changing from red to orange-red with addition of 0.05 M NaOH and from red to violet-red or blue with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in less than 2 d in peptone-yeast-iron agar and tryptone-yeast broth, but more slowly in tyrosine agar. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and possibly iso-inositol and D-fructose are utilized for growth; growth on iso-inositol and D-fructose is much less abundant than on D-glucose. No growth or only trace of growth on L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose. Type strain shows the highest sequence similarity to: *S. werraensis*, DQ442558, 100%; *S. albireticuli*, AB184881, 99.5%; *S. netropsis*, AB184848, 99.3%; *S. eurocidicus*, AY999790, 99.3%; *S. cinnamoneus*, AB184850, 99%; *S. hiroshimensis*, AB184789, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23615, CBS 668.68, NBRC 12845, JCM 4431, NRRL-ISP 5272, RIA 1190.

Sequence accession no. (16S rRNA gene): AJ781381.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces biverticillatus* is proposed as a *nomen revictum* [basonym: "*Streptomyces biverticillatus*" (Preobrazhenskaya and Ryabova 1957) Pridham et al. 1958].

Labeda (1996) proposes *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991, *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991, and *Streptomyces roseoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 as later synonyms of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991. This proposal is in violation of Rule 24b of the *Bacteriological Code* (1990 Revision) because the senior epithet is *roseoverticillatus. Streptomyces baldaccii*, *Streptomyces biverticillatus*, and *Streptomyces fervens* are therefore to be regarded as later synonyms of *Streptomyces roseoverticillatus*.

According to Hatano et al. (2003), *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

73. **Streptomyces blastmyceticus** (Watanabe et al. 1957) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces blastmyceticus*" Watanabe, Tanaka, Fukuhara, Miyairi, Yonehara and Umezawa 1957, 39; *Streptoverticillium blastmyceticum* Locci, Baldacci and Petrolini Baldan 1969, 43)

blast.my.ce′ti.cus. N.L. n. *blastomycinum* blastomycin; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *blastmyceticus* belonging to blastomycin.

Spore chains in Section *Verticillati*. Both monoverticillate and umbellate monoverticillate (biverticillate) spore chains are found. Spore chains are short; usually only 3–10

spores per chain. This morphology is seen on oatmeal agar; mature spore chains may not develop on other ISP media. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on oatmeal agar. Better sporulation and color is produced on tomato paste-oatmeal agar or on Hickey and Tresner's agar. On these media, an olive-gray color (Gray color series) is produced. Immature and poorly sporulated aerial growth on other media may appear to place this species in the Yellow or Red color series. Reverse side of colony is characteristic grayed yellow on yeast-malt agar and grayed greenish yellow to olive-brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast-broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, and D-fructose are utilized for growth. No growth or only trace of growth on D-xylose, rhamnose, and raffinose. Utilization of sucrose and D-mannitol is doubtful.

Type strain shows the highest sequence similarity to: *S. hiroshimensis*, AB184789, 99.5%; *S. ardus*, AB184864, 99.4%; *S. cinnamoneus*, AB184850, 99.3%; *S. albireticuli*, AB184881, 99.3%; *S. eurocidicus*, AY999790, 99.2%; *S. caeruleus*, EF178675, 99.1%; *S. pseudoechinosporeus*, AB184100, 99.1%; *S. abikoensis*, AB184537, 99%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1647, ATCC 19731, CBS 470.68, BCRC 13387, CECT 3257, DSM 40029, NBRC 12747, JCM 4184, JCM 4565, NCIMB 9800, NRRL B-5480, NRRL-ISP 5029, RIA 1012.

Sequence accession no. (16S rRNA gene): AY999802.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces blastmyceticus* is proposed as a *nomen revictum* (basonym: "*Streptomyces blastmyceticus*" Watanabe et al. 1957).

74. **Streptomyces bluensis** Mason, Dietz and Hanka 1963b, 608[AL]

blu.en'sis. N.L. masc. adj. *bluensis* (from French adj. *bleu*) belonging to blue, referring to the blue color of the aerial mycelium.

Spore chains in Section *Spirales*. Spirals may be poorly developed on some media and open loops, imperfect spirals, or flexuous spore chains may be common. Observers do not agree on the best medium for spiral formation. Some spirals are reported by different observers on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore chains are short to long, usually with more than 10 spores per chain. Spore surface is spiny.

Color of colony: aerial mass color in the Blue or White color series on yeast-malt agar; White color series on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tab in the Blue color series is 19dc, pale blue. Reverse side of colony with no distinctive pigments (light grayish yellow to pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1463, ATCC 27420, CBS 239.69, CBS 761.72, DSM 40564, NBRC 13460, JCM 4729, LMG 5969, NCIMB 9754, NRRL 2876, NRRL-ISP 5564, RIA 1421.

Sequence accession no. (16S rRNA gene): X79324.

75. **Streptomyces bobili** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 937[AL] ["*Actinomyces bobili*" Waksman and Curtis 1916, 121; "*Streptomyces bobiliae*" (*sic*) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 937]

bo.bi'li. N.L. gen. n. *bobili* named for Bobili, the nickname of an individual.

Spore chains in Section *Spirales*. Sporulating aerial mycelium is not produced at 27 or 37°C on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar, or on supplementary media (Czapek's agar and potato-glucose agar) used by one observer. Two observers found some spots of sporulating aerial mycelium on salts-starch agar. One collaborator (J.B. Routien) found spiral spore chains with 10 to 30 or more spores per chain on Pridham and Gottlieb's basal salts medium for carbon utilization enriched with xylose, raffinose, or glucose. Incubation was at 37°C. Spirals were most abundant when xylose was carbon source. The first description by Waksman (1916, op. cit) notes the absence of true aerial mycelium or spores on Czapek's medium. The description published in 1919 (Waksman, (1919), op. cit) notes spiral formation on scant white aerial mycelium on glycerin-synthetic agar and traces of aerial mycelium in spots only on starch-agar plates and potato plugs. Aerial mycelium was not produced on the seven other solid media used by Waksman. The present culture seems to conform well to the early descriptions. Spore surface is smooth.

Color of colony: aerial mass color cannot be observed on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Sparse aerial mycelium, when produced, is white. On the reverse side of the colony, substrate mycelium color may be grayish yellow, or may be modified with red to reddish gray or pink, reddish brown, or reddish orange. The substrate mycelium color is dependent on pH, changing from yellowish pink to violet pink with addition of 0.05 M NaOH and from yellowish pink to yellow orange with 0.05 M HCl.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigments are found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only trace of growth on D-mannitol.

Type strain shows the highest sequence similarity to: *S. galilaeus*, AB045878, 100%; *S. phaeoluteigriseus*, AJ391815, 99.5%; *S. resistomycificus*, AB184166, 99.5%; *S. aureocirculatus*, AB184260, 99.4%; *S. novaecaesareae*, AB184357, 99.3%; *S. chartreusis*, AB184839, 99.3%; *S. pseudovenezuelae*, AB184233, 99.2%; *S. prunicolor*, DQ026659, 99%.

Type strain: AS 4.1624, ATCC 23889, ATCC 3310, CBS 419.34, CBS 675.68, BCRC 13671, DSM 40056, HAMBI 1059, NBRC 13199, NBRC 16166, IMET 41372, JCM 4012, JCM 4627, NRRL B-1338, NRRL B-2097, NRRL-ISP 5056, RIA 1116, VKM Ac-1756.

Sequence accession no. (16S rRNA gene): AB249925.

76. **Streptomyces bottropensis** Waksman 1961 182[AL]

bot.trop.en′sis. N.L. masc. adj. *bottropensis* of or pertaining to the German town Bottrop.

Spore chains in Section *Spirales*. Hooks, primitive spirals, and terminal spirals of only one or two turns are common together with open spirals of several turns. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but spirals are best developed on salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is yellow to strong brown, reddish brown, or sometimes very dark brown.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Brown pigment is found in the medium in yeast-malt agar and glycerol-asparagine agar; this pigment is not pH-sensitive.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth, but growth on raffinose is less abundant than on other carbon sources.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1669, ATCC 25435, CBS 163.64, CBS 667.69, BCRC 12063, CIP 105278, DSM 40262, NBRC 13023, JCM 4459, NRRL-ISP 5262, RIA 1215, VKM Ac-1755.

Sequence accession no. (16S rRNA gene): AB026217.

77. **Streptomyces brasiliensis** (Falcão de Morais, Chaves Batista and Massa et al. 1966) Goodfellow, Williams and Alderson 1986a, 573[VP] (Effective publication: Goodfellow, Williams and Alderson 1986c, 53.) (*Elytrosporangium brasiliense* Falcão de Morais, Chaves Batista and Massa 1966, 170)

bra.si.li.en′sis. N.L. masc. adj. *brasiliensis* of or pertaining to Brazil.

Forms extensively branched substrate and aerial mycelium. The latter bears long spiral spore chains, the former bears occasional short chains of spores (0.8–1.0 µm diameter). The spore surface is smooth. The aerial spore mass is gray to greenish gray; the reverse color is colorless to light cream. Does not form melanin pigments. Esculin, casein, guanine, starch, testosterone, and tyrosine are degraded, but allantoin, arbutin, chitin, elastin, hypoxanthine, lecithin, pectin, urea, and xanthine are not. Nitrate is reduced to nitrite and hydrogen sulfide is produced. Adonitol, L-arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, inulin, D-lactose, mannitol, D-mannose, melezitose, melibiose, raffinose, L-rhamnose, salicin, sucrose, trehalose, and D-xylose are used as sole carbon sources, but xylitol is not. Grows on L-arginine, L-cysteine, L-histidine, L-methionine, L-phenylalanine, L-serine, L-threonine, and L-valine, but not on DL-amino-n-butyric acid, L-hydroxyproline, or potassium nitrate, as sole nitrogen sources. Growth occurs at 25–37°C, but not at 10 or 45°C. Tolerant to phenol (0.1%, w/v), sodium azide (0.02%, w/v), and sodium chloride (4%, w/v). Sensitive to rifampin and 7% (w/v) sodium chloride. Does not show antimicrobial activity against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046[T], *Saccharomyces cerevisiae* CBS 1171[T], or *Streptomyces murinus* ISP 5091. The peptidoglycan contains LL-A_2pm as major diamino acid and is of the A3γ type (Stackebrandt et al., 1981). Contains octahydrogenated menaquinones with nine isoprene units as the predominant isoprenolog.

Type strain shows the highest sequence similarity to: *S. africanus*, AY208912, 99.2%; *S. afghaniensis*, AJ399483, 99.1%.

Source: isolated from soil at Alianca, north of Pernambuco, Brazil.

DNA G+C content (mol%): not known.

Type strain: ATCC 23727, CBS 520.68, DSM 43159, IFM 1210, NBRC 12596, KCC A-0086, KCTC 9071, JCM 3086, NBRC 101283, RIA 911, VKM Ac-1310, VKM Ac-656.

Sequence accession no. (16S rRNA gene): AB249981.

78. **Streptomyces bungoensis** Eguchi, Takada, Nakamura, Tanaka, Makino and Oshima 1993, 797[VP]

bun.go.en′sis. N.L. masc. adj. *bungoensis* of or belonging to Bungo, a region of Japan.

Mature spore chains are spiral, with 20 or more spores per chain. Spores are ellipsoidal, 0.5–0.7 µm in diameter. Spore surface is spiny. Mycelia do not fragment into coccoid or bacilliary structures. Aerial mass on glucose-asparagine agar, glycerol-asparagine agar, inorganic salts-starch agar, and oatmeal agar is grayish brown or gray. Reverse sides of colonies are brownish yellow on glucose-asparagine agar and glycerol-asparagine agar, gray on inorganic salts-starch agar and oatmeal agar, yellow on tyrosine agar, and reddish brown on yeast extract-malt extract agar. The melanoid pigment produced is pale brown on tyrosine agar and brownish black on peptone-yeast extract-iron agar and in tryptone-yeast extract broth. A reddish brown soluble pigment is produced on nutrient agar and a brownish black pigment is produced on yeast extract-malt extract agar. No soluble pigment is produced on sucrose-nitrate agar, glucose-asparagine agar, glycerol-asparagine agar, organic salts-starch agar, oatmeal agar, or Czapek's solution agar. Starch is not hydrolyzed, gelatin is liquefied, and milk is peptonized, but not coagulated. D-Glucose, D-fructose, D-galactose, D-xylose, L-arabinose, and D-mannitol are utilized for growth, but rhamnose, iso-inositol, and salicin are not. Little, if any, growth is observed with raffinose and scant growth is observed with sucrose. The cell-wall composition is chemotype I containing LL-A_2pm and glycine, but no galactose, arabinose, or *meso*-A_2pm.

Type strain shows the highest sequence similarity to: *S. longwoodensis*, AB184580, 99.7%; *S. galbus*, X79852, 99.7%; *S. capoamus*, AB045877, 99.5%; *S. corchorusii*, AB184267, 99.4%; *S. olivaceoviridis*, AB184288, 99.3%; *S. canarius*, AB184396, 99.2%.

Source: not known.

DNA G+C content (mol%): 70.3.

Type strain: AS 4.1653, DSM 41781, FERM 8432, NBRC 15711, JCM 9925, MS16-10G.

Sequence accession no. (16S rRNA gene): AB184696.

79a. **Streptomyces cacaoi subsp. cacaoi** (Waksman *in* Bunting 1932) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 951[AL] emend. Lanoot, Vancanneyt, Cleenwerck,Wang, Li, Liu and Swings 2002, 828 ("*Actinomyces cacaoi*" Waksman *in* Bunting 1932, 516)

ca.ca′o.i. Mexican Spanish *cacao* the cacao; N.L. gen. n. *cacaoi* of cacao.

Spore chains in Section *Spirales* and poorly developed on all ISP media. Spirals, when formed, are open. Incomplete spirals, loops, hooks, or even flexuous chains may be common when spore chains are short. These are not typical of the large hooks and loops of *Retinaculum-Apertum* cultures. Mature spore chains may contain 10–50 spores per chain on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar, but long chains are not common. Oatmeal agar is not suitable for observation of morphology or aerial mass color. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed on peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast extract broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on iso-inositol and rhamnose. Utilization of sucrose and raffinose is doubtful.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): 73.0.

Sequence accession no. (16S rRNA gene): DQ026644.

80. **Streptomyces caelestis** DeBoer, Dietz, Wilkins, Lewis and Savage 1955a, 831[AL]

ca.e.les′tis. L. masc. adj. *caelestis* of the sky, heavenly (referring to the blue color of the aerial mycelium and spores).

Spore chains in Section *Spirales* or *Retinaculiaperti*. Spirals are usually poorly developed and show only a few turns; loops and hooks are of small diameter and therefore are not representative of typical *Retinaculum-Apertum* cultures. Short spore chains; usually only 3–10 spores per chain on yeast-malt agar, oatmeal agar, and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Blue color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tyrosine agar. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only trace of growth on D-mannitol. Type strain shows the highest sequence similarity to: *S. azureus*, EF178674, 99.5%; *S. gancidicus*, AB184660, 99.2%; *S. levis*, AB184670, 99.1%; *S. cellulosae*, DQ442495, 99.1%; *S. capillispiralis*, AB184577, 99.1%; *S. pseudogriseolus*, DQ442541, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1688, ATCC 14924, ATCC 15084, ATCC 19733, CBS 472.68, CBS 967.70, BCRC 13685, DSM 40084, NBRC 12749, IMET 43502, SP 5084, JCM 4218, JCM 4566, LMG 5970, NCIMB 9751, NRRL 2418, RIA 1014, VKM Ac-1822.

Sequence accession no. (16S rRNA gene): X80824.

81. **Streptomyces caeruleus** (Baldacci 1944) Pridham, Hesseltine and Benedict 1958, 60[AL] emend. Lanoot, Vancanneyt, Cleenwerck,Wang, Li, Liu and Swings 2002, 828 ("*Actinomyces caeruleus*" Baldacci 1944, 180)

ca.e.ru′le.us. L. masc. adj. *caeruleus* dark blue, azure.

Spore chains in Section *Rectiflexibiles*. Two observers report poor growth or no sporulating aerial mycelium on yeast-malt agar and oatmeal agar. Mature spore chains with more than 10 spores per chain are usually produced on salts-starch agar, glycerol-asparagine agar, and Hickey and

Tresner medium. Typical spores are not observed; atypical spores are smooth. One observer reports fragmentation of substrate mycelium on Hickey and Tresner agar in 14 d.

Color of colony: aerial mass color in the Gray color series on salts-starch agar, glycerol-asparagine agar, and Hickey and Tresner agar. One observer also records gray aerial mycelium on yeast-malt agar and oatmeal agar, but sporulating growth on these media may be inadequate for color determination. Reverse side of colony with a distinct blackish blue to very dark grayish purple pigment on salts-starch agar, glycerol-asparagine agar, and Hickey and Tresner agar. A dark blue violet to blackish pigment may also be seen in yeast-malt agar or glycerol-asparagine agar when adequate growth occurs. Reverse mycelium pigment is a pH indicator, changing from dark violet or blue to deep green with addition of 0.05 M NaOH.

Color in medium: melanoid pigments probably are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth; observation may be obscured by dark violet or blue pigments. Brown violet, blue, or blue black pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, and Hickey and Tresner agar. This pigment may not be pH-sensitive when tested with 0.05 M NaOH or HCl, or may be somewhat sensitive to 0.05 M NaOH, changing from violet to very deep green.

Growth is generally very poor or absent on Pridham and Gottlieb carbon-utilization medium containing D-glucose or other carbon sources. Carbon utilization cannot be determined accurately on this medium. One observer notes that traces of growth on sucrose and rhamnose are probably equal to growth on D-glucose, but this observation is of doubtful significance.

Type strain shows the highest sequence similarity to: *S. hiroshimensis*, AB184789, 99.7%; *S. abikoensis*, AB184537, 99.5%; *S. lilacinus*, AB184819, 99.3%; *S. cinnamoneus*, AB184850, 99.3%; *S. pseudoechinosporeus*, AB184100, 99.2%; *S. sapporonensis*, AB184508, 99.1%; *S. aureoversilis*, AB184855, 99.1%; *S. blastmyceticus*, AY999802, 99.1%; *S. ardus*, AB184864, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27421, CBS 645.72, BCRC 13659, DSM 40103, NBRC 13344, IMET 40622, IPV 930, ISP 5103, JCM 4014, JCM 4730, LMG 19399, NRRL B-1623, NRRL B-2194, NRRL-ISP 5103, RIA 1305, RIA 755, VKM Ac-1918.

Sequence accession no. (16S rRNA gene): EF178675.

Further comments: Streptomyces caeruleus (Baldacci 1944) Pridham et al. 1958 emend. Lanoot et al. 2002 is an earlier heterotypic synonym of *Streptomyces niveus* Smith et al. 1956 and an earlier heterotypic synonym of *Streptomyces spheroides* Wallick et al. 1956.

82. **Streptomyces californicus** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 936[AL] ("*Actinomyces californicus*" Waksman and Curtis 1916, 122)

ca.li.for'ni.cus. N.L. masc. adj. *californicus* of or belonging to California, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer recorded both Gray series and Violet series for aerial color on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This difference may be due to pH. Reverse side of colony is modified by Violet or Red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is a pH indicator and is changed from blue-violet to red by addition of 0.05 M HCl, or from red to blue-violet by addition of NaOH.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar; pigment is found in medium in oatmeal agar and tyrosine-asparagine agar. It is pH-sensitive when tested with 0.05 M NaOH or HCl, showing same change as noted for reverse color.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. floridae*, AB184656, 100%; *S. griseinus*, AB184205, 99.9%; *S. badius*, AY999783, 99.9%; *S. pluricolorescens*, DQ442540, 99.9%; *S. sindenensis*, AB184759, 99.9%; *S. mediolani*, AB184674, 99.9%; *S. rubiginosohelvolus*, AB184240, 99.9%; *S. fulvorobeus*, AB184711, 99.8%; *S. alboviridis*, AB184256, 99.8%; *S. praecox*, AB184293, 99.8%; *S. flavofuscus*, AB249935, 99.8%; *S. griseoplanus*, AY999894, 99.8%; *S. lipmanii*, AB184148, 99.8%; *S. albovinaceus*, AB249958, 99.8%; *S. fimicarius*, AY999784, 99.8%; *S. globisporus* subsp. *globisporus*, EF178686, 99.8%; *S. anulatus*, DQ026637, 99.8%; *S. microflavus*, DQ445795, 99.8%; *S. cinereorectus*, AB184646, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. parvus*, DQ442537, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. acrimycini*, AY999889, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.7%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.7%; *S. argenteolus*, AB045872, 99.6%; *S. finlayi*, AY999788, 99.6%; *S. bacillaris*, AB184439, 99.6%; *S. halstedii*, EF178695, 99.5%; *S. albolongus*, AB184425, 99.5%; *S. griseobrunneus*, AB249912, 99.5%; *S. celluloflavus*, AB184476, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. flavogriseus*, AJ494864, 99.5%; *S. flavovirens*, DQ026635, 99.5%; *S. griseolus*, AB184768, 99.5%; *S. griseus* subsp. *griseus*, AY207604, 99.5%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.4%; *S. nitrosporeus*, EF178680, 99.4%; *S. clavifer*, DQ026670, 99.4%; *S. sanglieri*, AB249945, 99.3%; *S. atroolivaceus*, AJ781320, 99.3%; *S. candidus*, DQ026663, 99.3%; *S. olivoviridis*, AB184227, 99.3%; *S. mutomycini*, AB249951, 99.2%; *S. gelaticus*, DQ026636, 99.2%; *S. yanii*, AB006159, 99.2%; *S. atratus*, DQ026638, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cremeus*, AB184124, 99%.

Sequence accession no. (16S rRNA gene): AB184755.

83. **Streptomyces calvus** Backus, Tresner and Campbell 1957, 533[AL]

cal′vus. L. masc. adj. *calvus* bald, referring to the sparse formation of aerial mycelium of the organism.

Spore chains in Section *Spirales* on salts-starch agar. Spore chains are short and poorly developed or absent on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. The original description by Backus, Tresner and Campbell also indicates that aerial mycelium is poorly developed on most media with best sporulation and spiral development on starch containing inorganic salts media. Spore surface is spiny to hairy.

Color of colony: aerial mycelium is inadequate for color determination on most media. When mature sporulating aerial mycelium is formed on yeast-malt agar or salts-starch agar, it is in the Gray color series. Reverse side of colony with no distinctive pigments; colorless or grayish yellowish brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not found in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. asterosporus*, AB184706, 100%; *S. virens*, DQ442554, 99.9%; *S. aureorectus*, AB184710, 99.9%; *S. djakartensis*, AB184657, 99.2%; *S. minutiscleroticus*, EF178696, 99.1%; *S. tuirus*, AB184690, 99.1%; *S. ghanaensis*, AY999851, 99.1%; *S. geysiriensis*, DQ442501, 99.1%; *S. anandii*, AB184402, 99.1%; *S. plicatus*, AB184291, 99%; *S. pilosus*, AB184161, 99%; *S. vinaceusdrappus*, AY999929, 99%; *S. mutabilis*, EF178679, 99%; *S. graminearus* AJ781333, 99%; *S. griseomycini*, AB184137, 99%; *S. griseostramineus*, AB184140, 99%; *S. flavoviridis*, AB184842, 99%; *S. rochei*, AB184237, 99%.

Type strain: AS 4.1691, ATCC 13382, ATCC 23890, CBS 350.62, CBS 676.68, BCRC 11859, CECT 3271, DSM 40010, IFM 1093, NBRC 13200, JCM 4326, JCM 4628, NCIMB 12240, NRRL B-2399, NRRL-ISP 5010, RIA 1103, VKM Ac-1185.

Sequence accession no. (16S rRNA gene): AB184329.

84. **Streptomyces canarius** Vavra and Dietz 1965, 76[AL]

ca.na′ri.us. L. masc. adj. *canarius* of or belonging to the Canary Islands; intended to refer to production of a bright canary yellow pigment on a variety of media.

Spore chains in Section *Spirales*; straight to flexuous chains are also seen. Mature spore chains are moderately long with more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White to Gray color series (b, white, to 2ge, light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar when adequate sporulating aerial mycelium is produced. Aerial mycelium may be inadequate for color determination on some of these media. Reverse side of colony is distinctive greenish yellow to moderate yellow, orange-yellow or strong yellowish brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow to yellow-green pigment may be found in the medium in oatmeal agar and glycerol-asparagine agar. This pigment is not pH-sensitive.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. olivaceoviridis*, AB184288, 100%; *S. corchorusii*, AB184267, 99.8%; *S. capoamus*, AB045877, 99.5%; *S. longwoodensis*, AB184580, 99.3%; *S. bungoensis*, AB184696, 99.2%; *S. galbus*, X79852, 99.1%.

Type strain: AS 4.1581, ATCC 27423, CBS 732.72, BCRC 11621, DSM 40528, HAMBI 1014, NBRC 13431, IMET 43539, JCM 4549, JCM 4733, NCIMB 9468, NRRL 2976, NRRL-ISP 5528, RIA 1392.

Sequence accession no. (16S rRNA gene): AB184396.

85. **Streptomyces candidus** (*ex* Krasil'nikov 1941) Sveshnikova 1986, 574[VP] (Effective publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces candidus*" Krasil'nikov 1941)

can′di.dus. L. masc. adj. *candidus* shining white, clear, bright.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long and flexuous, often with more than 50 spores per chain. This morphology is seen on salts-starch agar and glycerol-asparagine agar. Sporulation may be poor on yeast-malt agar and oatmeal agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although aerial mycelium may be poorly developed on yeast-malt agar and oatmeal agar. Reverse side of colony with no distinctive pigments (colorless or very pale grayed yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Pigments are not formed in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. albolongus*, AB184425, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. finlayi*, AY999788, 99.3%; *S. spiroverticillatus*, AB184814, 99.3%; *S. floridae*, AB184656, 99.3%; *S. californicus*, AB184755, 99.3%; *S. badius*, AY999783, 99.2%; *S. cremeus*, AB184124, 99.2%;

86. **Streptomyces canescens** Waksman *in* Breed, Murray and Smith 1957, 768[AL] ["*Streptomyces canescus*" (*sic*) Hickey, Corum, Hidy, Cohen, Nager and Kropp 1952, 473]

ca.nes′cens. L. part. adj. *canescens* growing white, whiten.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, or glycerol-asparagine agar; grayed greenish yellow on salts-starch agar; substrate is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar or tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-xylose, and D-mannitol are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, rhamnose and raffinose. Variable reports on growth with D-fructose and L-arabinose.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. hydrogenans*, AB184868, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 99.9%; *S. champavatii*, DQ026642, 99.9%; *S. sampsonii*, D63871, 99.7%; *S. koyangensis*, AY079156, 99.6%.

Sequence accession no. (16S rRNA gene): AB184117.

87. **Streptomyces cangkringensis** Sembiring, Ward and Goodfellow 2001, 1619[VP] (Effective publication: Sembiring, Ward and Goodfellow 2000, 365.)

cang.krin.gen′sis. N.L. masc. adj. *cangkringensis* of or pertaining to Cangkringan, a place in Java, Indonesia.

Spore chains are *Spirales*; spore surface is rugose. On oatmeal agar, the spore mass is gray, the substrate mycelium is grayish-yellow, and the diffusible pigment is yellow. Melanin pigments are not produced. The organism degrades pectin but not adenine and grows at 45°C.

Type strain shows the highest sequence similarity to: *S. rhizosphaericus*, AB249941, 99.8%; *S. asiaticus*, AB249947, 99.8%; *S. indonesiensis*, DQ334783, 99.7%; *S. griseinger*, AJ391818, 99.5%. Type strain shows DNA–DNA similarity to: *S. albiflaviniger* NRRL B-1356^T, 98.4%; *S. geldanamycinus* NRRL 3602^T, 98.9%; *S. griseiniger* NRRL B1865^T, 99.3%; *S. rhizosphaericus* DSM 41760^T, 99.0%; *S. asiaticus* DSM 41761^T, 99.2%; *S. indonesiensis* DSM 41759^T, 98.4%; *S. javensis* DSM 41764^T, 98.4%; *S. yogyakartensis* DSM 41766^T, 98.2%.

Source: isolated from non-rhizosphere soil adjacent to a stand of the tropical legume *Paraserianthes falcataria*.

DNA G+C content (mol%): not known.

Type strain: D13P3, DSM 41769, JCM 11444, NBRC 100775, NCIMB 13684.

Sequence accession no. (16S rRNA gene): AJ391831.

88. **Streptomyces caniferus** (*ex* Krasil'nikov 1970b) Preobrazhenskaya 1986, 574[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces caniferus*" Krasil'nikov 1970b)

ca.ni′fe.rus. L. adj. *canus* white; L. adj. *ferus* (from L. v. *fero* to bear) bearing; N.L. masc. adj. *caniferus* bearing (producing) white.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1 and oatmeal agar: aerial mycelium is gray; substrate mycelium is yellow, dark yellow; no diffusible pigment. On starch-ammonia agar: poor growth; aerial mycelium is gray; substrate mycelium is colorless to yellowish beige; no diffusible pigment. On glycerol-nitrate agar and glycerol-asparagine agar: aerial mycelium is white, whitish gray to gray; substrate mycelium is yellow, dark-yellow; diffusible pigment is yellow, but sometimes absent. On organic agar 2: aerial mycelium is white, later gray; substrate mycelium is colorless, yellow, or dark yellow; no diffusible pigment. Melanoid pigments are not formed. Grows on starch, inositol, mannitol, rhamnose, maltose, sucrose, and glucose; no growth on fructose, arabinose, galactose, xylose, lactose, or raffinose.

Type strain shows the highest sequence similarity to: *S. libani* subsp. *rufus*, AJ781351, 100%; *S. hygroscopius* subsp. *glebosus*, AB184479, 100%; *S. platensis*, AB045882, 99.8%; *S. libani* subsp. *libani*, AB184414, 99.6%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.6%; *S. tubercidicus*, AJ621612, 99.5%; *S. nigrescens*, DQ442530, 99.5%; *S. catenulae*, AJ621613, 99.4%; *S. misakiensis*, AB217605, 99.4%; *S. ramulosus*, DQ026662, 99.3%; *S. sioyaensis*, DQ026654, 99.2%; *S. monomycini*, DQ445790, 99%.

Type strain: VKM Ac-68, INMI 377, JCM 6914, AS 4.1588, ATCC 43699, DSM 41453, NBRC 15389, NRRL B-16358.

Sequence accession no. (16S rRNA gene): AB184640.

89. **Streptomyces canus** Heinemann, Kaplan, Muir and Hooper 1953, 1239[AL]

ca′nus. L. masc. adj. *canus* white, hoary.

Spore chains in Section *Spirales*, but some spore chains representative of Section *Rectiflexibiles* and *Retinaculiaperti* are also found. Mature spore chains are long, generally 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, except for dark brown on glycerol-asparagine agar in 14–21 d. Substrate is not a pH indicator.

Color in medium: true melanoid pigments are probably not formed in peptone-yeast-iron agar and tyrosine agar. Reports differ on production of melanoid pigments. Each of two observers reported dark pigment, but on different test media; a third collaborator saw no melanoid pigment in peptone-yeast-iron agar or tyrosine agar, but dark brown pigment in the substrate mycelium on glycerol-asparagine agar. An additional test showed no characteristic melanoid pigment. Pigments other than dark pigments noted above are not formed on yeast-malt agar, oatmeal agar, or salts-starch agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Variable reports on growth with raffinose.

Type strain shows the highest sequence similarity to: *S. ciscaucasicus*, AY508512, 99.8%; *S. pseudovenezuelae*, AB184233, 99.4%; *S. resistomycificus*, AB184166, 99.3%; *S. novaecaesareae*, AB184357, 99%.

Type strain: AS 4.1468, ATCC 12237, ATCC 19737, CBS 475.68, BCRC 13652, DSM 40017, IFM 1092, NBRC 12752, JCM 4212, JCM 4569, LMG 19329, NCIMB 9627, NRRL B-1989, NRRL B-3980, NRRL-ISP 5017, RIA 1017, UNIQEM 125, VKM Ac-1011.

Sequence accession no. (16S rRNA gene): AY999775.

90. **Streptomyces capillispiralis** Mertz and Higgens 1982, 123[VP]

ca.pil.li.spi.ra′lis. L. n. *capillus* hair; N.L. adj. *spiralis* (from L. n. *spira* a coil) spiral or spiraled; N.L. masc. adj. *capillispiralis* hairy spiraled.

Spore chains in Section *Spirales.* This morphology is readily observed on all media which support formation of aerial mycelia. Oatmeal agar (ISP 3), ISP 7, tomato paste oatmeal agar, and tap-water agar provide excellent observation of spiral morphology. The spirals are simple, open, loose coils of two to three turns. The sporophores bear chains of 10–50 spores. Spore shape is oval to globose. The spore size ranges from 0.96 to 1.19 µm by 0.54 to 0.71 µm. The mean size is 1.05 by 0.62 µm. Spore surface ornamentation is hairy. Coremia are observed on yeast-malt extract agar (ISP 2). Aerial mycelium is in the Gray color series of Tresner and Backus; light brownish-gray is the predominant shade. Produces a non-fragmenting substrate or primary mycelium which varies from yellow-brown to brownish-black, depending on the medium. A brown, water-soluble pigment is occasionally produced. Does not produce melanoid pigments.

Positive for catalase, phosphatase, and urease; decomposes casein, hypoxanthine, tyrosine, and xanthine. Liquefaction of gelatin, hydrolysis of starch, reduction of nitrate, peptonization of milk, resistance to lysozyme, and decomposition of esculin are negative. Acetate, D-arabinose, melibiose, raffinose, salicin, and sucrose are not utilized. Growth occurs at 10–45°C, with optimum growth at 30°C. Tolerates a pH range of 6–9.5, levels of NaCl up to 6%, and sucrose concentrations up to 35%. Cell analysis demonstrated the presence of LL-A_2pm; no *meso* isomer was detected. Sugar determinations indicated that only glucose and ribose were present. This information indicates a type I cell wall and a type C sugar pattern.

Type strain shows the highest sequence similarity to: *S. pseudogriseolus*, DQ442541, 100%; *S. gancidicus*, AB184660, 100%; *S. cellulosae*, DQ442495, 99.8%; *S. azureus*, EF178674, 99.5%; *S. levis*, AB184670, 99.5%; *S. lusitanus*, AB184424, 99.3%; *S. rubiginosus*, AY999810, 99.3%; *S. carpinensis*, AB184574, 99.3%; *S. matensis*, AB184221, 99.2%; *S. tuirus*, AB184690, 99.2%; *S. albaduncus*, AY999757, 99.1%; *S. caelestis*, X80824, 99.1%; *S. paradoxus*, AB184628, 99.1%; *S. djakartensis*, AB184657, 99%; *S. griseoloalbus*, AB184275, 99%; *S. afghaniensis*, AJ399483, 99%; *S. geysiriensis*, DQ442501, 99%; *S. africanus*, AY208912, 99%; *S. minutiscleroticus*, EF178696, 99%; *S. rochei*, AB184237, 99%; *S. vinaceusdrappus*, AY999929, 99%; *S. mutabilis*, EF178679, 99%; *S. ghanaensis*, AY999851, 99%; *S. plicatus*, AB184291, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: A49492, DSM 41695, NBRC 14222, JCM 5075, KCTC 1719, NCIMB 12832, NRRL 12279.

Sequence accession no. (16S rRNA gene): AB184577.

91. **Streptomyces capoamus** Gonçalves de Lima, Albert and Gonçalves de Lima 1964, 317[AL]

ca.po.a′mus. Nheêngatû Amazonian dialect *capoama* island; N.L. n. *capoamus* island, referring to Ascension Island, the source of the soil from which the organism was isolated.

Spore chains in Section *Retinaculiaperti.* Terminal spirals, loops, and hooks may be found on moderately long chains of 10–50 spores. Straight to flexuous chains are also common. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but not on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or Red color series on yeast-malt agar and salts-starch agar; Red color series on oatmeal agar. Aerial mycelium is poorly developed or absent on glycerol-asparagine agar. Nearest matching color tabs from the Gray color series are e, medium gray, and 5fe, light grayish reddish brown. Nearest matching tabs from the Red color series are 6ec, grayish yellowish pink, and 7ca, light yellowish pink. Reverse side of colony is red; light reddish brown to grayish yellowish pink on yeast-malt

agar, oatmeal agar and salts-starch agar. Reverse mycelium pigment is a pH indicator, changing from red or reddish brown to blue or violet with the addition of 0.05 M NaOH.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth, but the reaction may be weak in tyrosine agar. Yellow, red, or orange may or may not be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. One of three observers reports a pH-sensitive pigment showing essentially the same reactions noted for the reverse mycelium pigments in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Utilization of raffinose is doubtful. No growth or only traces of growth with iso-inositol, rhamnose, and sucrose.

Type strain shows the highest sequence similarity to: *S. longwoodensis*, AB184580, 99.6%; *S. canarius*, AB184396, 99.5%; *S. corchorusii*, AB184267, 99.5%; *S. olivaceoviridis*, AB184288, 99.5%; *S. galbus*, X79852, 99.5%; *S. bungoensis*, AB184696, 99.5%; *S. regensis*, DQ026649, 99.1%; *S. curacoi*, EF626595, 99%.

Source: isolated from soil from Ascension Island.

Type strain: AS 4.1696, ATCC 19006, CBS 712.72, BCRC 11860, DSM 40494, NBRC 13411, JCM 4253, JCM 4734, NRRL B-3632, NRRL-ISP 5494, RIA 1372.

Sequence accession no. (16S rRNA gene): AB045877.

92. **Streptomyces carpaticus** Maximova and Terekova 1986, 574[VP] (Effective publication: Maximova and Terekova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

car.pa′ti.cus. N.L. masc. adj. *carpaticus* of or pertaining to the Carpathians.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1, glycerol-asparagine agar, oatmeal agar, and glycerol-nitrate agar: aerial mycelium is grayish gray-brown; substrate mycelium and diffusible pigment are dark brown, nearly black with reddish or olive shadow. On starch-ammonia agar: aerial mycelium is light gray; substrate mycelium is colorless; no diffusible pigment. Sometimes substrate mycelium and diffusible pigment are light brown. On organic agar 2 and agar 79: aerial mycelium is grayish gray-brown; substrate mycelium and diffusible pigment are greenish gray-brown, reddish gray-brown; melanoid pigments are not formed.

Rhamnose is utilized for growth; weak growth is observed with sucrose, fructose, glucose, xylose, mannitol, inositol, raffinose, and arabinose. Antibiotic is not produced.

Type strain shows no sequence similarity over 99%.

Source: not known.

Type strain: AS 4.1621, ATCC 43678, DSM 41468, NBRC 15390, INA 8851, JCM 6915, NRRL B-16359, VKM Ac-1211.

Sequence accession no. (16S rRNA gene): DQ442494.

93. **Streptomyces carpinensis** (Falcão de Morais, Oliveira Da Silva and Machado 1971) Goodfellow, Williams and Alderson 1986a, 574[VP] (Effective publication: Goodfellow, Williams and Alderson 1986c, 53.) (*Elytrosporangium carpinense* Falcão de Morais, Oliveira Da Silva and Machado 1971, 205)

car.pin.en′sis. Gr. n. *karpos* fruit, seed with seed-vessel; N.L. masc. adj. *carpinensis* pertaining to spores within a sporangium.

Forms extensively branched substrate and aerial mycelium. The latter bears long spiral chains and the former bears single spores or short chain of up to seven spores of various sizes (1.0–3.0 µm diameter). The spore surface is smooth. Aerial spore mass is dark gray; the reverse color is black. Does not form melanin pigments. Adenine, esculin, casein, guanine, hypoxanthine, starch, testosterone, and tyrosine are degraded, but allantoin, arbutin, chitin, elastin, lecithin, pectin, urea, and xanthine are not. Hydrogen sulfide is produced, but nitrate is not reduced. L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, mannitol, D-mannose, melezitose, melibiose, raffinose, L-rhamnose, salicin, trehalose, and xylitol are used as sole carbon sources, but adonitol, *myo*-inositol, inulin, D-lactose, sucrose, and D-xylose are not. Grows on DL-amino-n-butyric acid, L-arginine, L-cysteine, L-histidine, L-phenylalanine, potassium nitrate, L-serine, L-threonine, and L-valine, but not on L-hydroxyproline or L-methionine, as sole nitrogen source. Growth occurs at 10, 37 and 45°C, but not at 4°C. Tolerant to phenol (0.1%, w/v), sodium azide (0.02%, w/v), and sodium chloride (7%, w/v). Resistant to rifampin but sensitive to sodium chloride at 10% (w/v). Does not show antimicrobial activity against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Saccharomyces cerevisiae* CBS 1171[T], or *Streptomyces murinus* ISP 5091. Contains major amounts of hexa- and octa-hydrogenated menaquinones with nine isoprene units.

Type strain shows the highest sequence similarity to: *S. levis*, AB184670, 99.5%; *S. cellulosae*, DQ442495, 99.4%; *S. pseudogriseolus*, DQ442541, 99.4%; *S. gancidicus*, AB184660, 99.4%; *S. capillispiralis*, AB184577, 99.3%; *S. azureus*, EF178674, 99.1%; *S. spinoverrucosus*, AB184578, 99%; *S. djakartensis*, AB184657, 99%.

Source: isolated from soil in Pernambuco, Brazil.

DNA G+C content (mol%): not known.

Type strain: 70-6-2 (Lab. Microbiol. Inst. Biociencias Univer. Federal Pernambuco, Recife, Brazil), ATCC 27116, DSM 43835, NBRC 14214, IMET 43558, JCM 3301, KCC A-0301, KCTC 9128, NRRL B 16921, RIA 982, VKM Ac-1300, VKM Ac-657.

Sequence accession no. (16S rRNA gene): AB184574.

94. **Streptomyces catenulae** Davisson and Finlay *in* Waksman 1961, 190[AL]

ca.te.nu′la.e. L. dim. n. *catenula* a small chain; L. gen. dim. n. *catenulae* of a small chain.

Spore chains in Section *Rectiflexibiles*. Very short spore chains of 3–10 spores occur in dense clusters so that morphology is difficult to determine. Short chains often form hooks or incomplete spirals. Tight spirals may occur in the dense clusters, but most chains are too short to form true spirals. Short chains are also not typical of *Retinaculiaperti*

cultures. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. It is representative of morphology described by Davisson and Finlay (op. cit). Spore surface is smooth.

Color of colony: aerial mass color in the Green color series on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar; Gray or Green color series on salts-starch agar. The color on all media is medium gray to olive gray or grayish olive (see tabs 2ih or 2ge in Gray color series and 1½ge in Green color series). Reverse side of colony is colorless or grayish yellow to light grayish olive or olive brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate mycelium pigment is not pH-sensitive.

Color in medium: melanoid pigments are not found in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth; no pigment or only trace of yellow pigment in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, D-xylose, iso-inositol, and rhamnose.

Type strain shows the highest sequence similarity to: *S. misakiensis*, AB217605, 100%; *S. libani* subsp. *libani*, AB184414, 99.6%; *S. nigrescens*, DQ442530, 99.5%; *S. tubercidicus*, AJ621612, 99.5%; *S. caniferus*, AB184640, 99.4%; *S. libani* subsp. *rufus*, AJ781351, 99.3%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.3%; *S. platensis*, AB045882, 99.2%; *S. sioyaensis*, DQ026654, 99.2%; *S. ramulosus*, DQ026662, 99.1%.

Type strain: AS 4.1701, ATCC 12476, ATCC 23893, CBS 679.68, BCRC 12092, DSM 40258, HAMBI 986, NBRC 12848, IMET 42944, JCM 4353, KCTC 9223, NRRL B-2342, NRRL-ISP 5258, RIA 1183, VKM Ac-758.

Sequence accession no. (16S rRNA gene): AJ621613.

95. **Streptomyces caviscabies** Goyer, Faucher and Beaulieu 1996, 638[VP]

ca.vi.sca'bies. L. adj. *cavus* hollow, excavated; L. n. *scabies* scab, mange; N.L. n. *caviscabies* excavated scab, referring to the ability of the organism to cause deep-pitted scab of potatoes.

The cylindrical, smooth spores are 0.87–1.08 × 0.5–0.63 µm. Strains are characterized by a gold mycelium on yeast-malt extract medium and a white mass of spores borne in flexuous chains. Does not produce melanin. All strains grow on proline or methionine as sole nitrogen source. Utilizes raffinose as a sole carbon source. All strains grow in the presence of 4% NaCl, 0.1% phenol, 10 IU/ml penicillin, 10 µg/ml thallous acetate, and 20 µg/ml streptomycin sulfate. Growth is inhibited at pH 4.5. The cell walls contain LL-A_2pm.

For sequence similarity, see type strain of *Streptomyces griseus.*

Source: not known.

DNA G+C content (mol%): 71.0.

Type strain: EF-87, ATCC 51928, CIP 104962, DSM 41811.

Sequence accession no. (16S rRNA gene): AF112160.

Further comments: according to Liu et al. (2005b), *Streptomyces caviscabies* Goyer et al. 1996 is a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 emend. Liu et al. 2005b.

According to Guo et al. (2008), *Streptomyces caviscabies* Goyer et al. (1996) is not a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948.

96a. **Streptomyces cavourensis subsp. cavourensis** Skarbek and Brady 1978, 52[AL]

ca.vour.en'sis. N.L. masc. adj. *cavourensis* of or pertaining to Cavour, named for Conti de Cavour (1810–1861), an Italian statesman and hero.

Spore chains in Section *Rectiflexibiles.* Mature spore chains are generally flexuous and very long, with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth, sometimes with minor surface irregularities.

Color of colony: aerial mass color in the Yellow color series (2db or 2ba, pale yellow) on yeast-malt agar, oatmeal agar, and salts-starch agar; Yellow or White color series on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (moderate to strong brown on yeast-malt agar; yellow, orange yellow, or olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment (other than brown) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth with iso-inositol, rhamnose, sucrose, and raffinose. Type strain shows the highest sequence similarity to: *S. celluloflavus*, AB184476, 100%; *S. albolongus*, AB184425, 100%; *S. griseobrunneus*, AB249912, 99.9%; *S. bacillaris*, AB184439, 99.4%; *S. californicus*, AB184755, 99.4%; *S. fulvorobeus*, AB184711, 99.3%; *S. floridae*, AB184656, 99.3%; *S. griseinus*, AB184205, 99.3%; *S. parvus*, DQ442537, 99.3%; *S. pluricolorescens*, DQ442540, 99.3%; *S. candidus*, DQ026663, 99.3%; *S. spiroverticillatus*, AB184814, 99.3%; *S. globisporus* subsp. *globisporus*, EF178686, 99.3%; *S. sindenensis*, AB184759, 99.3%; *S. badius*, AY999783, 99.3%; *S. praecox*, AB184293, 99.2%; *S. albovinaceus*, AB249958, 99.2%; *S. microflavus*, DQ445795, 99.2%; *S. fimicarius*, AY999784, 99.2%; *S. flavofuscus*, AB249935, 99.2%; *S. alboviridis*, AB184256, 99.2%; *S. rubiginosohelvolus*, AB184240, 99.2%; *S. lipmanii*, AB184148, 99.2%; *S. mediolani*, AB184674, 99.2%; *S. cremeus*, AB184124, 99.2%; *S. nitrosporeus*, EF178680, 99.1%; *S. anulatus*, DQ026637, 99.1%; *S. acrimycini*, AY999889, 99.1%; *S. griseoplanus*, AY999894, 99.1%; *S. baarnensis*, EF178688, 99.1%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.1%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.1%; *S. argenteolus*, AB045872, 99%; *S. flavovirens*, DQ026635, 99%; *S. cinereorectus*, AB184646, 99%; *S. cyaneofuscatus*, AB184860, 99%; *S. finlayi*, AY999788, 99%; *S. luridiscabiei*, AF361784, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1692, ATCC 14889, ATCC 25438, CBS 669.69, DSM 40300, NBRC 13026, JCM 4249, JCM 4298, JCM 4555, NCIMB 8918, NRRL 2740, NRRL-ISP 5300, RIA 1218, VKM Ac-731.

Sequence accession no. (16S rRNA gene): DQ445791.

96b. **Streptomyces cavourensis subsp. washingtonensis** Skarbek and Brady 1978, 52[AL]

wash.ing.ton.en′sis. N.L. masc. adj. *washingtonensis* of or pertaining to Washington.

Strain exhibits straight to flexuous chains of spores on all standard media and thus belongs to the section *Rectiflexibiles*. The spore type is smooth. Malate is moderately solubilized by all strains tested, except one, which gave a weak response. No distinctive pigments other than yellow-brown are found in the reverse mycelium (i.e. reverse side of colony) of cultures. Diffusible, soluble pigments other than brown or black are found only with one strain grown on the standard media. This yellow, soluble pigment is not a pH indicator. All cultures, except that of strain Illinois 205-2M, are found to produce melanoid pigments on at least three of the four media which were utilized. Strain Illinois 205-2M failed to produce melanoid pigments on any of the melanin formation media employed.

Tolerance to heavy metals is as follows. Strain AUW-83 differs from all the other strains in that it produces a soluble, dark brown pigment, modified by gray-green, after 10 d of incubation on the basal agar supplemented with zinc; little soluble pigment, except for a slight yellow-brown exhibited by strain 689, was observed with the remaining strains on the zinc agar.

Type strain shows the highest sequence similarity to: *S. cyaneofuscatus*, AB184860, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. alboviridis*, AB184256, 100%; *S. fulvorobeus*, AB184711, 100%; *S. praecox*, AB184293, 100%; *S. anulatus*, DQ026637, 100%; *S. flavofuscus*, AB249935, 100%; *S. cinereorectus*, AB184646, 100%; *S. griseoplanus*, AY999894, 100%; *S. lipmanii*, AB184148, 100%; *S. fimicarius*, AY999784, 100%; *S. microflavus*, DQ445795, 99.9%; *S. sindenensis*, AB184759, 99.9%; *S. rubiginosohelvolus*, AB184240, 99.9%; *S. mediolani*, AB184674, 99.9%; *S. griseinus*, AB184205, 99.9%; *S. acrimycini*, AY999889, 99.9%; *S. pluricolorescens*, DQ442540, 99.9%; *S. argenteolus*, AB045872, 99.9%; *S. badius*, AY999783, 99.9%; *S. floridae*, AB184656, 99.8%; *S. albovinaceus*, AB249958, 99.8%; *S. globisporus* subsp. *globisporus*, EF178686, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.8%; *S. griseolus*, AB184768, 99.8%; *S. luridiscabiei*, AF361784, 99.8%; *S. baarnensis*, EF178688, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. californicus*, AB184755, 99.7%; *S. parvus*, DQ442537, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. flavogriseus*, AJ494864, 99.6%; *S. olivoviridis*, AB184227, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. atroolivaceus*, AJ781320, 99.5%; *S. clavifer*, DQ026670, 99.4%; *S. yanii*, AB006159, 99.4%; *S. nitrosporeus*, EF178680, 99.4%; *S. albolongus*, AB184425, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. mutomycini*, AB249951, 99.2%; *S. atratus*, DQ026638, 99.2%; *S. celluloflavus*, AB184476, 99.2%; *S. gelaticus*, DQ026636, 99.2%; *S. griseobrunneus*, AB249912, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.1%; *S. cremeus*, AB184124, 99.1%; *S. candidus*, DQ026663, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1635, ATCC 27732, DSM 41423, NBRC 15391, JCM 4967, NRRL B-8030.

Sequence accession no. (16S rRNA gene): DQ026671.

97. **Streptomyces cellostaticus** Hamada 1958, 178[AL]

Etymology of specific epithet is unknown.

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50 spores per chain; longer chains are often observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red (or Gray) color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Characteristic color is usually between 3ge (light grayish yellowish brown) and 5ge or 5dc (grayish yellowish pink) color tabs of Tresner–Backus color wheels. Reverse side of colony with no distinctive pigment (characteristic grayed yellow or light yellow brown) on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids or faint traces of yellow pigment not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. griseochromogenes*, AB184387, 99.7%; *S. yokosukanensis*, DQ026652, 99.5%; *S. achromogenes* subsp. *achromogenes*, AB184109, 99%; *S. griseoruber*, AB184209, 99%; *S. olivaceoviridis*, AB184288, 99%; *S. corchorusii*, AB184267, 99%.

Sequence accession no. (16S rRNA gene): AB184192.

98. **Streptomyces celluloflavus** Nishimura, Kimura and Kuroya 1953, 64[AL]

cel.lu.lo.fla′vus. N.L. n. *cellulosum* cellulose; L. adj. *flavus* yellow; N.L. masc. adj. *celluloflavus* cellulose, yellow (intended to refer to the yellow streptomycete that attacks cellulose).

Sparse formation of aerial mycelium. Poor growth on Czapek's solution agar. Produces aureothricin; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *cavourensis*, DQ445791, 100%; *S. albolongus*, AB184425, 100%; *S. griseobrunneus*, AB249912, 100%; *S. californicus*, AB184755, 99.5%; *S. bacillaris*, AB184439, 99.4%; *S. fulvorobeus*, AB184711, 99.4%; *S. floridae*,

Type strain: AS 4.1659, ATCC 29806, CECT 3242, DSM 40839, NBRC 13780, JCM 4126, KCTC 9702, NRRL B-2493.

Sequence accession no. (16S rRNA gene): AB184476.

99. **Streptomyces cellulolyticus** Li 1997, 444[VP]

cel.lu.lo.ly′ti.cus. N.L. n. *cellulosum* cellulose; N.L. masc. adj. *lyticus* (from Gr. masc. adj. *lutikos*) able to dissolve; N.L. masc. adj. *cellulolyticus* decomposing cellulose.

Spore chains are *Rectiflexibiles*, with 20 or more spores per chain. Spores are oval and are 2.1–2.3 × 2.5–2.7 µm. Spore surface is warty. Mycelia do not fragment into coccoid or bacillary structures. The branching substrate mycelium is: yellow on yeast extract-malt extract agar, inorganic salts-starch agar, glucose-asparagine agar, and nutrient agar; brown on glycerol-asparagine agar, tyrosine agar, and Czapek's solution agar; and colorless on oatmeal agar. Aerial spore mass is white to pink. Soluble pigments, including melanin, are not produced. Cellulose is decomposed. D-Glucose, D-fructose, L-arabinose, sucrose, D-xylose, raffinose, and iso-inositol are utilized for growth, but rhamnose is not utilized. L-Asparagine, L-cysteine, and L-threonine can be used as nitrogen sources. Positive for catalase activity and production of H_2S and negative for oxidase activity and indole production. Nitrate is reduced. Starch, casein, and esculin are hydrolyzed. Gelatin is not liquefied. Good growth occurs at pH 7.2 and the optimum temperature is 30°C. Growth occurs in the presence of up to 10% NaCl. Isolate LX[T] is susceptible to penicillin G, but not to dimethylchlortetracycline, vancomycin, kanamycin, rifampin, or aminobenzylpenicillin. The cell-wall chemotype is chemotype I and the cell wall contains LL-A_2pm and glycine; no characteristic sugars are detected as whole-cell sugars.

101. **Streptomyces champavatii** Uma and Narasimha Rao 1959, 133[AL]

cham.pa.va′ti.i. N.L. gen. n. *champavatii* of Champavathi, named after the Champavathi River in Andhra Pradesh, India.

Forms green vegetative mycelium and diffusible pigment on some media. Poor growth on Czapek's solution agar; produces champamycins A and B (heptaenic antifungal antibiotics) and champavatin, a non-polyenic antifungal antibiotic; produces vitamin B_{12}.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. hydrogenans*, AB184868, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 99.9%; *S. canescens*, AB184117, 99.9%; *S. koyangensis*, AY079156, 99.5%; *S. sampsonii*, D63871, 99.3%.

Type strain: AS 4.1615, BCRC 12231, DSM 40841, NBRC 15392, JCM 5066, NCIMB 12859, NRRL B-5682.

Sequence accession no. (16S rRNA gene): DQ026642.

102. **Streptomyces chartreusis** Leach, Calhoun, Johnson, Teeters and Jackson 1953, 4011[AL] ["*Actinomyces chartreusis*" Preobrazhenskaya 1966, 852]

char.treu′sis. N.L. n. *chartreusum* (from French n. *chartreuse*), a Carthusian monastery famed for a sweet yellow liqueur, hence the color "chartreuse"; N.L. masc. adj. *chartreusis* yellow, referring to color of the diffusible pigment formed by the organism.

Spore chains in Section *Spirales*. Clusters of spiral spore chains sometimes resemble whorls of verticils. Pseudoverticils are not uniformly distributed and do not arise from an acial hypha characteristic of true verticillate forms. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Blue color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (Gray series also reported on oatmeal agar). Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. resistomycificus*, AB184166, 99.5%; *S. galilaeus*, AB045878, 99.3%; *S. bobili*, AB249925, 99.3%; *S. novaecaesareae*, AB184357, 99.1%; *S. phaeoluteigriseus*, AJ391815, 99.1%; *S. pseudovenezuelae*, AB184233, 99.1%; *S. prunicolor*, DQ026659, 99%; *S. aureocirculatus*, AB184260, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1639, ATCC 14922, ATCC 19738, CBS 476.68, BCRC 13673, CCT 5005, DSM 40085, NBRC 12753, JCM 4570, KCTC 9704, NRRL 2287, NRRL-ISP 5085, RIA 1018, UNIQEM 126, VKM Ac-1721.

Sequence accession no. (16S rRNA gene): AB184839.

103. **Streptomyces chattanoogensis** Burns and Holtman 1959, 398[AL]

chat.ta.no.o.gen′sis. N.L. masc. adj. *chattanoogensis* of or belonging to Chattanooga, Tennessee, the source of the soil from which the organism was isolated.

Spore chains Section *Spirales*, but spore chains representative of Section *Rectiflexibiles* and Section *Retinaculiaperti* are also found. Mature spore chains generally have 10–50 spores per chain on suitable media. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Yellow or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Yellow, when present, is a very pale yellow. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. Yellow pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, iso-inositol, D-mannitol, D-fructose, raffinose, and sucrose are utilized for growth. No growth or only traces of growth on D-xylose, rhamnose, and L-arabinose.

Type strain shows the highest sequence similarity to: *S. lydicus*, Y15507, 99.8%; *S. sioyaensis*, DQ026654, 99.3%; *S. rimosus* subsp. *paromomycinus*, AJ621610, 99.2%; *S. chrestomyceticus*, AJ621609, 99.2%; *S. tubercidicus*, AJ621612, 99%; *S. libani* subsp. *libani*, AB184414, 99%; *S. nigrescens*, DQ442530, 99%.

Source: isolated from soil from Chattanooga, Tennessee, USA.

DNA G+C content (mol%): not known.

Type strain: AS 4.1415, ATCC 13358, ATCC 19739, CBS 477.68, BCRC 13655, CECT 3321, DSM 40002, NBRC 12754, JCM 4299, JCM 4571, KCTC 1087, LMG 19339, NCIMB 9809, NRRL B-2255, NRRL-ISP 5002, RIA 1019, VKM Ac-1775.

Sequence accession no. (16S rRNA gene): AJ621611.

104. **Streptomyces cheonanensis** Kim, Lee and Hwang 2006, 474[AL]

che.on.an.en′sis. N.L. masc. adj. *cheonanensis* of or pertaining to Cheonan, Republic of Korea, the geographical origin of the type strain.

Forms extensively branched aerial and substrate hyphae. Short or long, straight to flexuous chains of smooth-surfaced spores are evident on the aerial hyphae. Aerial mycelium is gray to white and the substrate mycelium appears light yellow when grown on ISP 4 agar. Aerial and substrate mycelia grow abundantly on both ISP 3 agar and Bennett's agar. Soluble pigments are generated on ISP3, ISP 3, ISP 5 (glycerol-asparagine agar), and ISP 7. The cell wall contains LL-A_2pm. Predominant cellular fatty acids are 14-methylpentadecanoic acid ($C_{16:0}$ iso; 47.82%), hexadecanoic acid ($C_{16:0}$; 14.44%), and *cis*-9-hexadecenoic acid ($C_{16:1}$ *cis9*; 10.24%). Optimum growth occurs at 29°C. Grows well in yeast extract-malt extract broth adjusted to pH 6.5–8.0. Tolerates NaCl concentrations up to 7%. Capable of utilizing several carbon sources, including adonitol, arabinose, dextran, fructose, *myo*-inositol, mannitol, melezitose, melibiose, raffinose, L-rhamnose, sucrose, xylitol, and xylose. Can also use several nitrogen sources: DL-α-amino-n-butyric acid, L-cysteine, L-histidine, L-hydroxyproline, L-phenylalanine, and L-valine. Resistant to penicillin G, but sensitive to neomycin, oleandomycin, and rifampin. Secretes compounds the inhibit mycelial growth of plant-pathogenic fungi including *Alternaria mali*, *Collectotrichum orbiculare*, *Magnaporthe grisea*, *Fusarium oxysporum* f. sp. *lycopersici*, and *Rhizotonia solani* and the oomycete *Phytophthora capsici*.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. thermolineatus* DSM 41451ᵀ, 21.5%; "*S. cattleya*" JCM 4925, 39.8%; *S. macrosporus* DSM 41449ᵀ, 19.8%; *S. acidiscabies* ATCC 49003ᵀ, 60.6%.

Source: not known.

DNA G+C content (mol%): 75.5.

Type strain: VC-A46, KCCM 42119, NBRC 100940.

Sequence accession no. (16S rRNA gene): AY822606.

105. **Streptomyces chibaensis** Suzuki, Nakamura, Okama and Tomiyama 1958, 81[AL]

chi.ba.en′sis. N.L. masc. adj. *chibaensis* of or belonging to Chiba City, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales* or *Rectiflexibiles*. Spirals, when formed, are open and poorly developed. Some spore chains are straight and many are flexuous or curved to form hooks or partial spirals. Most spore chains are too short (3 to 10 or 20 spores per chain) for this culture to be placed in Section *Retinaculiaperti*. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: mature aerial mass color is usually in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar; Gray or Yellow color series on glycerol-asparagine agar. Color tabs selected from the Gray color series were yellowish gray or grayish yellowish brown. Reverse side of colony with no distinctive pigments (grayed greenish yellow, yellow, or rarely orange-yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not found in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment may or may not be found in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar; this pigment is not pH-sensitive.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are all utilized for growth.

For sequence similarity, see type strain of *Streptomyces corchorusii*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1654, ATCC 23895, CBS 681.68, DSM 40220, IFM 1085, NBRC 12850, JCM 4017, JCM 4632, KCTC 9786, LMG 20456, NRRL B-2904, NRRL-ISP 5220, RIA 1164, VKM Ac-1893.

Sequence accession no. (16S rRNA gene): AB184193.

Further comments: according to Lanoot et al. (2005b), *Streptomyces chibaensis* Suzuki et al. 1958 is a later heterotypic synonym of *Streptomyces corchorusii* Ahmad and Bhuiyan 1958 emend. Lanoot et al. 2005b.

According to Rule 24b of the *Bacteriological Code* (1990 Revision), if two names compete for priority and if both names are listed on the Approved Lists of Bacterial Names, the priority shall be determined by the date of the effective publication of the name before 1 January 1980. *Streptomyces chibaensis* and *Streptomyces corchorusii* are cited in the Approved Lists. The dates of effective publications are 1958. Consequently, to determine priority it is necessary to know the month (and perhaps the day) of the effective publications. *Streptomyces chibaensis* was effectively published in the *Journal of Antibiotics* (*Tokyo*) *Series A*, 1958, vol. 11, pp. 81–83, and *Streptomyces corchorusii* in the *Pakistan Journal of Biological and Agricultural Sciences*, 1958, vol. 1, pp. 137–143. It is certainly not easy to know the exact dates of publication of these articles. However, according to Rule 42 of the *Bacteriological Code* (1990 Revision), if the epithets are of the same date, the author who first unites the taxa has the right to choose one of them, and his choice must be followed. Lanoot et al. chose the epithet *corchorusii*.

106. **Streptomyces chrestomyceticus** Canevazzi and Scotti 1959, 248[AL]

chres.to.my.ce′ti.cus. N.L. n. *chrestomycinum* chrestomycin, name of an antibiotic; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *chrestomyceticus* belonging to chrestomycin.

Spore chains in Section *Spirales*. Spirals are often irregular and may become entangled. Mature spore chains generally are long with 10 to 50 or often more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Special morphological characteristics are moist droplets (hygroscopic droplets are sometimes found on oatmeal agar; one observer describes these as similar to sporangia of *Actinosporangium*). Coremia may also be formed on salts-starch agar or glycerol-asparagine agar.

Color of colony: aerial mass color in the Yellow or White color series on yeast-malt agar and glycerol-asparagine agar; White color series on salts-starch agar; Green or White color series on oatmeal agar. Nearest matching color tabs in the Yellow color series are ½ec to 1dc, pale yellow green; 2ba, pale yellow; and 2fb, light yellow. Nearest matching color tab in the Green color series is 1½ge, light grayish olive. Reverse side of colony with no distinctive pigments (colorless to pale yellow or light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, tryptone-yeast broth, or Gause's medium no. 2. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-mannitol, and D-fructose are utilized for growth. Utilization of sucrose, D-xylose, iso-inositol, and raffinose is doubtful. No growth or only traces of growth with rhamnose.

Type strain shows the highest sequence similarity to: *S. rimosus* subsp. *paromomycinus*, AJ621610, 100%; *S. albofaciens*, AB045880, 99.7%; *S. lydicus*, Y15507, 99.3%; *S. erumpens*, AJ621603, 99.3%; *S. chattanoogensis*, AJ621611, 99.2%; *S. sclerotialus*, AJ621608, 99.1%; *S. sioyaensis*, DQ026654, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1657, ATCC 14947, CBS 745.72, BCRC 12173, DSM 40545, NBRC 13444, JCM 4735, NCAIM B.01478, NCIMB 8995, NRRL B-3293, NRRL B-3310, NRRL B-3672, NRRL-ISP 5545, RIA 1405.

Sequence accession no. (16S rRNA gene): AJ621609.

Further comments: the ISP description of this strain differs from the original description with respect to spiral spore chains versus very short *Rectiflexibiles* chains, Yellow or Green aerial mycelium versus White, and in growth on L-arabinose.

107. **Streptomyces chromofuscus** (Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 68[AL] ("*Actinomyces chromofuscus*" Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 176)

chro.mo.fus′cus. Gr. n. *chroma* color; L. adj. *fuscus* dark, tawny; N.L. masc. adj. *chromofuscus* dark or tawny colored.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow to olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. Pigments other than melanoids or faint traces of yellow are not found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on utilization of raffinose and iso-inositol. No growth or only traces of growth on sucrose.

Type strain shows the highest sequence similarity to: *S. cinereospinus*, AB184648, 99.1%; *S. coeruleofuscus*, DQ026668, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1451, ATCC 23896, CBS 682.68, DSM 40273, NBRC 12851, INA 13638/58, JCM 4354, LMG 19317, NRRL B-12175, NRRL-ISP 5273, RIA 1191, VKM Ac-974.

Sequence accession no. (16S rRNA gene): AB184194.

108. **Streptomyces chryseus** (Krasil'nikov, Korenyako and Nikitina *in* Krasil'nikov 1965) Pridham 1970, 10[AL] ("*Actinomyces chryseus*" Krasil'nikov, Korenyako and Nikitina *in* Krasil'nikov 1965, 224)

chry′se.us. N.L. masc. adj. *chryseus* (from Gr. masc. adj. *khruseos*) golden.

Spore chains in Section *Spirales* on oatmeal agar or salts-starch agar, but flexuous spore chains suggesting *Rectiflexibiles* morphology may be common on these media and are the predominant morphology on glycerol-asparagine agar. Sporulating aerial mycelium is poorly developed or absent on yeast-malt agar. Mature spore chains are moderately long with 10 to 50 or more spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5ca, light yellowish pink, or 3ca, pale orange-yellow) on oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 14–21 d. White aerial mycelium may also be seen on these media. Reverse side of colony is pale yellow to light yellowish brown or orange-yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, and D-fructose are utilized for growth. Reports vary on utilization of D-xylose and iso-inositol. No growth or only traces of growth with D-mannitol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. flavidovirens*, AB184270, 100%; *S. helvaticus*, AB184367, 100%; *S. albidochromogenes*, AB249953, 99.9%; *S. enissocaesilis*, AB249930, 99.1%.

109a. **Streptomyces chrysomallus subsp. chrysomallus** Lindenbein 1952, 369[AL]

chry.so′mal.lus. N.L. masc. adj. *chrysomallus* (from Gr. masc. adj. *khrusomallos*) with golden wool.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. Typical morphology on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth (some surface irregularities are present, but are less distinct than on characteristic warty spores).

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (yellow to grayed-yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar or tyrosine agar. Yellow pigment found in medium in yeast-malt agar and oatmeal agar; traces of yellow pigment may be formed in salts-starch agar and glycerol-asparagine agar. This pigment is not a pH indicator.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, and raffinose.

For sequence similarity, see type strain of *Streptomyces anulatus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1676, ATCC 11523, BCRC 11511, DSM 40128, NBRC 15393, IMET 41360, JCM 4296, LMG 20459, NRRL 2250, NRRL 2280, UNIQEM 127.

Sequence accession no. (16S rRNA gene): AB184644.

Further comments: Lanoot et al. (2005b) are of the opinion that *Streptomyces chrysomallus* subsp. *chrysomallus* Lindenbein 1952 is a later heterotypic synonym of *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953. The type of the subspecies *Streptomyces chrysomallus* subsp. *chrysomallus* is automatically the type of *Streptomyces chrysomallus* Lindenbein 1952[AL]. Consequently, if an author agrees with Lanoot et al., *Streptomyces chrysomallus* must be considered as a later heterotypic synonym of *Streptomyces anulatus*. In expressing that opinion, Lanoot et al. (2005b) have placed the type of *Streptomyces chrysomallus* in a different species. In this case, Rule 37a of the *Bacteriological Code* (1990 Revision) applies and the authors should have dealt with the nomenclature and taxonomic position of *Streptomyces chrysomallus* subsp. *fumigatus* Frommer 1959. Authors who follow the proposal to treat the types of *Streptomyces anulatus* and *Streptomyces chrysomallus* (including the subspecies *Streptomyces chrysomallus* subsp. *chrysomallus*) as synonyms are not at liberty to use the name *Streptomyces chrysomallus* subsp. *fumigatus* and must make a taxonomic proposal for placing this subspecies in another species or subspecies.

109b. **Streptomyces chrysomallus subsp. fumigatus** Frommer 1959, 202[AL]

fu.mi.ga′tus. L. masc. part. adj. *fumigatus* smoked.

Produces the actinomycin C complex; inhibited by streptomycin; poor growth on Czapek's solution agar.

Type strain shows the highest sequence similarity to: *S. purpureus*, AJ781324, 99.9%; *S. herbaricolor*, AB184801, 99.5%; *S. indigoferus*, AB184214, 99.5%; *S. aburaviensis*, AY999779, 99.5%; *S. xanthocidicus*, AY999858, 99.4%; *S. psammoticus*, AY999862, 99.3%; *S. avellaneus*, AB184413, 99.2%. Type strain shows the highest sequence similarity to following *Kitasatospora*: *Kitasatospora kifunensis*, AB022874, 99.2%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1589, DSM 41424, NBRC 15394, JCM 3371, KCTC 9705, NRRL B-2289.

Sequence accession no. (16S rRNA gene): AB184645.

Further comments: Lanoot et al. (2005b) are of the opinion that *Streptomyces chrysomallus* subsp. *chrysomallus* Lindenbein 1952 is a later heterotypic synonym of *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953. The type of the subspecies *Streptomyces chrysomallus* subsp. *chrysomallus* is automatically the type of *Streptomyces chrysomallus* Lindenbein 1952[AL]. So, in expressing that opinion Lanoot et al. have placed the type of *Streptomyces chrysomallus* in a different species. In this case, Rule 37a of the *Bacteriological Code* (1990 Revision) applies and the authors should have dealt with the nomenclature and taxonomic position of *Streptomyces chrysomallus* subsp. *fumigatus* Frommer 1959. Authors who follow the proposal to treat the types of *Streptomyces anulatus* and *Streptomyces chrysomallus* (including the subspecies *Streptomyces chrysomallus* subsp. *chrysomallus*) as synonyms are not at liberty to use the name *Streptomyces chrysomallus* subsp. *fumigatus* and must make a taxonomic proposal for placing this subspecies in another species or subspecies.

110. **Streptomyces cinereorectus** Terekhova and Preobrazhenskaya 1986, 574[VP] (Effective publication: Terekhova and Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) emend. Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2004, 88.)

ci.ne.re.o.rec′tus. L. adj. *cinereus* similar to ashes, ash-colored; L. adj. *rectus* straight; N.L. masc. adj. *cinereorectus* ash-colored, straight.

Spore chains are straight, short, up to 10 spores per chain (*Rectiflexibiles*); spores are smooth. On mineral agar 1, oatmeal agar, and starch-ammonia agar: moderate or poor growth; aerial mycelium is poor, light gray; substrate mycelium colorless; no diffusible pigment. Glycerol-nitrate agar: abundant growth; aerial mycelium is gray; substrate mycelium grayish yellowish; no diffusible pigment. On glycerol-asparagine agar: moderate growth; aerial mycelium is gray; substrate mycelium colorless; no diffusible pigment. On organic agar 2: no aerial mycelium; substrate mycelium is colorless to yellowish; no diffusible pigment. Melanoid pigments are not formed. Good growth on glucose; moderate growth on fructose and mannitol; poor growth on raffinose; no growth on rhamnose or xylose. Forms antibiotic penicillin N. Contains LL-A_2pm and no diagnostic sugars in whole-cell hydrolysates.

Type strain shows the highest sequence similarity to: *S. argenteolus*, AB045872, 100%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. fulvorobeus*, AB184711, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. alboviridis*, AB184256, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. praecox*, AB184293, 99.9%; *S. griseolus*, AB184768, 99.9%; *S. anulatus*, DQ026637, 99.9%; *S. microflavus*, DQ445795, 99.9%; *S. halstedii*, EF178695, 99.8%; *S. pluricolorescens*, DQ442540, 99.8%; *S. sindenensis*, AB184759, 99.8%; *S. griseinus*, AB184205, 99.8%; *S. badius*, AY999783, 99.8%; *S. mediolani*, AB184674, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. rubiginosohelvolus*, AB184240, 99.8%; *S. albovinaceus*, AB249958, 99.7%; *S. flavogriseus*, AJ494864, 99.7%; *S. parvus*, DQ442537, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. floridae*, AB184656, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. californicus*, AB184755, 99.7%; *S. globisporus* subsp. *globisporus*, EF178686, 99.7%; *S. yanii*, AB006159, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. finlayi*, AY999788, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. atroolivaceus*, AJ781320, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. sanglieri*, AB249945, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. albolongus*, AB184425, 99.2%; *S. gelaticus*, DQ026636, 99.2%; *S. celluloflavus*, AB184476, 99.2%; *S. mutomycini*,

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1622, ATCC 43679, DSM 41469, NBRC 15395, INA 5202, JCM 6916.

Sequence accession no. (16S rRNA gene): AB184646.

Further comments: according to Lanoot et al. (2004), *Streptomyces cinereorectus* Terekhova and Preobrazhenskaya 1986 is an earlier heterotypic synonym of *Streptomyces cochleatus* Nakagaito et al. 1993b.

111a. **Streptomyces cinereoruber subsp. cinereoruber** Corbaz, Ettlinger, Keller-Schierlein and Zähner 1957b, 331[AL]

ci.ne.re.o.ru′ber. L. adj. *cinereus* similar to ashes, ash-colored; L. adj. *ruber* red; N.L. masc. adj. *cinereoruber* ashy red.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are long, often more than 50 spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on oatmeal agar; Red series or Gray series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Nearly all color tabs selected by collaborators are near-gray containing some pink or red. Reverse side of colony is the characteristic grayed yellow modified by red on yeast-malt agar or red to violet on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. A change from red to blue reverse color by addition of 0.05 M NaOH is reported by one observer only.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth. Pigments other than melanoids are probably not formed in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose. Growth on D-fructose is doubtful.

Type strain shows the highest sequence similarity to: *S. violaceorectus*, AB184314, 99.7%; *S. showdoensis*, AB184389, 99.5%; *S. viridobrunneus*, AJ781372, 99.4%; *S. bikiniensis*, X79851, 99.3%; *S. tanashiensis*, AJ781362, 99.1%; *S. nashvillensis*, AB184286, 99.1%; *S. vietnamensis*, DQ311081, 99%; *S. litmocidini*, AB184149, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1698, ATCC 19740, CBS 479.68, BCRC 11816, DSM 40012, NBRC 12756, JCM 4205, JCM 4572, KCTC 9706, NCIMB 9797, NRRL 2589, NRRL-ISP 5012, RIA 1021, RIA 535, UNIQEM 116, VKM Ac-1860.

Sequence accession no. (16S rRNA gene): AB184121.

111b. **Streptomyces cinereoruber subsp. fructofermentans** Corbaz, Ettlinger, Keller-Schierlein and Zähner 1957b, 331[AL]

fruc.to.fer.men′tans. L. n. *fructus* fruit; L. part. adj. *fermentans* fermenting; N.L. part. adj. *fructofermentans* fruit fermenting (but pertaining to ability of the organism to utilize L-rhamnose, D-fructose, and D-sorbitol).

Moderate growth on Czapek's solution agar; vegetative growth and diffusible pigment in tints and shades of red on some media. Produces cinerobin A and cinerobin B; inhibited by streptomycin.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1593, DSM 40692, NBRC 15396, JCM 4956, KCTC 9707, NRRL 2588.

Sequence accession no. (16S rRNA gene): AY999758.

112. **Streptomyces cinereospinus** Terekhova, Preobrazhenskaya and Gause 1986, 574[VP] (Effective publication: Terekhova, Preobrazhenskaya and Gause *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

ci.ne.re.o.spi′nus. L. adj. *cinereus* similar to ashes, ash-colored; L. adj. *spineus* spiny; N.L. masc. adj. *cinereospinus (sic)* ash-colored, spiny.

Spore chains are spirals (*Spirales*); spores are spiny, spines are short. On mineral agar 1: aerial mycelium is gray or greenish gray; substrate mycelium is colorless or, after several days, light yellow; no diffusible pigment. On glycerol-nitrate agar: no aerial mycelium; substrate mycelium and diffusible pigment are blue-green to dark gray-green. On oatmeal agar: aerial mycelium is greenish gray; substrate mycelium is colorless or, after several days, spotted green; no diffusible pigment. On starch-ammonia agar: aerial mycelium is gray, greenish gray; substrate mycelium is colorless; no diffusible pigment. On glycerol-asparagine agar: no aerial mycelium; substrate mycelium and diffusible pigment are colorless or light pink to blue-green. On glucose-asparagine agar: no aerial mycelium, substrate mycelium is colorless; diffusible pigment is light pink. On organic agar 2: no aerial mycelium; substrate mycelium colorless; no diffusible pigment. Melanoid pigments are not formed. Moderate growth on glycerin and glucose; poor growth on mannitol, rhamnose, and fructose; no growth on raffinose, inositol, arabinose, xylose, or sugar. Forms antibiotic 1719 from group azotomycin.

Type strain shows the highest sequence similarity to: *S. coeruleofuscus*, DQ026668, 99.2%; *S. chromofuscus*, AB184194, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.163, ATCC 43680, DSM 41470, NBRC 15397, INA 1719, JCM 6917, VKM Ac-1215.

Sequence accession no. (16S rRNA gene): AB184648.

113. **Streptomyces cinereus** (Cross, Lechevalier and Lechevalier 1963) Goodfellow, Williams and Alderson 1986a, 574[VP] (Effective publication: Goodfellow, Williams and Alderson 1986a, 53.) (*Microellobosporia cinerea* Cross, Lechevalier and Lechevalier 1963, 428)

ci.ne′re.us. L. masc. adj. *cinereus* ash-colored.

Short straight spore chains (2–5); spore surface is smooth; spores are round to oval and borne in both the

substrate and aerial mycelium. Spores sizes vary from 1.5 to 3.5 μm (mean diameter 2.5 μm). Extensively branched substrate and aerial mycelium. The aerial spore mass is white; reverse color is red-orange and the pigment is sensitive to pH. Does not form melanin pigments. Adenine, esculin, allantoin, arbutin, casein, hypoxanthine, starch, testosterone, tyrosine, and urea are degraded, but chitin, elastin, guanine, lecithin, pectin, xanthine, and xylan are not. Hydrogen sulfide is produced but nitrate is not reduced. L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, inulin, D-lactose, mannitol, D-mannose, melibiose, melezitose, raffinose, L-rhamnose, salicin, sucrose, trehalose, and D-xylose are used as sole carbon sources, but adonitol and xylitol are not. Grows on L-arginine, L-histidine, potassium nitrate, L-threonine, and L-valine, but not on DL-α-amino-n-butyric acid, L-cysteine, L-hydroxyproline, L-methionine, and L-phenylalanine, as sole nitrogen source. Growth occurs at 10–37°C but not at 4 or 45°C. Tolerant to phenol (0.1%, w/v) and sodium chloride (7%, w/v) but not to sodium azide (0.01%, w/v). Resistant to rifampin but sensitive to sodium chloride (10%, w/v). Antimicrobial activity is shown against *Bacillus subtilis* NCIB 3610, but not against *Aspergillus niger* LIV 131, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046[T], *Saccharomyces cerevisiae* CBS 1171[T], or *Streptomyces murinus* ISP 5091. The peptidoglycan contains LL-A_2pm as the major diamino acid and is of the A3γ type (Stackebrandt et al., 1981). Contains major amounts of hexa- and octahydrogenated menaquinones with nine isoprene units (Collins et al., 1984).

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): 67.6.

Type strain: AS 4.1672, ATCC 15840, CBS 356.67, BCRC 11616, DSM 43033, IFM 1137, IFM 1237, NBRC 12247, IMET 43557, JCM 3040, KCC A-0040, KCTC 9066, NCIMB 9586, NRRL B-2909, VKM Ac-812.

Sequence accession no. (16S rRNA gene): AB184072.

114. **Streptomyces cinerochromogenes** Miyairi, Tajashima, Shimizu and Sakai 1966, 58[AL]

ci.ne.ro.chro.mo′ge.nes. L. adj. *cinereus* similar to ashes, ash-colored; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *cinerochromogenes* producing ashy color.

Produces the anti-bacterial antibiotics cineromycin A and cineromycin B. Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: Fuji 50, AS 4.162, ATCC 33339, DSM 41651, NBRC 13822, JCM 3385, NRRL B-16928.

Sequence accession no. (16S rRNA gene): AB184507.

115. **Streptomyces cinnabarinus** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 62[AL] ("*Actinomyces cinnabarinus*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 196)

cin.na.ba′ri.nus. N.L. masc. adj. *cinnabarinus* of cinnabar, referring to the vermilion color of vegetative mycelium and diffusible pigment.

Spore chains in Section *Rectiflexibiles* but a very small proportion of strongly flexuous spore chains may suggest *Retinaculiaperti* or *Spiral* morphology on yeast-malt agar or oatmeal agar. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar. Sporulating aerial mycelium is poorly developed or absent on glycerol-asparagine agar and yeast-malt agar. Spore surface is smooth; spores of phalangeal type are common.

Color of colony: aerial mass color in the Red color series (3ca, pale orange yellow) on oatmeal agar and salts-starch agar and also on yeast-malt agar when adequate sporulation occurs on this medium. White aerial mycelium may also be seen on these media. Mature sporulating mycelium is inadequate for aerial mass color determination on glycerol-asparagine agar. Reverse side of colony is pale yellow or grayish on yeast-malt agar; yellow is modified by red to yellowish pink or reddish gray on oatmeal agar and to reddish orange, grayish red or reddish brown on salts-starch agar and glycerol-asparagine agar. Substrate pigment is not a pH indicator or is changed only slightly by addition of 0.05 M NaOH or HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth. Red or lavender pigment is found in the medium in oatmeal agar and salts-starch agar. One observer only found this pigment to be pH-sensitive when tested with 0.05 M NaOH and recorded a change from light violet to yellow-colorless. Two observers recorded no change.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *Streptomyces griseoruber*, AB184209, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1590, ATCC 23617, ATCC 25440, CBS 671.69, DSM 40467, NBRC 13028, INA 1242, JCM 4463, NRRL B-12382, NRRL-ISP 5467, PCM 2311, RIA 1220, VKM Ac-1904.

Sequence accession no. (16S rRNA gene): AB184266.

116. **Streptomyces cinnamonensis** Okami *in* Maeda, Okami, Kosaka, Taya and Umezawa 1952, 572[AL]

cin.na.mo.nen′sis. L. n. *cinnamum* cinnamon; N.L. masc. adj. *cinnamonensis* belonging to cinnamon, referring to the color of the aerial mycelium.

Spore chains of typical *Retinaculum-Apertum* type; spores phalangiform. NaCl tolerance >4%, but <7%. Produces actihiazic acid, a biotin antagonist and anti-mycobacterial antibiotic; exhibits anti-fungal activity.

Type strain shows the highest sequence similarity to: *S. pseudoechinosporeus*, AB184100, 99.9%; *S. hiroshimensis*, AB184789, 99.7%; *S. blastmyceticus*, AY999802, 99.3%; *S. caeruleus*, EF178675, 99.3%; *S. aureoversilis*, AB184855, 99.2%; *S. werraensis*, DQ442558, 99.1%; *S. lilacinus*, AB184819, 99.1%; *S. abikoensis*, AB184537, 99.1%; *S. ardus*,

117. **Streptomyces cinnamoneus** (Benedict, Dvonch, Shotwell, Pridham and Lindenfelser 1952) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Streptomyces cinnamoneus*" Benedict, Dvonch, Shotwell, Pridham and Lindenfelser 1952, 591; "*Streptomyces cinnamomeus* forma *cinnamomeus*" (*sic*) Pridham, Shotwell, Stodola, Lindenfelser, Benedict and Jackson 1956, 576; "*Streptoverticillium cinnamomeus* forma *cinnamomeus*" (*sic*) Baldacci 1958, 25; "*Verticillomyces cinnamomeus* forma *cinnamomeus*" (*sic*) Shinobu 1965, 104; *Streptoverticillium cinnamoneum* Baldacci, Farina and Locci 1966, 158]

cin.na.mo′ne.us. L. n. *cinnamum* cinnamon; N.L. adj. *cinnamoneus* cinnamon-colored (after the color of the aerial mycelium).

Spore chains in *Umballate Monoverticillate* (= *Streptomyces* section *Verticillati*, biverticillate). Mature spore chains generally have 3–10, often more than 10, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayish yellow to yellow-brown or brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Vegetative growth is generally poor on Pridham and Gottlieb's carbon utilization medium plus D-glucose. Reports form collaborators vary from no growth to slight growth with other carbon sources, but good growth is not observed on any of the following: L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, or raffinose. Poor growth on all carbon sources including D-glucose may indicate a requirement for a growth factor not present in the basal medium.

Type strain shows the highest sequence similarity to: *S. cinnamoneus*, X53171, 99.8%; *S. cinnamoneus*, X53165, 99.6%; *S. olivoreticuli*, X53166, 99.6%; *S. cinnamoneus* subsp. *albosporus* DSM 40897^T, 99.6%; *S. cinnamoneus* subsp. *lanosus* DSM 40898^T, 99.6%; *S. cinnamoneus* subsp. *sparsus* DSM 40899^T, 99.6%; *S. roseoverticillatus* DSM 40845^T, 99.6%; *S. olivoreticuli* subsp. *cellulophilus*, X53166, 99.5%; *S. lavendofoliae* DSM 40217^T, 99.5%; *S. parvisporogenes*, DSM 40473^T, 99.5%; *S. baldacii*, X53164, 99.4%; *S. albireticuli*, DSM 40051^T, 99.4%; *S. alboverticillatus*, DSM 41678^T, 99.4%; *S. hiroshimensis*, DSM 40037^T, 99.4%; *S. lilacinus*, DSM 40254^T, 99.4%; *S. blastmyceticus*, DSM 40029^T, 99.3%; *S. gobitricini*, DSM 41701^T, 99.3%; *S. lavendulocolor*, DSM 40216^T, 99.3%; *S. septatus*, DSM 40577^T, 99.3%; *S. eurocidicus*, DSM 40604^T, 99.2%; *S. kashmirensis*, DSM 40336^T, 99.2%; *S. luridus*, DSM 40081^T, 99.2%; *S. kasugaensis*, AB024441, 99.1%; *S. kasugaensis*, AB024442, 99.1%; *Streptomyces* sp., AF012739, 99.1%; *S. salmonis*, X53169, 99.1%; *S. baldacii*, X53164, 99.1%; *S. roseoverticillatus*, X53164, 99.1%; *S. griseoruber*, DSM 40181^T, 99.1%; *S. luteoverticillatus*, DSM 40038^T, 99.1%; *S. celluloflavus*, DSM 40839^T, 99.1%; *S. ehimensis*, DSM 40253^T, 99.1%; *S. mauvecolor*, DSM 41702^T, 99.1%; *S. melanogenes*, DSM 40192^T, 99.1%; *S. michiganensis*, DSM 40015^T, 99.1%; *S. noboritoensis*, DSM 40223^T, 99.1%; *S. roseofulvus*, DSM 40172^T, 99.1%; *S. roseolus*, DSM 40174^T, 99.1%; *S. sapporonensis*, DSM 41675^T, 99.1%; *S. viridoflavum*, DSM 40237^T, 99.1%; *S. xanthochromogenes*, DSM 40111^T, 99.1%; *S. alanosinicus*, DSM 40606^T, 99%; *S. ardus*, DSM 40527^T, 99%; *S. aureoversile*, DSM 40387^T, 99%; *S. filamentosus*, DSM 40022^T, 99%; *S. griseoverticillatus*, DSM 40507^T, 99%; *S. hachijoensis*, DSM 40114^T, 99%; *S. netropsis*, DSM 40259^T, 99%; *S. roseosporus*, DSM 40122^T, 99%; *S. thioluteus*, DSM 40027^T, 99%; *S. varsoviensis*, DSM 40346^T, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 11874, AS 4.1084, AS 4.1706, ATCC 23897, CBS 293.64, CBS 683.68, BCRC 12169, CCUG 11122, CECT 3258, DSM 40005, HAMBI 1067, NBRC 12852, IMET 41381, JCM 4152, JCM 4633, LMG 5971, NCIMB 8851, NRRL B-1285, NRRL-ISP 5005, RIA 1102, RIA 360, VKM Ac-876.

Sequence accession no. (16S rRNA gene): AB184850.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), on Validation List no. 38, *Streptomyces cinnamoneus* is proposed as a *nomen revictum* (basonym: "*Streptomyces cinnamoneus*" Benedict et al. 1952).

Witt and Stackebrandt proposed to transfer *Streptoverticillium cinnamoneum* (Benedict et al. 1952) Baldacci et al. 1966 to the genus *Streptomyces* as *Streptomyces cinnamoneus* (Benedict et al. 1952) Witt and Stackebrandt 1991. However, Validation List no. 38 does not include formal propositions about *Streptoverticillium cinnamoneum* subsp. *albosporum* Thirumalachar 1968, *Streptoverticillium cinnamoneum* subsp. *cinnamoneum* (Benedict et al. 1952) Baldacci et al. 1966, *Streptoverticillium cinnamoneum* subsp. *lanosum* Thirumalachar 1968 and *Streptoverticillium cinnamoneum* subsp. *sparsum* Thirumalachar 1968.

According to Hatano et al. (2003), *Streptomyces cinnamoneus* (Benedict et al. 1952) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces griseoverticillatus* (Shinobu and Shimada 1962) Witt and Stackebrandt 1991, of *Streptomyces hachijoensis* (Hosoya et al. 1952) Witt and Stackebrandt 1991, and of *Streptomyces sapporonensis* (Locci and Schofield 1989) Witt and Stackebrandt 1991.

118. **Streptomyces cirratus** Koshiyama, Okanishi, Ohmori, Miyake, Tsukiura, Matsuzaki and Kawaguchi 1963, 65[AL]

cir.ra′tus. L. masc. adj. *cirratus* curled, having ringlets.

Spore chains in Section *Retinaculiaperti*. Spore chains often with terminal loops, primitive spirals, or sometimes well-defined coils of several turns. Mature spore chains are

generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Special morphological characteristics: knots and moist, nest-like tangles may be seen in long aerial hyphae or moist droplets may form around terminal coils.

Color of colony: aerial mass color usually in the Red color series (5dc or 5cb, grayish yellowish pink, or 5ge, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; aerial mycelium sometimes is in the Gray color series (5fe, light grayish reddish brown) on these media. Reverse side of colony with no distinctive pigments (grayish yellow to light yellowish brown on yeast-malt agar; nearly colorless, pale grayish yellow, or light olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are usually formed in peptone-yeast-iron agar and tryptone-yeast broth, but are formed weakly or not at all in tyrosine agar. Yellow pigment is usually found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, and D-fructose are utilized for growth. No growth or only traces of growth with iso-inositol, D-mannitol, rhamnose, sucrose, or raffinose.

Type strain shows the highest sequence similarity to: *S. vinaceus*, AB184394, 100%; *S. spororaveus*, AJ781370, 99.9%; *S. nojiriensis*, AJ781355, 99.9%; *S. xanthophaeus*, DQ442560, 99.8%; *S. sporoverrucosus*, DQ442544, 99.7%; *S. goshikiensis*, EF178693, 99.7%; *S. cinnamonensis*, AB184707, 99.6%; *S. avidinii*, AB184395, 99.6%; *S. colombiensis*, DQ026646, 99.6%; *S. subrutilus*, X80825, 99.5%; *S. virginiae*, D85119, 99.4%.

119. **Streptomyces ciscaucasicus** Sveshnikova 1986, 574[VP] (Effective publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

cis.cau.ca.si′cus. N.L. masc. adj. *ciscaucasicus* of or pertaining to Ciscaucasus.

Spore chains are spiral (*Spirales*); spores are spiny, spines are medium sized. On mineral agar 1, glycerol-nitrate agar, and oatmeal agar: aerial mycelium is light gray, gray; substrate mycelium is yellowish red to red; no diffusible pigment. On starch-ammonia agar: aerial mycelium is gray, sometimes with brown shadow; substrate mycelium is red with yellowish or brownish shadow; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is light gray to gray; substrate mycelium is brownish red, raspberry red; no diffusible pigment. On organic agar 2: aerial mycelium is white to light gray; substrate mycelium is yellowish, reddish, yellowish reddish, light gray-brownish red; no diffusible pigment. Melanoid pigments are not formed. Good growth on glucose, arabinose, sucrose, xylose, fructose, rhamnose, raffinose, and mannitol. Produces antibiotic pigment of the prodigiosin group. Pigment of substrate mycelium can act as an indicator: yellow under alkaline reaction; dark pink to pinkish red under acidic reaction.

Type strain shows the highest sequence similarity to: *S. canus*, AY999775, 99.8%; *S. pseudovenezuelae*, AB184233, 99.2%; *S. resistomycificus*, AB184166, 99.1%.

Sequence accession no. (16S rRNA gene): AY508512.

120. **Streptomyces citreofluorescens** (Korenyako, Krasil'nikov, Nikitina and Sokolova 1960) Pridham 1970, 10[AL] ("*Actinomyces citreofluorescens*" Korenyako, Krasil'nikov, Nikitina and Sokolova *in* Rautenshtein 1960, 156)

cit.re.o.flu.o.res′cens. L. n. *citrus* the citrus, the citrontree; N.L. v. *fluoresco* fluoresce; N.L. part. adj. *citreofluorescens* with a yellow fluorescence.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (light yellow or grayish yellow to light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow pigment is found in medium in glycerol-asparagine agar and yellow or green pigment is found in medium in yeast-malt agar, oatmeal agar, and salts-starch agar. This pigment is not a pH indicator.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, or raffinose.

For sequence similarity, see type strain of *Streptomyces anulatus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1604, CBS 101.27, DSM 40843, NBRC 15398, JCM 5059, NRRL B-2557.

Sequence accession no. (16S rRNA gene): DQ026670.

122. **Streptomyces clavuligerus** Higgens and Kastner 1971, 330[AL]

cla.vu.li.ge′rus. L. fem. n. *clavula* little club; N.L. suff. *-gerus* bearing; N.L. masc. adj. *clavuligerus* bearing little clubs.

Produces aerial mycelium which is composed of a network of sympodially branched, aerial hyphae that eventually segment into spores. Short, clavate, side branches are formed that usually produce from one to four spores each. Spore chain morphology is classified in the *Rectus-flexibilis* section. Spores are oblong to short-cylindrical averaging 0.64 by 1.53 μm in size, with smooth spore surfaces. Neither fragmentation of hyphae nor formation of spores occurs in the substrate mycelium.

Aerial mycelium is dark grayish green on media with abundant sporulation. The color ranges from white to gray, to light grayish white on other media. Substrate mycelia vary from pale yellow to grayish yellow. No soluble pigment is produced on any of the 11 media used. The culture is assigned to the Gray (GY) and Green (GN) series of Tresner and Backus. The Maerz and Paul (1950) color block most similar to the spore color en masse is 21-B1, and the light grayish olive color of the ISCC-NBS designation method corresponds to this color block. The culture grows over the pH range 5.0–8.5. Growth does not occur at pH 4.0 or 9.0. Sporulation occurs from pH 5.0 to 6.5 and is most abundant at pH 6.0. Whole-cell hydrolysates contain LL-A_2pm, glycine, aspartic acid, alanine, glutamic acid and leucine as major constituents.

Type strain shows no sequence similarity over 99%.

Source: soil.

DNA G+C content (mol%): not known.

Type strain: AS 4.1611, ATCC 27064, CBS 226.75, BCRC 11518, CECT 3125, DSM 40751, DSM 738, NBRC 13307, IMET 43657, JCM 4710, KCTC 9095, NCIMB 12785, NRRL 3585, VKM Ac-602.

Sequence accession no. (16S rRNA gene): AY 999718.

123. **Streptomyces coelescens** (Krasil'nikov, Sorokina, Alferova and Bezzubenkova *in* Krasil'nikov 1965) Pridham 1970, 21[AL] ("*Actinomyces coelescens*" Krasil'nikov, Sorokina, Alferova and Bezzubenkova *in* Krasil'nikov 1965, 110)

co.e.les′cens. N.L. adj. *coelescens* slightly blue.

Spore chains in Section *Spirales*; spirals are best developed on salts-starch agar or oatmeal agar. Flexuous chains and imperfect spirals suggesting *Retinaculiaperti* morphology are also common on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Mature spore chains are moderately long with 10–50 spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray; 2dc, yellowish gray or 3ge light grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is dark grayish purple or blackish purple on salts-starch agar and glycerol-asparagine agar; grayish brown to dark brown or reddish black on yeast-malt agar and oatmeal agar. Reverse mycelium pigment is a pH indicator, changing from reddish violet to bluish violet or blue with the addition of 0.05 M NaOH and from bluish violet to reddish violet, brown, or red with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red, violet, or blue pigment, depending on pH, may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar, but pigment is not always found in these media. This pigment is pH-sensitive, showing essentially the same changes noted for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of sucrose or raffinose is doubtful.

Type strain shows the highest sequence similarity to: *S. humiferus*, AF503491, 100%; *S. violaceolatus*, AF503497, 100%; *S. violaceoruber*, AF503492, 100%; *S. tricolor*, AB184687, 99.9%; *S. anthocyanicus*, AB184631, 99.9%; *S. rubrogriseus*, AB184681, 99.7%; *S. tendae*, D63873, 99.6%; *S. lienomycini*, AJ781353, 99.6%; *S. violaceorubidus*, AJ781374, 99.4%; *S. coelicoflavus*, AB184650, 99.3%; *S. ambofaciens*, M27245, 99%; *S. pactum*, AB184398, 99%.

DNA G+C content (mol%): not known.
Type strain: AS 4.1596, DSM 41471, NBRC 15399, INA 9630, JCM 6918, NRRL B-16363, VKM Ac-1221.
Sequence accession no. (16S rRNA gene): AB184650.

125. **Streptomyces coelicolor** (Müller 1908) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 935[AL] ("*Streptothrix coelicolor*" Müller 1908, 197; "*Cladothrix coelicolor*" Macé 1913, 758; "*Nocardia coelicolor*" Chalmers and Christopherson 1916, 271; "*Actinomyces coelicolor*" Lieske 1921, 28; "*Corynebacterium coelicolor*" Müller 1950, 274)

co.e.li.co′lor. L. n. *caelum* heaven, sky (blue); L. n. *color* color; N.L. n. *coelicolor* (*sic*) sky (blue) color.

Spore chains in Section *Rectiflexibliles*. Mature spore chains usually have 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Special morphological characteristics: one observer reports substrate conidia on oatmeal agar, Emerson's potato glucose agar, and potato carrot agar. Sclerotia formation on yeast-malt agar and oatmeal agar was reported by one observer.

Color in colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is light olive brown to strong brown or very dark brown on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; brown substrate mycelium pigment on oatmeal agar is pH-sensitive changing from brown to green with addition of 0.05 M NaOH. Potato plug is pigmented dark blue in 4–7 d.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Reddish yellowish brown or greenish pigments are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; yellowish brown pigment is changed to green with addition of 0.05 M NaOH. Liquid surrounding dark blue potato plug is pigmented greenish brown in 4–7 d.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. aurantiogriseus*, AY999793, 99.9%; *S. griseoviridis*, AY999807, 99.3%.

Type strain: AS 4.1658, ATCC 23899, CBS 210.27, CBS 795.68, BCRC 12067, CCUG 11110, DSM 40233, NBRC 12854, JCM 4357, NCIMB 9798, NRRL B-2812, NRRL-ISP 5233, PCM 2324, RIA 1173, VKM Ac-738.
Sequence accession no. (16S rRNA gene): DQ442496.

126. **Streptomyces coeruleoflavus** Preobrazhenskaya and Maximova 1986, 574[VP] (Effective publication: Preobrazhenskaya and Maximova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

co.e.ru.le.o.fla′vus. L. adj. *caeruleus* dark blue, azure; L. adj. *flavus* yellow; N.L. masc. adj. *coeruleoflavus* (*sic*) dark blue, yellow.

Spore chains are spiral (*Spirales*); spores are spiny; spines are medium-sized. On mineral agar 1: aerial mycelium is smooth, color is gray to light blue; substrate mycelium is yellow, dark orange, or brown-yellow; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is light blue; substrate mycelium and diffusible pigment are yellow-brown to brown. On starch-ammonia agar: aerial mycelium is light blue; substrate mycelium is brown-yellow to brown; diffusible pigment is yellow-gray. On glycerol-asparagine agar: aerial mycelium and diffusible pigment are not found; substrate mycelium is colorless. On oatmeal agar: aerial mycelium is light blue; substrate mycelium and diffusible pigment are dark brown. Melanoid pigments are not formed. Good growth on rhamnose, glucose, mannitol, sucrose, arabinose, xylose, fructose, inositol, and raffinose. Antibiotic: actinomycin D.
Source: not known.
DNA G+C content (mol%): not known.

Type strain: INA 2206.

Sequence accession no. (16S rRNA gene): no sequence available.

127. **Streptomyces coeruleofuscus** (Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces coeruleofuscus*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 128)

co.e.ru.le.o.fus′cus. L. adj. *caeruleus* dark blue, azure; L. adj. *fuscus* dark, tawny; N.L. masc. adj. *coeruleofuscus* (*sic*) dark blue, tawny (referring to the bluish aerial mycelium and brownish vegetative mycelium of the organism).

Spore chains in Section *Spirales*. Mature spore chains are long, often more than 50 spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Blue color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is variable in color; it is yellow-brown modified by red on yeast-malt agar and characteristic grayed yellow or grayed greenish yellow (center of growth) modified by green, red, and brown (borders) on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate is not a pH indicator; however, one observer reports that on glycerol-asparagine agar, the reverse color is changed from olive green to bluish green by addition of 0.05 M NaOH, and from olive green to very pale red with HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tryptone-yeast broth, and some other media. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. cinereospinus*, AB184648, 99.2%; *S chromofuscus*, AB184194, 99.1%.

Sequence accession no. (16S rRNA gene): DQ026668.

128. **Streptomyces coeruleoprunus** Preobrazhenskaya 1986, 574[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

co.e.ru.le.o.pru′nus. L. adj. *caeruleus* dark blue, azure; L. n. *prunum* plum; N.L. masc. adj. *coeruleoprunus* (*sic*) dark blue plum.

Spore chains are straight (*Rectiflexibiles*); spores are smooth. On mineral agar 1: aerial mycelium is smooth, color is gray to light blue; substrate mycelium is brown-violet to blue-black or brown-yellow; diffusible pigment is brown-pink to brown. On oatmeal agar: aerial mycelium is light blue; substrate mycelium and diffusible pigment are pink to gray-violet. On starch-ammonia agar: aerial mycelium is light blue; substrate mycelium is colorless to brown; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium color is light to pale blue; substrate mycelium is colorless; no diffusible pigment. On organic agar 2: white to light blue aerial mycelium; substrate mycelium and diffusible pigment are dark gray-brown or brown. Melanoid pigments are not formed. Good growth on glucose, sucrose, rhamnose, mannitol, arabinose, xylose, fructose, inositol, and raffinose. Antibiotic: neomycin.

Type strain shows the highest sequence similarity to: *S. fradiae*, DQ026630, 99.2%; *S. somaliensis*, AJ007403, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1648, ATCC 43681, DSM 41472, NBRC 15400, INA 1655, JCM 6919, NRRL B-16364, VKM Ac-1208.

Sequence accession no. (16S rRNA gene): AB184651.

129. **Streptomyces coeruleorubidus** (Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces coeruleorubidus*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 125)

co.e.ru.le.o.ru′bi.dus. L. adj. *caeruleus* dark blue, azure; L. adj. *rubidus* dark red; N.L. masc. adj. *coeruleorubidus* (*sic*) dark blue, dark red (referring to the bluish aerial mycelium and red vegetative mycelium of the organism on chemically defined media).

Spore chains in Section *Spirales*. Salts-starch agar shows best spiral morphology; incomplete spirals and hooks may also be common, especially on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. Mature spore chains generally have 10–50 spores per chain. Spore surface is spiny.

Color of colony: aerial mass color is in the Blue color series on oatmeal agar and salts-starch agar; Blue or White color series on yeast-malt agar and glycerol asparagine agar. Reverse side of colony is grayish yellow to yellowish brown on yeast-malt agar; grayed yellow to yellowish green on oatmeal agar and salts-starch agar; both grayed yellowish green and grayed red or orange on glycerol-asparagine agar. These substrate mycelium pigments are not pH indicators when tested with 0.05 M NaOH or HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Red pigment may be found in medium in yeast-malt agar, salts-starch agar, and glycerol-asparagine agar after 14 d; it is not pH-sensitive.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

131. **Streptomyces collinus** Lindenbein 1952, 380[AL]

col.li′nus. L. masc. adj. *collinus* hilly, mounded.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Spore chains are short resulting in poorly developed spirals of only a few turns; loops and hooks are of small diameter and therefore are not representative of true *Retinaculiaperti* cultures. Distinct spore chains are relatively short, often with only 3–10 spores per chain; longer chains occur, but often coalesce as masses of spores. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. After 14 d, subglobose bodies, composed primarily of masses of spores, can be seen. They appear to originate at the hooked or spiral ends of *Retinaculiaperti* spore chains and to be held together by fluid.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; or (by one observer) in the Red series on salts-starch agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and sometimes in tryptone-yeast broth, but not on tyrosine agar. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. Two of three observers found good growth with D-xylose.

Type strain shows the highest sequence similarity to: *S. violaceochromogenes*, AY999867, 99.6%; *S. paradoxus*, AB184628, 99.5%; *S. griseoflavus*, AJ781322, 99.5%; *S. viridochromogenes*, DQ442555, 99.3%; *S. iakyrus*, AB184877, 99.3%; *S. matensis*, AB184221, 99.2%; *S. ambofaciens*, M27245, 99.2%; *S. flaveolus*, AB184764, 99.2%; *S. griseorubens*, AB184139, 99.2%; *S. erythrogriseus*, AJ781328, 99.1%; *S. griseoincarnatus*, AJ781328, 99.1%; *S. variabilis*, DQ442551, 99.1%; *S. labedae*, AB184704, 99.1%; *S. violaceorubidus*, AJ781374, 99%.

Source: not known.

Type strain: AS 4.1623, ATCC 19743, CBS 482.68, BCRC 11465, DSM 2012, DSM 40129, ICMP 12539, NBRC 12759, JCM 4361, KCTC 9713, NRRL B-5412, NRRL-ISP 5129, RIA 1024, UNIQEM 130, VKM Ac-710.

Sequence accession no. (16S rRNA gene): AB184123.

132. **Streptomyces colombiensis** Pridham, Hesseltine and Benedict 1958, 76[AL] emend. Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2004, 88.)

co.lom.bi.en′sis. N.L. masc. adj. *colombiensis* of or belonging to Columbia.

Spore chains in Section *Spirales.* Flexuous spore chains and open loops resembling *Retinaculiaperti* morphology are also present. Mature spore chains are generally long with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5dc, 5ec, 5cb, 6ec, grayish yellowish pink; or 5ge, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is moderate reddish orange to strong brown on yeast-malt agar; grayish yellow, orange yellow, or yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in tyrosine agar; reports vary on production of melanoid pigments in peptone-yeast-iron agar and tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and D-fructose are utilized for growth. No growth or only traces of growth with L-arabinose, D-xylose, iso-inositol, D-mannitol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. goshikiensis*, EF178693, 100%; *S. sporoverrucosus*, DQ442544, 99.9%; *S. nojiriensis*, AJ781355, 99.8%; *S. spororaveus*, AJ781370, 99.8%; *S. xanthophaeus*, DQ442560, 99.7%; *S. vinaceus*, AB184394, 99.7%; *S. cirratus*, AY999794, 99.6%; *S. cinnamonensis*, AB184707, 99.5%; *S. avidinii*, AB184395, 99.5%; *S. subrutilus*, X80825, 99.3%; *S. virginiae*, D85119, 99.1%.

Source: not known.

Type strain: ATCC 27425, CBS 755.72, DSM 40558, NBRC 13454, JCM 4675, JCM 4740, NRRL B-1990, NRRL-ISP-5558, RIA 739, RIA 1415.

Sequence accession no. (16S rRNA gene): DQ026646.

Further comments: according to Lanoot et al. (2004), *Streptomyces colombiensis* Pridham et al. 1958 is an earlier heterotypic synonym of *Streptomyces distallicus* (Locci et al. 1969) Witt and Stackebrandt 1991.

133. **Streptomyces corchorusii** Ahmad and Bhuiyan 1958, 143[AL] emend. Lanoot, Vancanneyt, Van Shoor, Liu and Swings 2005b, 731

cor.cho.ru′si.i. L. n. *Corchorus* name of a plant and a scientific generic name; L. gen. n. *corchorusii* (*sic*) of Corchorus, because the organism was isolated from soil of a field of jute, *Corchorus capsulatus.*

Spore chains in Section *Spirales* to *Rectiflexibiles.* Incomplete spirals (hooks) and flexuous or straight spore chains are common; spirals usually have only 1–3 turns. Hooks and primitive spirals are on relatively short chains and are therefore not representative of typical *Retinaculiaperti* or *Rectiflexibiles* morphology. Mature spore chains generally have 10–20 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Electron micrographs show spores of irregular size and shape; some surface irregularities may be present.

Color of colony: aerial mass color in the Gray color series (color tabs 3ge, light grayish yellowish brown and 3fe or 4li, brownish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (yellow to yellowish brown or olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment (or only a trace of yellow) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. olivaceoviridis*, AB184288, 99.9%; *S. canarius*, AB184396, 99.8%; *S. capoamus*, AB045877, 99.5%; *S. longwoodensis*, AB184580, 99.4%; *S. bungoensis*, AB184696, 99.4%; *S. galbus*, X79852, 99.3%; *S. griseochromogenes*, AB184387, 99%; *S. cellostaticus*, AB184192, 99%.

Source: isolated from soil from a field of jute.

DNA G+C content (mol%): not known.

Type strain: AS 4.1592, ATCC 25444, CBS 677.69, BCRC 11821, DSM 40340, NBRC 13032, JCM 4286, JCM 4467, KCTC 9715, LMG 20488, NCIMB 9476, NCIMB 9979, NRRL B-12289, NRRL-ISP 5340, RIA 1224, VKM Ac-1906.

Sequence accession no. (16S rRNA gene): AB184267.

Further comments: according to Lanoot et al. (2005b), *Streptomyces corchorusii* Ahmad and Bhuiyan 1958 emend. Lanoot et al. 2005b is an earlier heterotypic synonym of *Streptomyces chibaensis* Suzuki et al. 1958.

According to Rule 24b of the *Bacteriological Code* (1990 Revision), if two names compete for priority and if both names are listed on the Approved Lists of Bacterial Names, the priority shall be determined by the date of the effective publication of the name before 1 January 1980. S*treptomyces chibaensis* and *Streptomyces corchorusii* are cited in the Approved Lists. The dates of effective publications are 1958. Consequently, to determine priority it is necessary to know the month (and perhaps the day) of the effective publications. *Streptomyces chibaensis* was effectively published in the *Journal of Antibiotics* (*Tokyo*) *Series A*, 1958, vol. 11, pp. 81–83, and *Streptomyces corchorusii* in the *Pakistan Journal of Biological and Agricultural Sciences*, 1958, vol. 1, pp. 137–143. It is certainly not easy to know the exact dates of publication of these articles. However, according to Rule 42 of the *Bacteriological Code* (1990 Revision), if the epithets are of the same date, the author who first unites the taxa has the right to choose one of them, and his choice must be followed. Lanoot et al. chose the epithet *corchorusii.*

134. **Streptomyces costaricanus** Esnard, Potter and Zuckerman 1995, 778[VP]

cos.ta.ri.can′us. N.L. adj. masc. *costaricanus* of or belonging to Costa Rica, the geographic origin of the organism.

Mature spore chains are tightly coiled spirals with 10–50 spores per chain. Spores are smooth and gray-brown in mature colonies. Aerial mycelial mass is grayish brown on yeast extract-malt extract agar, oatmeal agar, inorganic salts-starch agar, and glycerol-asparagine agar and yellow on NZamine medium containing soluble starch and glucose (ATCC medium 172). The substrate mycelium is light yellow on yeast extract-malt extract agar and glycerol-asparagine agar, golden on ATCC medium 172, brown on oatmeal agar, and yellow on inorganic salts-starch agar. A yellow pH-insensitive diffusible pigment is produced on yeast extract-malt extract agar and glycerol-asparagine agar. The pigment color is yellow-orange on ATCC medium 172. No melanoid pigment is produced on peptone-yeast extract-iron agar or tyrosine agar. Color of the reverse side of the colonies is also not sensitive to pH.

D-Fructose, D-glucose, D-mannitol, D-xylose, salicin, and galactose are utilized for growth, but L-arabinose, raffinose, rhamnose, and sucrose are not utilized. Acid is produced from cellobiose, D-glucose, glycerol, maltose, galactose, D-mannitol, and D-xylose but not from L-arabinose, D-fructose, lactose, or sucrose. No growth occurs in the presence of ribitol, galactitol, erythritol, or iso-inositol; 7% NaCl is inhibitory. Cell walls contain LL-A_2pm. The most abundant hydrolyzable fatty acids are $C_{15:0}$ anteiso, $C_{16:0}$, $C_{17:0}$ anteiso, $C_{15:0}$ iso, $C_{16:0}$ iso, and $C_{17:0}$ iso in cells grown on ISP medium 2 agar. The concentration of octadecanoic acid is ninefold higher in ISP medium 2 broth.

Exhibits anti-nematodal activity against *Caenorhabditis elegans* and antibiotic activity against *Rhizoctonia solani* and *Phytium aphanidermatum.*

Type strain shows the highest sequence similarity to: *S. griseofuscus*, AB184206, 100%; *S. murinus*, AB184155, 100%; *S. phaeogriseichromatogenes*, AJ391813, 99.6%.

Source: isolated from a tropical soil.

DNA G+C content (mol%): not known.

Type strain: CR-43, ATCC 55274, DSM 41827, NRRL B-16897, JCM 11306, NBRC 100773, NCIMB 13455.

Sequence accession no. (16S rRNA gene): AB249939.

135. **Streptomyces cremeus** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 66[AL] (“*Actinomyces cremeus*” Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 93)

cre′me.us. N.L. masc. adj. *cremeus* cream-white.

Spore chains in Section *Retinaculiaperti*, but with many straight to flexuous spore chains. Open coils and primitive spirals are common. In the original description (Kudrina, ibid), this is characterized as a spiral culture. Mature spore chains are long, often with more than 50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt and salts-starch agar; Yellow series on glycerol-asparagine agar; Yellow or Red series on oatmeal agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate is not a pH indicator (one observer reports slight change from pale yellow to pale pink with 0.05 M NaOH).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. No pigments or only traces of yellow pigments in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. spiroverticillatus*, AB184814, 99.7%; *S. celluloflavus*, AB184476, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. candidus*, DQ026663, 99.2%; *S. sindenensis*, AB184759, 99.1%; *S. pluricolorescens*, DQ442540, 99.1%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.1%; *S. floridae*, AB184656, 99.1%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.1%; *S. mediolani*, AB184674, 99.1%; *S. rubiginosohelvolus*, AB184240, 99.1%; *S. argenteolus*, AB045872, 99.1%; *S. badius*, AY999783, 99.1%; *S. griseinus*, AB184205, 99.1%; *S. anulatus*, DQ026637, 99%; *S. flavogriseus*, AJ494864, 99%; *S. halstedii*, EF178695, 99%; *S. cyaneofuscatus*, AB184860, 99%; *S. parvus*, DQ442537, 99%; *S. albovinaceus*, AB249958, 99%; *S. californicus*, AB184755, 99%; *S. graminofaciens*, AJ781329, 99%; *S. alboviridis*, AB184256, 99%; *S. globisporus* subsp. *globisporus*, EF178686, 99%; *S. lipmanii*, AB184148, 99%; *S. microflavus*, DQ445795, 99%; *S. fulvorobeus*, AB184711, 99%; *S. griseoplanus*, AY999894, 99%; *S. flavovirens*, DQ026635, 99%; *S. praecox*, AB184293, 99%; *S. flavofuscus*, AB249935, 99%; *S. pulveraceus*, AB184806, 99%; *S. griseolus*, AB184768, 99%; *S. fimicarius*, AY999784, 99%; *S. cinereorectus*, AB184646, 99%.

Type strain: AS 4.1625, ATCC 19744, ATCC 19897, CBS 483.68, BCRC 11466, DSM 40147, NBRC 12760, IMET 43743, INA 815/54, JCM 4362, NCIMB 10030, NCIMB 9596, NRRL 3241, NRRL B-2583, NRRL-ISP 5147, RIA 1025, UNIQEM 131, VKM Ac-1844.

Sequence accession no. (16S rRNA gene): AB184124.

136. **Streptomyces crystallinus** Tresner, Davies and Backus 1961, 74[AL]

crys.tal.lin′us. L. masc. adj. *crystallinus* made of crystal, crystalline, referring to crystals formed by the organism in some media.

Spore chains are straight to long and flexuous; forms light to dark brown vegetative mycelium and diffusible pigment on many media. Poor growth on Czapek’s solution agar; produces hygromycin A and other antibiotics; exhibits anti-fungal activity; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. melanogenes*, AB184222, 99.2%; *S. noboritoensis*, AB184287, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.16, DSM 40945, NBRC 15401, JCM 5067, KCTC 9717, NCIMB 12860, NRRL B-3629.

Sequence accession no. (16S rRNA gene): AB184652.

137. **Streptomyces curacoi** Cataldi *in* Trejo and Bennett 1963, 683[AL]

cu.ra′co.i. N.L. gen. n. *curacoi* of Cura-Co in the province of La Pampa, Argentina.

Spore chains in Section *Spirales.* Mature spore chains generally have 10–50 spores per chain; long chains are not common. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but formation of sporulating aerial mycelium is not uniformly good in different laboratories with this strain. Spore surface is spiny.

Color of colony: aerial mass color in the Blue color series on salts-starch agar and on other media (yeast-malt agar, oatmeal agar, glycerol-asparagine agar) when mature spores occur; immature spore chains or non-sporulation aerial mycelium appears white. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. Trace of growth is seen on rhamnose or raffinose.

Type strain shows the highest sequence similarity to: *S. longwoodensis*, AB184580, 99%; *S. capoamus*, AB045877, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: 5828, ATCC 13385, ATCC 19745, CBS 484.68, NBRC 12761, JCM 4219, JCM 4573, NRRL B-2901, NRRL-ISP 5107, RIA 1026, SC 3604, UNIQEM 132.

Sequence accession no. (16S rRNA gene): EF626595.

138. **Streptomyces cuspidosporus** Higashide, Hasegawa, Shibata, Mizumo and Akaike 1966, 2[AL]

cu.spi.do.spo′rus. L. n. *cuspis -idis* point; N.L. n. *spora* a spore; N.L. masc. adj. *cuspidosporus* spore with points or spines.

Forms green to blue to yellowish green diffusible pigment on some media. Excellent growth on Czapek's solution agar; produces sparsomycin, tubercidin, and several other antibiotics.

Type strain shows the highest sequence similarity to: *S. sparsogenes*, AB184301, 99.9%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1886, ATCC 33340, CBS 192.78, DSM 41425, DSM 41653, NBRC 12378, JCM 4316, KCTC 9718, NRRL B-5620, VKM Ac-599.

Sequence accession no. (16S rRNA gene): AB184090.

139. **Streptomyces cyaneofuscatus** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 58[AL] ("*Actinomyces cyaneofuscatus*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 85)

cy.a.ne.o.fus.ca′tus. L. adj. *cyaneus* dark blue; L. adj. *fuscus* dark, tawny; L. masc. suff. *-atus* suffix used with the sense of provided with; N.L. masc. adj. *cyaneofuscatus* provided with dark blue, tawny, referring to different pigments formed.

Spore chains are in Section *Rectiflexibiles.* Mature spore chains generally have 10–50 spores per chain. Typical morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Coremia may be formed on oatmeal agar, salts-starch agar, and tyrosine agar.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed from pale yellowish green to pink by addition of 0.05 M HCl or from pale yellow to yellowish green with NaOH.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar. Pigments other than a weak yellow pigment are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. On glucose-mineral salts medium (CPI Kuznetsov: glucose, 2%; KNO_3, 0.1%; $MgSO_4$, 0.05%; NaCl, 0.05%; K_2HPO_4, 0.05%; $CaCO_3$, 0.3%; agar, 2.0%), blue pigment is formed in the medium. Blue pigment is pH-sensitive, changing from blue to pink with 0.05 M HCl.

D-Glucose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. alboviridis*, AB184256, 99.9%; *S. fulvorobeus*, AB184711, 99.9%; *S. praecox*, AB184293, 99.9%; *S. anulatus*, DQ026637, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. microflavus*, DQ445795, 99.9%; *S. sindenensis*, AB184759, 99.8%; *S. rubiginosohelvolus*, AB184240, 99.8%; *S. mediolani*, AB184674, 99.8%; *S. griseinus*, AB184205, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. pluricolorescens*, DQ442540, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. badius*, AY999783, 99.8%; *S. floridae*, AB184656, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. globisporus* subsp. *globisporus*, EF178686, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. californicus*, AB184755, 99.7%; *S. parvus*, DQ442537, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. flavovirens*, DQ026635, 99.6%; *S. flavogriseus*, AJ494864, 99.5%; *S. olivoviridis*, AB184227, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. finlayi*, AY999788, 99.4%; *S. pulveraceus*, AB184806, 99.4%; *S. atroolivaceus*, AJ781320, 99.4%; *S. yanii*, AB006159, 99.4%; *S. clavifer*,

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1612, ATCC 19746, ATCC 23619, CBS 485.68, BCRC 11467, DSM 40148, NBRC 13190, IMET 41583, INA 99/54, JCM 4364, NCIMB 13021, NRRL B-2570, NRRL-ISP 5148, RIA 1027, UNIQEM 133, VKM Ac-752.

Sequence accession no. (16S rRNA gene): AB184860.

140. **Streptomyces cyaneus** (Krasil'nikov 1941) Waksman *in* Waksman and Lechevalier 1953, 42[AL] ("*Actinomyces cyaneus*" Krasil'nikov 1941, 14)

cy'a.ne.us. L. masc. adj. *cyaneus* dark blue.

Spore chains in Section *Spirales.* Compact spirals of 2–6 turns are common, but open spirals, imperfect spirals or flexuous spore chains may also be found. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Blue or Gray color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; and Gray color series on oatmeal agar. Aerial mycelium may be poorly developed and atypical on glycerol-asparagine agar. The most representative color tabs from the Blue color series are 19fe or dc, pale blue, and the most representative color from the Gray color series is tab e, medium gray. Reverse side of colony is dark grayish blue to dark grayish purple on yeast-malt agar, oatmeal agar, and salts-starch agar; this pigmentation sometimes fails to develop on glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator, changing from violet or purple to blue with the addition of 0.05 M NaOH and from blue to violet or purple with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Blue or violet pigment is found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar; it is often not formed in glycerol-asparagine agar. This pigment is pH-sensitive, showing the same changes noted for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. pseudovenezuelae*, AB184233, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1671, ATCC 14923, CBS 647.72, BCRC 13767, DSM 40108, NBRC 13346, JCM 4220, JCM 4743, KCTC 9719, NRRL B-16305, NRRL B-2296, NRRL-ISP 5108, PCM 2297, RIA 1307, VKM Ac-1712.

Sequence accession no. (16S rRNA gene): AF346475.

141. **Streptomyces cyanoalbus** (Krasil'nikov and Agre in Rautenshtein 1960) Pridham 1970, 13[AL] ("*Actinomyces cyanoalbus*" Krasil'nikov and Agre *in* Rautenshtein 1960, 273)

cy.a.no.al'bus. L. adj. *cyaneus* dark blue; L. adj. *albus* white; N.L. masc. adj. *cyanoalbus* blue, white, referring to formation of colorless (white) or blue vegetative mycelium.

Spore chains in Section *Spirales* or *Rectiflexibiles.* Distinct spirals are rare. Moderately short chains, often with only 10–20 spores, may form strongly wavy chains to open spirals of 1–4 turns. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: mature aerial mass color (14–21 d) is in the Green color series on yeast-malt agar and salts-starch agar; Green, Gray, or White color series on oatmeal agar and glycerol-asparagine agar. Aerial mycelium is usually poorly developed on oatmeal agar. Reverse side of colony is grayed yellow to grayed yellow-green on yeast-malt and oatmeal agar; grayed yellow-green to blue on salts-starch agar and glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on raffinose.

Type strain shows the highest sequence similarity to: *S. hirsutus*, AB184844, 100%; *S. bambergiensis*, AB184869, 99%; *S. prasinus*, DQ026658, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1426, ATCC 15859, ATCC 23902, CBS 798.68, DSM 40198, HAMBI 1045, NBRC 12857, INMI 414, JCM 4363, LMG 19343, NCIMB 9831, NRRL B-3040, NRRL-ISP 5198, RIA 1150, RIA 662, VKM Ac-585.

Sequence accession no. (16S rRNA gene): AB184882.

142. **Streptomyces daghestanicus** (Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces daghestanicus*" Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 59)

da.ghes.ta'ni.cus. N.L. masc. adj. *daghestanicus* of or belonging to Daghestan, A.S.S.R., the source of the soil from which the organism was isolated.

Spore chains in Section *Retinaculiaperti* but with some well defined spiral spore chains. Mature chains generally have 10–50 spores per chain. Typical morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth with some minor irregularities suggesting wartiness.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow to yellow-brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; the color is changed only slightly or not at all by addition of 0.05 M NaOH or HCl.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. canescens*, AB184117, 100%; *S. felleus*, AB184129, 100%; *S. limosus*, AB184147, 100%; *S. albidoflavus*, AB184255, 100%; *S. hydrogenans*, AB184868, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. sampsonii*, D63871, 99.8%; *S. koyangensis*, AY079156, 99.7%.

Source: isolated from soil from Daghestan, A.S.S.R.

DNA G+C content (mol%): not known.

Type strain: AS 4.169, ATCC 19747, ATCC 23620, CBS 486.68, BCRC 11468, DSM 40149, NBRC 12762, INA 2656/55, JCM 4365, NRRL B-5418, NRRL-ISP 5149, RIA 1028, UNIQEM 134, VKM Ac-1722, VKM Ac-1862.

Sequence accession no. (16S rRNA gene): DQ442497.

143. **Streptomyces demainii** Goodfellow, Kumar, Labeda and Sembiring 2008, 1[VP] (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 198.)

de.main′i.i. N.L. gen. masc. n. *demainii* of Demain, named in honor of Arnold Demain, a celebrated actinomycete biologist.

Spore chains in *Spirales*; spore surface is rugose. On oatmeal agar, the aerial spore mass color is gray, becoming black and moist when mature; the reverse side of colony growth is grayish-yellow. Melanin pigments are not formed.

Type strain shows the highest sequence similarity to: *S. sporocinereus*, AB249933, 99.9%; *S. hygroscopius* subsp. *hygroscopius*, AB184428, 99.9%; *S. endus*, AY999911, 99.9%; *S. violaceusniger*, AJ391823, 99.5%; *S. yogyakartensis*, AB249942, 99.5%; *S. albiflaviniger*, AJ391812, 99.3%.

Source: not known.

DNA G+C content (mol%): 71.2.

Type strain: DSM 41600, NRRL B-1478.

Sequence accession no. (16S rRNA gene): DQ334782.

144a. **Streptomyces diastaticus subsp. diastaticus** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 939[AL] ("*Actinomyces diastaticus*" Krainsky 1914, 687)

di.a.sta′ti.cus. N.L. masc. adj. *diastaticus* diastatic.

Spore chains in Section *Rectiflexibiles* to *Spirales*. Good spirals are not formed on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar, but highly flexuous or crooked spore chains, some of which suggest irregular spirals, are common on these media. Hooks, loops, or irregular spirals are of small diameter and are therefore not representative of true *Retinaculiaperti* morphology. Spore chains are often short, with 3–10 spores per chain, but longer chains are found. Spore surface is smooth.

Color of colony: sporulating aerial mycelium is often poorly developed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar so that aerial mass color is difficult to determine. When sporulating aerial mycelium is formed on these media, it may be in the Gray color series (2dc, yellowish gray) or the aerial color may appear to be in the Yellow color series (2ba, pale yellow; 1cb, pale yellowish green). Reverse side of colony with no distinctive pigments (grayish yellow or pale yellowish green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, sucrose, and D-mannitol are utilized for growth. No growth or only traces of growth with iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. gougerotii*, AB184742, 100%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 100%; *S. intermedius*, AB184277, 99.8%; *S. misionensis*, EF178678, 99.2%; *S. phaeoluteichromatogenes*, AJ391814, 99.1%; *S. matensis*, AB184221, 99%; *S. aureoverticillatus*, AY999774, 99%.

Source: not known.

Type strain: AS 4.1420, ATCC 3315, CBS 126.20, CBS 713.72, CCUG 11116, DSM 40496, NBRC 13412, NBRC 3714, IMET 40274, JCM 4128, JCM 4745, LMG 19322, NRRL B-1241, NRRL B-1270, NRRL-ISP 5496, RIA 104, RIA 1373, VKM Ac-723.

Sequence accession no. (16S rRNA gene): AB184785.

144b. **Streptomyces diastaticus subsp. ardesiacus** (Baldacci, Grein and Spalla 1955) Pridham, Hesseltine and Benedict 1958, 78[AL] ("*Actinomyces diastaticus* subsp. *ardesiacus*" Baldacci, Grein and Spalla 1955, 136)

ar.de.si′a.cus. N.L. masc. adj. *ardesiacus* (from Italian n. *ardesia* slate) intended to mean slate colored.

Excellent growth on Czapek's solution agar. Inhibited by streptomycin. Type strain shows the highest sequence similarity to: *S. coelicoflavus*, AB184650, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1682, CBS 100.56, DSM 40934, NBRC 15402, JCM 5815, NRRL B-1773.

Sequence accession no. (16S rRNA gene): DQ026631.

145. **Streptomyces diastatochromogenes** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 941[AL] ("*Actinomyces diastatochromogenes*" Krainsky 1914, 687)

di.a.sta.to.chro.mo′gen.es. Gr. adj. *diastatus* split, divided; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *diastatochromogenes* producing diastatic color, presumably intended to mean producing diastase and color.

Spore chains in Section *Spirales* (or *Retinaculiaperti*). Spirals are open with 4–6 turns, and strongly flexuous to straight spore chains are also common. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but aerial mycelium may be poorly developed or absent on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar; aerial mycelium may be absent on glycerol-asparagine agar, or white aerial mycelium sometimes may be found on this medium, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigments (light brown or olive brown on yeast-malt agar; pale yellow or grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, tryptone-yeast broth, and Gause's medium no. 2. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1606, ATCC 12309, CBS 370.58, CBS 690.72, BCRC 13668, CFBP 4540, CIP 105123, DSM 40449, NBRC 13389, NBRC 3337, JCM 4119, JCM 4746, NRRL B-1698, NRRL-ISP 5449, RIA 1350, VKM Ac-1760.

Sequence accession no. (16S rRNA gene): D63867.

146. **Streptomyces distallicus** (Locci, Baldacci and Petrolini Baldan 1969) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium distallicum* Locci, Baldacci and Petrolini Baldan 1969, 42).

Etymology of specific epithet is unknown.

Spore chains are straight to flexuous and ending in hooks. Reverse colors are darker, after 15 d, and then tend to equal those of *S. kentuckensis.* No great differences in aerial mycelium colors. Aerial mycelium is poorer on Bacto Emerson agar and absent on liquid media. Growth at 37°C is inferior to that at 27°C. Type strain produces distamycins A, B and C, and mycolutein.

For sequence similarity, see type strain of *Streptomyces netropsis.*

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 40846, IMI 72676, JCM 4544, NBRC 15815, NCIB (now NCIMB) 8936, NRRL 2886.

Sequence accession no. (16S rRNA gene): AB184703.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), on Validation List no. 38, *Streptomyces distallicus* is proposed as a *nomen revictum* (basonym: "*Streptomyces distallicus*" Arcamone et al. 1959.

According to Labeda (1996) and Hatano et al. (2003), *Streptomyces distallicus* (Locci et al. 1969) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces netropsis* (Finlay et al. 1951) Witt and Stackebrandt 1991.

According to Lanoot et al. (2004), *Streptomyces distallicus* (Locci et al. 1969) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces colombiensis* Pridham et al. (1958).

147. **Streptomyces djakartensis** Huber, Wallhäusser, Fries, Steigler and Weidenmüller 1962, 1191[AL]

dja.kart.en′sis. N.L. masc. adj. *djakartensis* of or belonging to Djakarta, Indonesia, the source of the soil from which the organism was isolated.

Good growth on Czapek's solution agar. Produces niddamycin (3-desacetyl carbomycin B), an anti-bacterial macrolide.

Type strain shows the highest sequence similarity to: *S. ghanaensis*, AY999851, 99.5%; *S. geysiriensis*, DQ442501, 99.5%; *S. minutiscleroticus*, EF178696, 99.5%; *S. mutabilis*, EF178679, 99.4%; *S. rochei*, AB184237, 99.4%; *S. vinaceusdrappus*, AY999929, 99.4%; *S. tuirus*, AB184690, 99.4%; *S. plicatus*, AB184291, 99.4%; *S. calvus*, AB184329, 99.2%; *S. levis*, AB184670, 99.2%; *S. azureus*, EF178674, 99.2%; *S. anandii*, AB184402, 99.1%; *S. asterosporus*, AB184706, 99.1%; *S. flavoviridis*, AB184842, 99.1%; *S. pseudogriseolus*, DQ442541, 99.1%; *S. gancidicus*, AB184660, 99.1%; *S. pilosus*, AB184161, 99.1%; *S. malachitofuscus*, AB184282, 99%; *S. cellulosae*, DQ442495, 99%; *S. aureorectus*, AB184710, 99%; *S. virens*, DQ442554, 99%; *S. carpinensis*, AB184574, 99%; *S. capillispiralis*, AB184577, 99%; *S. brasiliensis*, AB249981, 99%.

Source: isolated from soil from Djakarta, Indonesia.

DNA G+C content (mol%): not known.

Type strain: AS 4.1674, ATCC 13441, DSM 40743, NBRC 15409, JCM 4957, KCTC 9722, NRRL B-12103.

Sequence accession no. (16S rRNA gene): AB184657.

148. **Streptomyces drozdowiczii** Semêdo, Gomes, Linhares, Duarte, Nascimento, Rosado, Margis-Pinheiro, Margis, Silva, Alviano, Manfio, Soares, Linhares and Coelho 2004, 1327[VP]

droz.do.wic′zi.i. N.L. gen. masc. n. *drozdowiczii* of Drozdowicz, named after Adam Drozdowicz, a soil microbiologist who worked in Brazil.

Spore chains in Section *Rectiflexibiles.* Oval spores, borne in chains on the tip of the aerial mycelium. Spore surface is smooth. Branched, gray colored aerial mycelium is produced on inorganic salts-starch agar. The substrate mycelium has no distinctive pigment, but a diffusible yellow-brown pigment is produced. Melanin is produced on tyrosine agar and peptone-yeast extract-iron agar. Cell-wall hydrolysates contain LL-A_2pm. The predominant amino acids in the cell-wall hydrolysate are alanine (major), glycine, glutamic acid, and leucine. The predominant fatty acids found in whole cell methanolysates are $C_{16:0}$ iso (22%), $C_{15:0}$ iso (19%), $C_{15:0}$ anteiso (18%), $C_{17:0}$ iso (10%), $C_{17:0}$ anteiso (7%), $C_{16:0}$ (6%), and $C_{14:0}$ iso (6%). The species description is based on a single strain and hence serves as the type strain description.

Type strain shows no sequence similarity over 99%.

Source: isolated from the Brazilian Atlantic forest soil

(Mendanha Forest. Rio de Janeiro, RJ, Brazil).

DNA G+C content (mol%): not known.

Type strain: M7a, CBMAI 0498, CIP 107837, JCM 13580, NRRL B-24297.

Sequence accession no. (16S rRNA gene): EF654097.

149. **Streptomyces durhamensis** Gordon and Lapa 1966, 754[AL]

dur.ham.en′sis. N.L. masc. adj. *durhamensis* of or belonging to Durham, named after Durham, North Carolina, USA.

Spore chains in Section *Spirales*. Mature spore chains generally contain 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny, but smooth spores may also be seen.

Color of colony: aerial mass color in the Gray or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs in the Gray color series are 3ge, light grayish yellowish brown; 3fe, light brownish gray; and 2dc, yellowish gray. Nearest tab in the Red color series is 5dc, grayish yellowish pink. Reverse side of colony with no distinctive pigments (pale or grayish yellow to yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, sucrose, and raffinose are all utilized for growth. No growth or only traces of growth with rhamnose.

Type strain shows the highest sequence similarity to: *S. filipinensis*, AB184198, 99.8%; *S. puniciscabiei*, AF361785, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1699, ATCC 23194, CBS 742.72, DSM 40539, HAMBI 1064, NBRC 13441, IMET 43359, JCM 4291, JCM 4747, KCTC 9723, NRRL B-3309, NRRL-ISP 5539, RIA 1402, VKM Ac-763.

Sequence accession no. (16S rRNA gene): AY999785.

150. **Streptomyces durmitorensis** Savic, Bratic and Vasiljevic 2007, 2123[VP]

dur.mi.tor.en′sis. N.L. masc. adj. *durmitorensis* of or pertaining to Durmitor, Serbia and Montenegro, where the type strain was isolated.

Spore chains are *Rectiflexibiles*, with 10 or more rod-shaped smooth-surfaced spores (0.5–0.9 × 1–1.5 µm) per chain. Produces a yellowish gray and greenish gray substrate mycelium and a greenish yellow aerial spore-mass on yeast extract-malt extract and glycerol-asparagine agars. Soluble pigments are not formed on oatmeal, yeast extract-malt extract, or glycerol-asparagine agars, while dark gray pigment is formed on inorganic salts-starch agar. Melanoid pigments are not formed on peptone-yeast extract-iron or tyrosine agars. Nitrate is reduced to nitrite, gelatin is liquefied, starch is not hydrolyzed, esculin, and DNA are not degraded. Cellobiose, D(−)-fructose, D(+)-galactose, D(+)-glucose, D(+)-mannose, α-melibiose, D(+)-raffinose, L(+)-rhamnose, D(−)-sucrose, D(+)-xylose, α-trehalose, glycerol, and D(+)-mannitol are utilized for growth, but α-lactose, β-lactose, D(−)-maltose, L(+)-arabinose, D-sorbitol, and *myo*-inositol are not utilized. Acid is produced from glucose. L-Alanine, L-arginine, L-cysteine, L-glycine, L-histidine, L-methionine, L-proline, and L-valine are utilized as sole nitrogen sources, but L-asparagine, L-lysine, L-phenylalanine, ornithine hydrochloride, and thiamine are not utilized. Positive for nitrate reduction, catalase, extracellular protease, haemolysin (β-hemolysis), and urease; lecithinase-negative. H_2S and indole are not produced. Temperature range for growth is 10–37°C, with an optimum between 28 and 32°C. The cell wall contains LL-A_2pm. Grows in the presence of NaCl (9%, w/v) and thallous acetate (0.001%, w/v), but not in sodium-azide (0.01%, w/v), phenol (0.1%, w/v), or potassium tellurite (0.001%, w/v). Susceptible to: apramycin (10 µg/ml), kanamycin (5 µg/ml), gentamicin (5 µg/ml), tetracycline (10 µg/ml), thiostrepton (10 µg/ml), chloramphenicol (35 µg/ml), and spectinomycin(90 µg/ml). Resistant to: ampicillin (100 µg/ml), erythromycin (100 µg/ml), and FK506 (100 µg/ml). Shows antimicrobial activity against *Micrococcus luteus* NCIMB 196 and *Saccharomyces cerevisiae* FAV20, but not against *Bacillus subtilis* NCIMB 3610, *Candida albicans* CBS 562, *Escherichia coli* ATCC 25922, *Pseudomonas aeruginosa* ATCC 27853, *Saccharomyces cerevisiae* FAS20, or *Staphylococcus aureus* ATCC 25923.

Type strain shows the highest sequence similarity to: *S. aureus*, AB249976, 99.6%; *S. kanamyceticus*, DQ442511, 99.2%. Type strain shows DNA–DNA similarity to: *S. aureus* DSM 41785[T], 15.5%; *S. kanamyceticus* DSM 40500[T], 13.3%.

Source: not known.

DNA G+C content (mol%): 72.0.

Type strain: MS405, CIP 108995, DSM 41863.

Sequence accession no. (16S rRNA gene): DQ067287.

151. **Streptomyces echinatus** Corbaz, Ettlinger, Gäumann, Keller-Schierlein, Kradolfer, Neipp, Prelog, Reusser and Zähner 1957a, 203[AL]

e.chi.na′tus. L. masc. adj. *echinatus* set with prickles, prickly.

Spore chain morphology in Section *Retinaculiaperti* or *Spirales*. Tight spirals sometimes occur at tips of sporophores. Mature spore chains generally have 10–50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow modified by green on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth (growth on L-arabinose and D-xylose is less than on other sugars). No growth or only traces of growth on sucrose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1642, ATCC 19748, ATCC 21133, CBS 409.59, CBS 487.68, BCRC 13656, CECT 3313, DSM 40013, HUT 6090, IFM 1076, NBRC 12763, IMET 40461, JCM 4144, JCM 4574, KCTC 9724, LMG 5972, NCIMB 9598, NCIMB 9799, NRRL 2587, NRRL-ISP 5013, RIA 1029, UNIQEM 135, VKM Ac-762.

152. **Streptomyces echinoruber** Palleroni, Reichelt, Müller, Epps, Tabenkin, Bull, Schüep and Berger 1981, 382[VP] (Effective publication: Palleroni, Reichelt, Müller, Epps, Tabenkin, Bull, Schüep and Berger 1978, 1224.)

e.chi.no.ru′ber. L. n. *echinus* a hedgehog, urchin; L. adj. *ruber* red; N.L. masc. adj. *echinoruber* spiny red.

Strain shows gray spore mass color, spiral spore chains, and spiny spore surface. Colonies are raised and coarse, with well-defined edges. The most striking character of strain X-14077[T] is the production of the deep cherry-red pigment which freely diffuses into the medium. This pigment is produced in most media tested and it becomes evident after 1 or 2 d of incubation. For a more detailed description of morphological properties, see Palleroni et al. (1978).

Sequence accession no. (16S rRNA gene): no sequence available.

153. **Streptomyces ederensis** Wallhäusser, Nesemann, Präve and Steigler 1966, 734[AL]

e.der.en′sis. N.L. masc. adj. *ederensis* of or pertaining to Eder, named for the Eder valley in Germany.

Produces the moenomycin complex of anti-bacterial antibiotics comprised of moenomycins A, B_1, B_2, and C.

Type strain shows the highest sequence similarity to: *S. umbrinus*, AB184305, 100%; *S. phaeochromogenes*, AB184738, 99.6%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1665, ATCC 15304, CBS 545.70, BCRC 11896, CECT 3212, DSM 40741, NBRC 15410, JCM 4958, KCTC 9726, NRRL B-8146, VKM Ac-845.

Sequence accession no. (16S rRNA gene): AB184658.

154. **Streptomyces ehimensis** corrig. (Shibata, Honso, Tokui and Nakazawa 1954) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces ehimensis*" Shibata, Honso, Tokui and Nakazawa 1954, 168; "*Verticillomyces ehimensis*" Shinobu 1965, 109; *Streptoverticillium ehimense* Locci, Baldacci and Petrolini Baldan 1969, 40).

Etymology of specific epithet is unknown.

Spore chain morphology in Section *Verticillati*. Mature aerial mycelium is usually umbellate-monoverticillate (biverticillate), but sporulating aerial mycelium is very sparse or absent on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Biverticillate spore chains can be seen on Pridham and Gottlieb carbon utilization medium plus D-xylose or L-arabinose and sometimes can be found on oatmeal agar after 21 d. Spore chains are short, usually with 3–10 spores per chain. Spore surface is smooth.

Color of colony: aerial mass color for mature sporulating aerial mycelium cannot be determined accurately because of poor sporulation on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. When sporulating aerial mycelium occurs on oatmeal agar, it is in the Gray color series. The spore surface of poorly sporulating growth is generally in the Yellow or Red color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar or sparse aerial mycelium may be white. Reverse side of colony is brown to dark brown on yeast-malt agar, but grayish yellow, orange yellow, or yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar and tryptone-yeast broth, but only weakly or not at all on tyrosine agar. Yellow or grayish yellowish brown pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive.

D-Glucose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. Traces of growth occur on the carbon-free control and on other ISP carbon sources.

Type strain shows the highest sequence similarity to: *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99.8%; *S. abikoensis*, AB184537, 99.6%; *S. sapporonensis*, AB184508, 99.4%; *S. lilacinus*, AB184819, 99.3%; *S. luteireticuli*, AB249969, 99.2%; *S. varsoviensis*, DQ026653, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1668, ATCC 23903, CBS 799.68, BCRC 13319, DSM 40253, HAMBI 1042, NBRC 12858, NBRC 3398, JCM 4162, JCM 4635, KCTC 9727, NRRL B-1967, NRRL-ISP 5253, RIA 1179, VKM Ac-945.

Sequence accession no. (16S rRNA gene): AY999834.

Further comments: the original spelling, *Streptomyces ehimensis* (*sic*), has been corrected in accordance with Rule 61 of the *Bacteriological Code* (1990 Revision).

In violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces ehimensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces ehimensis*" Shibata et al. 1954.

According to Hatano et al. (2003), *Streptomyces ehimensis* corrig. (Shibata et al. 1954) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces abikoensis* (Umezawa et al. 1951) Witt and Stackebrandt 1991.

155. **Streptomyces emeiensis** Sun, Huang, Zhang and Liu 2007, 1638[VP]

e.me.i.en′sis. N.L. masc. adj. *emeiensis* of or pertaining to Emei, a famous mountain in Sichuan Province, southern China, where the sample yielding the type strain was collected.

Aerobic, mesophilic, Gram-stain-positive actinomycete that develops well-branched substrate and aerial mycelium. *Rectiflexibiles* and hooked spore chains of elliptical, spiny-surfaced spores are frequently arranged in a verticillate structure. Diffusible pigments are not formed, nor are melanin pigments produced on peptone-yeast extract-iron or tyrosine agars. Nitrate is reduced. Amylase and gelatinase are not produced. Growth occurs between 15 and 40°C and at pH values from 5.5 to 9.5, but not at pH 4.5 or 10.5. Growth occurs in the presence of 0.1% (w/v) phenol, 5% (w/v) NaCl, and 0.01 (w/v) NaN_3, but not in the presence of 7% (w/v) NaCl. Shows weak antimicrobial activity against strains of *Bacillus subtilis* and *Mycobacterium smegmatis*, but not against strains of *Staphylococcus epidermis*, *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, or *Candida albicans*. Sensitive to filter-paper discs soaked in the following (µg/ml): novobiocin (5), streptomycin (10), oxacillin (1), chloramphenicol (30), ciprofloxacin (5), and erythromycin (15). The cell-wall is of type I. Type II phospholipids and menaquinones MK-9(H_6, H_8, H_4) are detected. The fatty acid profile is composed of $C_{15:0}$ anteiso (14.6%), $C_{16:0}$ iso (13.3%), $C_{17:0}$ anteiso (12.6%), $C_{16:0}$ (9.4%), $C_{16:1}\omega7c$ (8.2%), $C_{17:1}$ anteiso$\omega9c$ (7.0%), $C_{18:0}$ (3.7%), $C_{17:1}\omega8c$ (3.6%), iso H-$C_{16:1}$ (3.6%), $C_{15:0}$ (3.1%), $C_{15:0}$ iso (3.0%), $C_{17:1}$ iso$\omega9c$ (3.0%), $C_{15:0}$ iso (3.0%), $C_{14:0}$ (2.8%), $C_{18:1}\omega9c$ (2.4%), $C_{18:1}\omega7c$ (1.6%), $C_{17:0}$ iso (1.3%), $C_{17:0}$ (1.1%), $C_{14:0}$ iso (1.1%), and iso I-$C_{15:1}$ (1.1%).

Type strain shows the highest sequence similarity to: *S. prasinopilosus*, EF626597, 99.4%. Type strain shows DNA–DNA similarity to: *S. prasinopilosus* DSM 40098^T, 62.7%; *S. prasinus* JCM 4603^T, 55.5%; *S. hirsutus* DSM 40095^T, 46.4%; *S. bambergiensis* DSM 40590^T, 31.7%; *S. cyanoalbus* DSM 40198^T, 26.1%.

Source: the type strain was isolated from a soil sample collected from Emei Mountain, Sichuan Province, China.

DNA G+C content (mol%): 70.8.

Type strain: 4776, CGMCC 4.3504, DSM 41884.

Sequence accession no. (16S rRNA gene): DQ462649.

156. **Streptomyces endus** Anderson and Gottlieb 1952, 302[AL]

en′dus. L. praep. *endo* in; N.L. masc. adj. *endus* referring to the site (inside the hyphae) of formation of the antibiotic endomycin.

Spore chains in Section *Spirales* with tightly closed spirals. Individual spores are not easily detached from the spiral chain and compact coils may become hydroscopic (coalesce in black moist droplets). Spore surface is warty.

Color of colony: aerial mass color in the Gray color series after 21 d on yeast-malt agar, oatmeal agar, and salts-starch agar. Aerial mycelium on glycerol-asparagine agar and young aerial mycelium on other media may be white. Older colonies sometimes become moist and black. Reverse side of colony with no distinctive pigments (grayed yellow to yellowish brown or gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. In older cultures, the substrate mycelium sometimes becomes moist and black. Substrate color is not affected by pH change.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigments are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: 9-20, ATCC 23904, CBS 800.68, DSM 40187, NBRC 12859, JCM 4213, JCM 4636, NRRL 2339, NRRL-ISP 5187, RIA 1141.

Sequence accession no. (16S rRNA gene): AY999911.

Type strain shows the highest sequence similarity to: *S. sporocinereus*, AB249933, 100%; *S. hygroscopius* subsp. *hygroscopius*, AB184428, 100%; *S. demainii*, DQ334782, 99.9%; *S. yogyakartensis*, AB249942, 99.5%; *S. violaceusniger*, AJ391823, 99.5%; *S. albiflaviniger*, AJ391812, 99.3%.

157. **Streptomyces enissocaesilis** (*ex* Krasil'nikov 1970b) Sveshnikova 1986, 574[VP] (Effective publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces enissocaesilis*" Krasil'nikov 1970b).

Etymology of specific epithet is unknown.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: aerial mycelium is light pink-yellowish-grayish; substrate mycelium is brown; diffusible pigment is brown with grayish violet shadows. On starch-ammonia agar: aerial mycelium is absent or poorly developed, whitish; substrate mycelium is colorless to pale yellowish, growth is poor; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is white to brownish pink; substrate mycelium and diffusible pigment are brown to dark brown. On glycerol-asparagine agar: aerial mycelium is absent or poorly developed, whitish; substrate mycelium is black-grayish brown; no diffusible pigment. On oatmeal agar: aerial mycelium is poorly developed; substrate mycelium is brown; diffusible pigment is brownish, weak. On organic agar 2: aerial mycelium is light pink-yellowish-grayish; substrate mycelium and diffusible pigment are brown. Melanoid pigment: not extant or poorly developed. Grows on glucose, arabinose, xylose, and mannitol; no growth seen on sucrose, rhamnose, or raffinose.

Type strain shows the highest sequence similarity to: *S. flavidovirens*, AB184270, 99.2%; *S. chryseus*, AY999787, 99.1%; *S. helvaticus*, AB184367, 99.1%; *S. albidochromogenes*, AB249953, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1586, ATCC 43682, DSM 41454, INMI 40-31, JCM 9088, NBRC 100763, NRRL B-16365, VKM Ac-130.

Sequence accession no. (16S rRNA gene): AB249930.

158. **Streptomyces erumpens** Calot and Cercós 1963, 159[AL]

e.rum′pens. L. masc. part. adj. *erumpens* bursting forth.

Poor growth on Czapek's solution agar. Exhibits antibacterial activity; inhibited by streptomycin; produces the tetraenic anti-fungal antibiotic 17732 (tetrins A and B and another polyene).

Type strain shows the highest sequence similarity to: *S. rimosus* subsp. *rimosus*, AB045883, 99.7%; *S. monomycini*, DQ445790, 99.4%; *S. chrestomyceticus*, AJ621609, 99.3%; *S. rimosus* subsp. *paromomycinus*, AJ621610, 99.3%; *S. ochraceiscleroticus*, AB184094, 99.3%; *S. sioyaensis*, DQ026654, 99.2%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.2%; *S. purpurogeneiscleroticus*, AJ621604, 99.1%; *S. albofaciens*, AB045880, 99.1%; *S. violens*, AJ621605, 99.1%; *S. sclerotialus*, AJ621608, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1626, ATCC 23266, CBS 252.65, DSM 40941, NBRC 15403, JCM 5060, KCTC 9729, NRRL B-3163.

Sequence accession no. (16S rRNA gene): AJ621603.

Further comments: according to Guo et al. (2008), *Streptomyces erumpens* Calot and Cercós 1963 is a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948.

159. **Streptomyces erythraeus** (Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 938[AL] ["*Actinomyces erythreus*" (*sic*) Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923, 370; "*Streptomyces erythreus*" (*sic*) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 938]

e.ry.thra′e.us. L. masc. adj. *erythraeus* reddish, referring to colony color.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Spore chains are usually short so that imperfect spirals, hooks, or loops of only one turn, and short, straight to flexuous chains are common. Hooks and loops are usually of small diameter and are not representative of true *Retinaculiaperti* morphology. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but aerial mycelium may be poorly developed on glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red color series (4ec, 5cb, 5db, grayish yellowish pink; or 3ca, pale orange yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. White aerial mycelium may also be seen. Reverse side of colony is brown to grayish reddish brown on yeast-malt agar; orange-yellow to light yellowish brown or grayish yellow on oatmeal agar and salts-starch agar; yellowish brown to strong brown on glycerol-asparagine agar. Reverse mycelium pigment is usually not a pH indicator, but, when pink pigment is present, it may change to pale yellow with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Pink or yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but pigment is not always present on these media. Pink pigment, when present, becomes colorless with the addition of either 0.05 M HCl or NaOH.

D-Glucose, D-fructose, sucrose, raffinose, and D-mannitol are utilized for growth. Reports vary on utilization of L-arabinose, D-xylose, iso-inositol, and rhamnose. Significant growth is often observed on control plates of carbon-utilization medium without added carbon source.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 11635, CBS 727.72, DSM 40517, HUT 6087, IAM 0045, NBRC 13426, JCM 4748, IMRU 3737, NCIB (now NCIMB) 8594, NRRL 2338, NRRL-ISP 5517, RIA 1387, VKM Ac-1189.

Sequence accession no. (16S rRNA gene): no sequence available.

Further comments: the type strain of *Streptomyces erythraeus* (Waksman 1923) Waksman and Henrici 1948 is not a representative of the genus *Streptomyces* Waksman and Henrici 1943 and a new species, *Saccharopolyspora erythraea* Labeda 1987, is created for this strain and other strains having type IV cell walls. Labeda (1987) also proposed an emendation of *Streptomyces erythraeus* [*Streptomyces erythraeus* (Waksman 1923) Waksman and Henrici 1948 emend. Labeda 1987] with a neotype strain NRRL B-5616^T (NRRL-ISP 5059^T, Sanchez-Marroquin A-24^T). According to Rules 18c and 18g of the *Bacteriological Code* (1990 Revision), only the Judicial Commission may decide to take action leading to replacement of the type strain and, according to Rule 37a(2) of the *Bacteriological Code* (1990 Revision), retention of a name in a sense which excludes the type can only be effected by conservation and only by the Judicial Commission. Therefore, *Streptomyces erythraeus* (Waksman 1923) Waksman and Henrici 1948 emend. Labeda 1987 is illegitimate and may not be used [Rule 51a of the *Bacteriological Code* (1990 Revision)] and a new species *Streptomyces labedae* Lacey 1987 is provided for this taxon (Lacey, 1987).

Rule 17 of the *Bacteriological Code* (1990 Revision) states that the type determines the application of a taxon if the taxon is subsequently divided or united with another taxon, and Rule 40b of the *Bacteriological Code* (1990 Revision) that the specific epithet must be retained for the species which includes the type strain. Since *Saccharopolyspora erythraea* (Waksman 1923) Labeda 1987 contains the type strain of *Streptomyces erythraeus* (Waksman 1923) Waksman and Henrici 1948, the new taxon must be regarded as a new combination.

160. **Streptomyces erythrogriseus** Falcão de Morais and Dália Maia 1959, 64[AL]

e.ry.thro.gri′se.us. Gr. adj. *euruthros* red; N.L. adj. *griseus* gray; N.L. masc. adj. *erythrogriseus* red, gray (referring to change in color of aerial mycelium from gray to red).

Spore chains in Section *Spirales*, but short spore chains may form imperfect or incomplete spirals or crooked hooks or loops. Spirals are most numerous on salts-starch agar after 14 d and are rare on yeast-malt agar

and glycerol-asparagine agar. Mature spore chains are generally short, with 3 to 10 or more spores per chain, but long chains with more than 50 spores are also reported. Spore surface is spiny with short spines. Smooth spores are also found.

Color of colony: aerial mass color usually in the Gray color series on yeast-malt agar and salts-starch agar; Gray, Red, or White color series on glycerol-asparagine agar. Aerial mycelium suitable for color determination is usually not formed on oatmeal agar, but when present it is in the Gray color series. Nearest matching color tabs in the Gray color series are d, light gray, and 5fe, light grayish reddish brown. Nearest matching tabs in the Red color series are 5ge, light grayish reddish brown and 5dc, light yellowish pink. Reverse side of colony is strong brown on yeast-malt agar; orange yellow to yellowish brown on oatmeal agar and salts-starch agar; reddish orange to reddish brown on glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator, changing from yellow to orange with the addition of 0.05 M NaOH and from yellow brown to yellow with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow to orange pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When this pigment is present, it is pH-sensitive, showing the same changes observed in the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. griseoincarnatus*, AJ781328, 100%; *S. labedae*, AB184704, 100%; *S. variabilis*, DQ442551, 100%; *S. griseorubens*, AB184139, 99.9%; *S. griseoflavus*, AJ781322, 99.6%; *S. matensis*, AB184221, 99.6%; *S. althioticus*, AY999808, 99.2%; *S. paradoxus*, AB184628, 99.2%; *S. heliomycini*, AB184712, 99.1%; *S. flaveolus*, AB184764, 99.1%; *S. collinus*, AB184123, 99.1%; *S. viridochromogenes*, DQ442555, 99.1%; *S. bellus*, AB184849, 99%; *S. albogriseolus*, AJ494865, 99%; *S. viridodiastaticus*, AY999852, 99%; *S. violaceochromogenes*, AY999867, 99%; *S. malachitofuscus*, AB184282, 99%; *S. violaceorubidus*, AJ781374, 99%; *S. coerulescens*, AY999720, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27427, CBS 485.74, BCRC 13770, DSM 40116, NBRC 14601, JCM 9650, NRRL B-3808, NRRL-ISP 5116.

Sequence accession no. (16S rRNA gene): AJ781328.

161. **Streptomyces eurocidicus** (Okami, Utahara, Nakamura and Umezawa 1954) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces eurocidicus*" Okami, Utahara, Nakamura and Umezawa 1954, 102; "*Verticillomyces eurocidicus*" Shinobu 1965, 111; *Streptoverticillium eurocidicum* Locci, Baldacci and Petrolini Baldan 1969, 36)

eu.ro.ci′di.cus. N.L. n. *eurocidinum* eurodicin; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *eurocidicus* belonging to eurodicin.

Spore chains in Section Umbellate Monoverticillate (=*Streptomyces* Section Verticillati biverticillate). Mature spore chains contain 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (1ba or 2ba, pale yellow; 1½db, pale greenish yellow; 1db, pale yellow green; 1½fb, light yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (olive brown to reddish brown on yeast-malt agar; pale grayish yellow to yellowish brown or olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, iso-inositol, and D-fructose are utilized for growth. No growth or only traces of growth with L-arabinose, D-xylose, D-mannitol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. albireticuli*, AB184881, 99.8%; *S. werraensis*, DQ442558, 99.3%; *S. biverticillatus*, AJ781381, 99.3%; *S. blastmyceticus*, AY999802, 99.2%; *S. stramineus*, AB184720, 99.2%; *S. netropsis*, AB184848, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1086, ATCC 27428, CBS 792.72, BCRC 12424, CECT 3259, DSM 40604, NBRC 13491, IMET 43412, JCM 4029, JCM 4749, NRRL B-1676, NRRL-ISP 5604, RIA 1452, RIA 733, VKM Ac-903.

Sequence accession no. (16S rRNA gene): AY999790.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces eurocidicus* is proposed as a *nomen revictum* (basonym: "*Streptomyces eurocidicus*" Okami et al. 1954.

According to Hatano et al. (2003), *Streptomyces eurocidicus* (Okami et al. 1954) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces albireticuli* (Nakazawa 1955) Witt and Stackebrandt 1991.

162. **Streptomyces europaeiscabiei** Bouchek-Mechiche, Gardan, Normand and Jouan 2000, 98[VP]

eu.ro.pa.ei.sca′bi.ei. L. adj. *europaeus* european; L. n. *scabies* scab, mange; N.L. gen. n. *europaeiscabiei* of European scab, referring to the European origin of the strains.

Spores are gray and are borne in mature spiral chains. Melanin is produced on tyrosine agar. L-Arabinose, D-fructose, D-glucose, D-mannitol, inositol, raffinose, rhamnose, sucrose, and D-xylose are utilized for growth. Degradation of xanthine differs between the strains studied. All strains are susceptible to 20 μg/ml streptomycin and 0.5 μg/ml crystal violet. They are not susceptible to 25 μg/ml oleandomycin or 10 IU/ml penicillin G. They utilize *trans*-aconitate, D(+)trehalose, ONPG, melibiose, and 5-keto-D-gluconate; most (about 78%) of the strains assimilate gentisate. They do not use betaine, mucate, D-saccharate, DL-lactate, or turanose.

Type strain shows the highest sequence similarity to: *S. scabies*, D63862, 99.8%. Type strain shows DNA–DNA similarity to: *S. stelliscabiei* DSM 41803^T, 42%; *S. reticuliscabiei* DSM 41804^T, 20%.

Source: these strains were isolated from common scab lesions, mostly on potato, but also on carrot and beet, and have been confirmed to be pathogenic on potato cvs Bintje and Urgenta, on carrot cv. Premia and on radish cv. Polka.

DNA G+C content (mol%): 71.3.

Type strain: CFBP 4497, CIP 107062, DSM 41802, ICMP 13714, KACC 20186, NCPPB 4039.

Sequence accession no. (16S rRNA gene): AY207598.

163. **Streptomyces eurythermus** Corbaz, Ettlinger, Gäumann, Keller-Schierlein, Kradolfer, Kyburz, Neipp, Prelog, Reusser and Zähner 1955, 1202^{AL}

eu.ry.ther′mus. Gr. adj. *eurus* wide; Gr. adj. *thermos* hot; N.L. masc. adj. *eurythermus* wide, hot.

Spore chains in Section *Retinaculiaperti* (including many straight and flexuous spore chains and occasional spirals). Mature spore chains generally have 10–50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator. One observer reports slight change from yellowish brown to reddish brown with addition of 0.05 M NaOH.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Variable reports on growth with iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. nogalater*, AB045886, 99.2%; *S. fragilis*, AY999917, 99%; *S. tendae*, D63873, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1697, ATCC 14975, ATCC 19749, CBS 488.68, BCRC 13650, DSM 40014, NBRC 12764, IMET 43078, JCM 4206, JCM 4575, KCTC 9731, NRRL 2539, NRRL-ISP 5014, RIA 1030, VKM Ac-1729.

Sequence accession no. (16S rRNA gene): D63870.

164. **Streptomyces exfoliatus** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 951^{AL} ("*Actinomyces exfoliatus*" Waksman and Curtis 1916, 116)

ex.fo.li.a′tus. L. masc. part. adj. *exfoliatus* stripped of leaves.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. Typical morphology on oatmeal agar. Some sporulation aerial mycelium with typical morphology on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. One observer reported fragmentation and spore formation in substrate-mycelium on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 14 d; another observer reported coremia formation on glycerol-asparagine agar in 14 d.

Color of colony: aerial mass color in the Red color series on oatmeal agar; sporulation aerial mycelium is also in the Red series on yeast-malt agar and salts-starch agar when formed on these media. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-fructose, rhamnose, and raffinose are utilized for growth. No growth on iso-inositol or D-mannitol.

Type strain shows the highest sequence similarity to: *S. zaomyceticus*, EF178685, 99.9%; *S. venezuelae*, AB045890, 99.9%; *S. lateritius*, AJ781326, 99.7%; *S. wedmorensis*, DQ442557, 99.7%; *S. litmocidini*, AB184149, 99.6%; *S. omiyaensis*, EF178697, 99.6%; *S. yereyanensis*, EF178684, 99.4%; *S. narbonensis*, DQ445794, 99.3%.

Source: not known.

Type strain: AS 4.1407, ATCC 12627, ATCC 19750, CBS 489.68, BCRC 11469, CCUG 11113, DSM 40060, NBRC 13191, JCM 4366, LMG 19307, NCIMB 12599, NRRL B-1237, NRRL B-2924, NRRL-ISP 5060, PCM 2367, RIA 1031, UNIQEM 137, VKM Ac-767.

Sequence accession no. (16S rRNA gene): AB184324.

165. **Streptomyces felleus** Lindenbein 1952, 374^{AL}

fel′le.us. L. masc. adj. *felleus* of gall, like gall (pertaining to the bitter taste of proactinomycin A).

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment in medium or faint yellow to yellowish green color in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. canescens*, AB184117, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. hydrogenans*, AB184868, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. sampsonii*, D63871, 99.8%; *S. koyangensis*, AY079156, 99.7%.

Source: not known.

Type strain: AS 4.1677, ATCC 19752, CBS 491.68, BCRC 11471, DSM 40130, NBRC 12766, JCM 4368, NCIMB 12974, NRRL-ISP 5130, RIA 1033, UNIQEM 139, VKM Ac-722.

Sequence accession no. (16S rRNA gene): AB184129.

166. **Streptomyces ferralitis** Saintpierre-Bonaccio, Amir, Pineau, Lemriss and Goodfellow 2004, 2064[VP]

fer.ra'li.tis. N.L. gen. n. *ferralitis* of ferralite, denoting the type of soil from which the type strain was isolated.

Forms an extensively branched substrate mycelium and aerial hyphae that differentiate into looped or spiral chains of spores. The spore chains consist of up to 15 barrel-shaped spores with smooth surface. A brown substrate mycelium and a white aerial spore mass are formed on modified Bennett's agar (Jones, 1949). Melanin pigments are not produced on peptone-yeast extract-iron agar. The culture grows well at 20 and 45°C, but does not grow at 10°C. Metabolizes casein, hypoxanthine, L-tyrosine, urea, and xanthine, but not adenine, elastin, gelatin, guanine, starch, Tween 80, or xanthine. D(+)-Galactose, D(+)-glucose, D(+)-mannitol, D(+)-mannose, and D(+)-trehalose are used as sole carbon sources for energy and growth, but adonitol, D-arabinose, D(+)-cellobiose, D(+)-melibiose, and sodium citrate are not. Resistant to penicillin (25 µg/ml), but does not grow in the presence of erythromycin (4 µg/ml), gentamicin sulfate (10 µg/ml), rifampin (6 µg/ml), streptomycin sulfate (5 µg/ml), tetracycline hydrochloride (30 µg/ml), vancomycin hydrochloride (10 µg/ml), crystal violet (0.0002%, w/v), phenol (0.01%, w/v), potassium tellurite (0.005%, w/v), or sodium chloride (5%, w/v). It shows activity against clinical isolates of *Candida albicans*, *Staphylococcus aureus*, *Staphylococcus epidermidis* and a *Corynebacterium* strain, but not against *Fusarium oxysporum*, *Bacillus*, *Erwinia*, *Escherichia coli*, *Klebsiella pneumoniae*, or *Pseudomonas aeruginosa* strains. The species description is based upon a single strain and hence serves as the description of the type strain.

Type strain shows no sequence similarity over 99%.

Source: the type strain was isolated from a ferralitic, oxidic ultramafic soil collected at the southern end of the main island of New Caledonia.

DNA G+C content (mol%): not known.

Type strain: SFOp68, DSM 41836, NCIMB 13954.

Sequence accession no. (16S rRNA gene): AY262826.

167. **Streptomyces fervens** (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces fervens*" DeBoer Dietz, Evans and Michaels 1959–1960), 220; (*Streptoverticillium fervens* Locci, Baldacci and Petrolini Baldan 1969, 23)

fer'vens. L. part. adj. *fervens* boiling hot, referring to its high growth temperature.

Spore chain morphology: Section not determined. Sporulating aerial mycelium is not produced on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Note that the original descriptions of DeBoer et al. and Locci et al. (op. cit) call attention to the limited sporulation; they report verticillate morphology. Spore surface is smooth.

Color of colony: the thin aerial mycelium, which generally lacks sporophores and spore chains, is in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Two observers report that an appropriate color tab cannot be found in the red color wheel of Tresner and Backus; one observer identifies nonsporulating aerial mycelium color as 7 ca, light yellowish pink. Reverse side of colony with distinctive red color reported as dark red or eosin red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is pH-sensitive, changing from deep red to reddish brown with the addition of 0.05 M NaOH and from red to violet red with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment other than melanoids is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and iso-inositol are utilized for growth. A trace of growth is seen on L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, sucrose and raffinose; utilization of these carbon sources is doubtful.

For sequence similarity, see type strain of *Streptomyces hiroshimensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27429, JCM 4310, JCM 4750, NBRC 13343, NRRL 2755.

Sequence accession no. (16S rRNA gene): AB184871.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces fervens* is proposed as a *nomen revictum* (basonym: "*Streptomyces fervens*" DeBoer et al. 1959–1960).

Witt and Stackebrandt proposed to transfer *Streptoverticillium fervens* (DeBoer et al. 1959–1960) Locci et al. 1969 to the genus. However, Validation List no. 38 does not include formal propositions about *Streptoverticillium fervens* subsp. *fervens* Baldacci and Locci 1974 and *Streptoverticillium fervens* subsp. *melrosporus* Mason et al. 1965.

Labeda (1996) proposes *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991, *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991, and *Streptomyces roseoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 as later synonyms of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991. This proposal is in violation of Rule 24b(1) of the *Bacteriological Code* (1990 Revision) because the senior epithet is *roseoverticillatus*. *Streptomyces baldaccii*, *Streptomyces biverticillatus*, and *Streptomyces fervens* are therefore to be regarded as later synonyms of *Streptomyces roseoverticillatus*.

According to Hatano et al. (2003), *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

168. **Streptomyces filamentosus** Okami and Umezawa *in* Okami, Okuda, Takeuchi, Nitta and Umezawa 1953, 153[AL] emend. Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2004, 88.)

fi.la.men.to′sus. L. n. *filamentum* assembly of threads; L. masc. suff. *-osus* suffix used with the sense of full of, prone to; N.L. masc. adj. *filamentosus* full of threads or filaments.

Spore chains in Section *Rectiflexibiles.* Mature spore chains generally have 10–50 spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, and rhamnose are utilized for growth. No growth or only trace of growth on iso-inositol, D-mannitol, and raffinose. Variable reports on utilization of D-fructose.

Type strain shows the highest sequence similarity to: *S. roseolus*, AB184168, 99.4%; *S. roseoviridis*, AB184239, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1656, ATCC 19753, CBS 492.68, BCRC 13644, DSM 40022, HAMBI 1010, IFM 1180, NBRC 12767, IMET 43562, JCM 4122, JCM 4576, NCIMB 13018, NRRL B-2114, NRRL-ISP 5022, RIA 1034, UNIQEM 140, VKM Ac-1266.

Sequence accession no. (16S rRNA gene): AB184130.

Further comments: according to Lanoot et al. (2004), *Streptomyces filamentosus* Okami and Umezawa 1953 is an earlier heterotypic synonym of *Streptomyces roseosporus* Falcão de Morais and Dália Maia 1961.

169. **Streptomyces filipinensis** Ammann, Gottlieb, Brock, Carter and Whitfield 1955, 559[AL]

fi.li.pi.nen′sis. N.L. masc. adj. *filipinensis* of or belonging to the Philippines, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales.* Tight spirals or open coils, usually of several turns, occur at the end of moderately long spore chains or 10 to 50 or more spores per chain on yeast-malt agar, oatmeal agar, and salts-starch agar. Spirals may be replaced by *Retinaculiaperti* morphology on glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar, tyrosine agar, and peptone-yeast broth. Pigments other than melanoids are not found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Carbon utilization: D-glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose and raffinose are utilized for growth. No growth or only trace of growth on rhamnose.

Type strain shows the highest sequence similarity to: *S. durhamensis*, AY999785, 99.8%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1452, ATCC 23905, CBS 309.56, CBS 801.68, BCRC 11472, DSM 40112, NBRC 12860, JCM 4369, LMG 19333, NRRL 2437, NRRL-ISP 5112, RIA 1124, VKM Ac-966.

Sequence accession no. (16S rRNA gene): AB184198.

170. **Streptomyces fimbriatus** (Millard and Burr 1926) Waksman *in* Waksman and Lechevalier 1953, 104[AL] ("*Actinomyces fimbriatus*" Millard and Burr 1926, 639)

fim.bri.a′tus. L. masc. adj. *fimbriatus* fibrous, fringed.

Excellent growth on Czapek's solution agar. Produces septacidin, an anti-tumor and anti-fungal purine antibiotic; not inhibited by streptomycin.

Type strain shows no sequence similarity over 99%.

Source: Millard and Burr's original single isolate (no longer extant) was obtained from a case of common potato scab.

DNA G+C content (mol%): not known.

Type strain: AS 4.1598, ATCC 15051, CBS 453.65, DSM 40942, NBRC 15411, JCM 5080, NCIMB 13039, NRRL B-3175, VKM Ac-761.

Sequence accession no. (16S rRNA gene): AY999844.

171. **Streptomyces fimicarius** (Duché 1934) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 940[AL] ("*Actinomyces fimicarius*" Duché 1934, 346)

fi.mi.ca′ri.us. L. n. *fimus* dung, manure; L. adj. *carus* dear, loving; N.L. masc. adj. *fimicarius* dung-loving.

Spore chains Section *Rectiflexibiles.* Mature spore chains are generally long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Fragmentation of the substrate mycelium may be seen on glycerol-asparagine agar in 16 d.

Color of colony: aerial mass color in the Yellow or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow to yellowish brown) on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; yellow is modified by red (to orange or reddish brown) on yeast-malt agar. This pigment changes from reddish brown to pale brown with addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast

broth (but according to one observer, some brown pigment is formed in the medium in Gause's medium no. 2). Red (pink to light reddish brown) pigment is found in the medium in yeast-malt agar and oatmeal agar; it may or may not be seen in salts-starch agar and glycerol-asparagine agar. This pigment is pH-sensitive, changing from pink or reddish brown to yellow when tested with 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Only traces of growth is seen with iso-inositol, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. anulatus*, DQ026637, 100%; *S. badius*, AY999783, 100%; *S. sindenensis*, AB184759, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. griseinus*, AB184205, 100%; *S. acrimycini*, AY999889, 100%; *S. flavofuscus*, AB249935, 100%; *S. mediolani*, AB184674, 100%; *S. praecox*, AB184293, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. griseoplanus*, AY999894, 100%; *S. microflavus*, DQ445795, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. fulvorobeus*, AB184711, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. baarnensis*, EF178688, 99.9%; *S. globisporus* subsp. *globisporus*, EF178686, 99.9%; *S. albovinaceus*, AB249958, 99.9%; *S. alboviridis*, AB184256, 99.9%; *S. californicus*, AB184755, 99.8%; *S. parvus*, DQ442537, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. halstedii*, EF178695, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavogriseus*, AJ494864, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. floridae*, AB184656, 99.7%; *S. flavovirens*, DQ026635, 99.7%;%; *S. nitrosporeus*, EF178680, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. atroolivaceus*, AJ781320, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. clavifer*, DQ026670, 99.5%; *S. yanii*, AB006159, 99.4%; *S. gelaticus*, DQ026636, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. mutomycini*, AB249951, 99.3%; *S. celluloflavus*, AB184476, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. spiroverticillatus*, AB184814, 99.2%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. candidus*, DQ026663, 99.1%; *S. mauvecolor*, AB184532, 99%; *S. cremeus*, AB184124, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1629, ATCC 25449, CBS 420.34, CBS 682.69, BCRC 12245, DSM 40322, NBRC 13037, JCM 4472, NRRL-ISP 5322, RIA 1229, VKM Ac-1724.

Sequence accession no. (16S rRNA gene): AY999784.

172. **Streptomyces finlayi** (Szabó, Marton, Buti and Pártai 1963) Pridham 1970, 35[AL] ("*Actinomyces finlayi*" Szabó, Marton, Buti and Pártai 1963, 209)

fin.lay′i. N.L. gen. masc. n. *finlayi* of Finlay, named for Alexander C. Finlay, discoverer of oxytetracycline.

Spore chains in Section *Rectiflexibiles* to *Spirales*. Short spore chains of 10 or more spores per chain are generally flexuous, crooked, hooked, or in imperfect spirals of only one or two turns; longer chains may form open spirals of three or four turns. Hooks and loops on short spore chains are not characteristic of *Retinaculiaperti* morphology. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; spirals are best developed on yeast-malt agar and oatmeal agar. Spore surface is hairy.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow to yellow-brown modified by green (grayish yellow to olive brown on yeast-malt agar and oatmeal agar; pale greenish yellow or yellow-green to moderate or dark olive green on salts-starch agar or glycerol-asparagine agar). Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigments are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose is utilized for growth. Significant growth also occurs on L-arabinose, D-xylose, and rhamnose, although growth on these carbon sources is less than on D-glucose. Utilization of sucrose is doubtful. No growth or only trace of growth on iso-inositol, D-mannitol, D-fructose, and raffinose.

Type strain shows the highest sequence similarity to: *S. clavifer*, DQ026670, 99.8%; *S. olivoviridis*, AB184227, 99.7%; *S. atroolivaceus*, AJ781320, 99.7%; *S. californicus*, AB184755, 99.6%; *S. mutomycini*, AB249951, 99.6%; *S. pluricolorescens*, DQ442540, 99.5%; *S. rubiginosohelvolus*, AB184240, 99.5%; *S. fulvorobeus*, AB184711, 99.5%; *S. lipmanii*, AB184148, 99.5%; *S. fimicarius*, AY999784, 99.5%; *S. sindenensis*, AB184759, 99.5%; *S. praecox*, AB184293, 99.5%; *S. flavofuscus*, AB249935, 99.5%; *S. badius*, AY999783, 99.5%; *S. mediolani*, AB184674, 99.5%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.5%; *S. anulatus*, DQ026637, 99.5%; *S. griseoplanus*, AY999894, 99.5%; *S. floridae*, AB184656, 99.5%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.5%; *S. alboviridis*, AB184256, 99.5%; *S. microflavus*, DQ445795, 99.5%; *S. griseinus*, AB184205, 99.5%; *S. cyaneofuscatus*, AB184860, 99.4%; *S. albovinaceus*, AB249958, 99.4%; *S. cinereorectus*, AB184646, 99.4%; *S. globisporus* subsp. *globisporus*, EF178686, 99.4%; *S. baarnensis*, EF178688, 99.4%; *S. acrimycini*, AY999889, 99.4%; *S. luridiscabiei*, AF361784, 99.4%; *S. griseolus*, AB184768, 99.3%; *S. candidus*, DQ026663, 99.3%; *S. griseus* subsp. *griseus*, AY207604, 99.3%; *S. argenteolus*, AB045872, 99.3%; *S. flavovirens*, DQ026635, 99.3%; *S. parvus*, DQ442537, 99.3%; *S. bacillaris*, AB184439, 99.2%; *S. flavogriseus*, AJ494864, 99.2%; *S. halstedii*, EF178695, 99.2%; *S. griseobrunneus*, AB249912, 99.1%; *S. albolongus*, AB184425, 99.1%; *S. celluloflavus*, AB184476, 99.1%; *S. pulveraceus*, AB184806, 99%; *S. nitrosporeus*, EF178680, 99%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1436, ATCC 23340, ATCC 23906, CBS 802.68, DSM 40218, HAMBI 1071, NBRC 13201, JCM 4216, JCM 4637, NCIMB 9834, NRRL B-12114, NRRL-ISP 5218, RIA 1162, VKM Ac-967.

Sequence accession no. (16S rRNA gene): AY999788.

173. **Streptomyces flaveolus** (Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 936^{AL} ("*Actinomyces flaveolus*" Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923, 368; "*Streptomyces flaveolus* subsp. *flaveolus*" Waksman *in* Pridham, Lyons and Seckinger 1965, 220)

fla.ve′o.lus. L. adj. *flavus* yellow; N.L. dim. masc. adj. *flaveolus* somewhat yellow.

Spore chains in Section *Spirales*, but short spore chains representative of Section *Retinaculiaperti* are also common. Mature spore chains generally have 10–50 spores per chain; shorter chains (3–10 spores) may be found. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (although sporulating aerial mycelium may be poorly developed on oatmeal agar or salts-starch agar). Spore surface is hairy with some tendency toward spines; carbon replica method suggests spiny spore surface. Coremia may form on salts-starch agar.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (White series also reported by one observer on salts-starch agar and glycerol-asparagine agar). Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. Yellow pigment found in medium in yeast-malt agar, glycerol-asparagine agar, and sometimes in other media. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on raffinose.

Type strain shows the highest sequence similarity to: *S. griseoflavus*, AJ781322, 99.5%; *S. fragilis*, AY999917, 99.3%; *S. collinus*, AB184123, 99.2%; *S. viridochromogenes*, DQ442555, 99.2%; *S. griseorubens*, AB184139, 99.2%; *S. ambofaciens*, M27245, 99.1%; *S. glaucescens*, AB184843, 99.1%; *S. paradoxus*, AB184628, 99.1%; *S. matensis*, AB184221, 99.1%; *S. variabilis*, DQ442551, 99.1%; *S. coelicoflavus*, AB184650, 99.1%; *S. griseoincarnatus*, AJ781328, 99.1%; *S. erythrogriseus*, AJ781328, 99.1%; *S. malachitofuscus*, AB184282, 99%; *S. labedae*, AB184704, 99%.

Source: not known.

Type strain: AS 4.1432, ATCC 19754, ATCC 3319, CBS 128.20, CBS 493.68, CCM 3171, BCRC 12489, CECT 3181, DSM 40061, HAMBI 893, NBRC 12768, NBRC 3408, NBRC 3715, IMET 40233, JCM 4032, JCM 4577, KCTC 9022, LMG 19328, NRRL B-1334, NRRL B-2688, NRRL-ISP 5061, RIA 1035, RIA 485, UNIQEM 141, VKM Ac-965.

Sequence accession no. (16S rRNA gene): AB184764.

174. **Streptomyces flaveus** (Cross, Lechevalier and Lechevalier 1963) Goodfellow, Williams and Alderson 1986a, 574^{VP} (Effective publication: Goodfellow, Williams and Alderson 1986a, 53.) (*Microellobosporia flavea* Cross, Lechevalier and Lechevalier 1963, 428)

fla.ve′us. N.L. masc. adj. *flaveus* presumably from *flavus* yellow.

Short straight spore chains (2–5). Spore surface is smooth. Spores borne on both the substrate and aerial mycelium. Forms extensively branched substrate and aerial mycelium. The aerial spore mass is gray; the reverse color is yellow brown. Does not form melanin pigments. Adenine, esculin, casein, hypoxanthine, starch, testosterone, tyrosine, and urea are degraded, but allantoin, arbutin, chitin, elastin, guanine, lecithin, pectin, xanthine, and xylan are not. Hydrogen sulfide is produced but nitrate is not reduced. L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, inulin, D-lactose, mannitol, D-mannose, melibiose, raffinose, L-rhamnose, salicin, sucrose, trehalose, and D-xylose are used as sole carbon sources, but adonitol, D-melezitose, and xylitol are not. Grows on DL-α-aminobutyric acid, L-arginine, L-cysteine, L-histidine, L-phenylalanine, potassium nitrate, L-serine, L-threonine, and L-valine, but not on L-hydroxyproline or L-methionine, as sole nitrogen source. Growth occurs at 10 and 37°C, but not at 4 or 45°C. Tolerant to phenol (0.1%, w/v) and sodium chloride (7%, w/v), but not to sodium azide (0.01%, w/v). Sensitive to rifampin and sodium chloride (10%, w/v). Does not show antimicrobial activity against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046^{T}, *Saccharomyces cerevisiae* CBS 1171^{T}, or *Streptomyces murinus* ISP 5091. Wall peptidoglycan contains LL-A_2pm as the major diamino acid. The organism has a type II phospholipid pattern (*sensu* Lechevalier et al., 1977) and contains major amounts of hexa- and octahydrogenated menaquinones with nine isoprene units (Collins et al., 1984).

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): 68–71.

Type strain: ATCC 15332, CBS 355.67, DSM 43153, IFM 1234, NBRC 12190, IMET 43554, LMG 19323, NCIMB 9587, NRRL B-16074, RIA 896, VKM Ac-1295, VKM Ac-633, KCC A-0035, JCM 3035.

Sequence accession no. (16S rRNA gene): DQ026643.

175. **Streptomyces flavidofuscus** Preobrazhenskaya 1986, 574^{VP} (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

fla.vi.do.fus′cus. L. adj. *flavidus* yellowish; L. adj. *fuscus* dark, tawny; N.L. masc. adj. *flavidofuscus* yellowish, tawny.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: starch-ammonia agar: aerial mycelium is velvety, creamy, yellow, sometimes poor; substrate mycelium is colorless; no diffusible pigment. On glycerol-nitrate agar, glycerol-asparagine agar: aerial mycelium is yellow; substrate mycelium is colorless or yellow; no diffusible pigment. On oatmeal agar: aerial mycelium is yellow; substrate mycelium is colorless or pink; no diffusible pigment. On organic agar 2: aerial mycelium is creamy, yellow; substrate mycelium and diffusible pigment are gray-brown. Melanoid pigments are found. Grows on fructose, sucrose, rhamnose, glucose, arabinose, raffinose,

mannitol, and inositol. Strains of this species produce the antibiotic echinomycin.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): 68–71.

Type strain: AS 4.1617, ATCC 43683, DSM 41473, NBRC 15404, INA 15719, JCM 6920, NRRL B-16366, VKM Ac-1209.

Sequence accession no. (16S rRNA gene): AY999914.

Further comments: according to Guo et al. (2008), *Streptomyces flavidofuscus* Preobrazhenskaya 1986 should be transferred to the genus *Nocardiopsis*. However, no formal proposition is made in the paper by Guo et al. (2008).

176. **Streptomyces flavidovirens** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 66[AL] ("*Actinomyces flavidovirens*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 90)

fla.vi.do.vi′rens. L. adj. *flavidus* yellowish; L. part. adj. *virens* being green; N.L. part. adj. *flavidovirens* being yellowish green.

Spore chains in Section *Retinaculiaperti* or *Rectiflexibiles*. Preponderance of very flexuous spore chains, some of which appear as imperfect or open spirals together with some straight or slightly flexuous chains makes this strain difficult to categorize in respect to spore chain morphology. The illustration accompanying the original description would place this species in Section *Spirales*, but regular spirals were not found by ISP observers. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The nearest matching color tab in the Yellow series is 2ba, pale yellow. Reverse side of colony with no distinctive pigments (colorless to pale yellow or light grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Traces of yellow pigment may or may not be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment, when present, is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. Reports vary on utilization of iso-inositol, D-fructose, rhamnose, and sucrose. No growth or only trace of growth with D-mannitol and raffinose.

Type strain shows the highest sequence similarity to: *S. helvaticus*, AB184367, 100%; *S. albidochromogenes*, AB249953, 100%; *S. chryseus*, AY999787, 100%; *S. enissocaesilis*, AB249930, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19900, ATCC 25451, CBS 684.69, BCRC 13761, DSM 40150, NBRC 13039, IMET 43744, INA 12287, JCM 4474, NRRL B-2708, NRRL-ISP 5150, RIA 1231, VKM Ac-1771.

Sequence accession no. (16S rRNA gene): AB184270.

177. **Streptomyces flaviscleroticus** (*ex* Pridham 1970) Goodfellow, Williams and Alderson 1986a, 574[VP] (Effective publication: Goodfellow, Williams and Alderson 1986d, 59.)

fla.vi.scle.ro′ti.cus. L. adj. *flavus* yellow; N.L. neut. n. *sclerotium* sclerotium; N.L. masc. adj. *flaviscleroticus* yellow sclerotium, referring to yellow and ability to form sclerotia.

Spore chain morphology: Section not determined. Aerial mycelium is poorly developed or absent on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Rare spore chains on yeast-malt agar or on glycerol-asparagine agar are reported to be straight or flexuous. The original description by Thirumalachar reports irregular spirals. Spore surface is not determined.

One of three observers reports "globula sporangia" on yeast-malt agar, oatmeal agar, and salts-starch agar, and sclerotia on yeast-malt agar. Fragmentation of substrate mycelium into spore-like bodies is also recorded by this observer.

Color of colony is not determined. Aerial mycelium is not produced on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Reverse side of colony is olive brown to strong brown on yeast-malt agar; greenish yellow on oatmeal agar; grayish yellow, orange yellow, or moderate yellow on salts-starch agar and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of sucrose is doubtful; no growth or only traces of growth with iso-inositol and raffinose.

For sequence similarity, see type strain of *Streptomyces minutiscleroticus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19347, AS 4.1071, CBS 658.72, BCRC 12108, CMI 117723, DSM 40270, DSM 43152, NBRC 12998, NBRC 13357, NBRC 14019, NBRC 15148, IMET 43617, JCM 3100, JCM 4751, KCC A-0100, LMG 19886, NCIB (now NCIMB) 11008, NRRL B-12173, NRRL-ISP 5270, PCM 2303, RIA 1318, RIA 883.

Sequence accession no. (16S rRNA gene): AB184634.

Further comments: according to Goodfellow et al. (1986a), the species *Streptomyces flaviscleroticus* (*ex* Pridham 1970) Goodfellow et al. 1986a is a synonym of the species *Chainia flava* Thirumalachar and Sukapure 1964. However, according to Rule 51b (2) of the *Bacteriological Code* (1990 Revision), the transfer of *Chainia flava* Thirumalachar and Sukapure 1964 in the genus *Streptomyces* Waksman and Henrici 1943 as *Streptomyces flaviscleroticus* (*ex* Pridham 1970) Goodfellow et al. 1986a sp. nov., nom. rev. is illegitimate.

According to Lanoot et al. (2005b), *Streptomyces flaviscleroticus* (*ex* Pridham 1970) Goodfellow et al. 1986a is a later heterotypic synonym of *Streptomyces minutiscleroticus* (Thirumalachar 1965) Pridham 1970 emend. Lanoot et al. 2005b.

178. **Streptomyces flavofungini** (*ex* Uri and Békési 1958) Szabó and Preobrazhenskaya 1986, 574[VP] (Effective publication: Szabó and Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ["*Actinomyces flavofungini*" (Uri and Békési 1958) Szabó and Preobrazhenskaya 1962]

fla.vo.fun.gi′ni. L. adj. *flavus* golden yellow, reddish yellow; L. adj. *funginus* of a mushroom, pertaining to a mushroom; N.L. adj. *flavofungini* yellow and from a mushroom.

Spore chains in Section *Rectiflexibiles*, but sporulation is poor or absent on most media. Absence of sporulation is also mentioned in the original description for this strain. ISP observers record short to long spore chains on oatmeal agar and salts-starch agar but not on yeast-malt agar or glycerol-asparagine agar. Spore chains may also be seen on carbon-utilization media. Spore surface is smooth.

Color of colony: aerial mass color in the White or Yellow color series on salts-starch agar. Nearest matching color tab in the Yellow color series is 1cb, pale yellow green. Reverse side of colony is yellow to greenish yellow or light olive or light olive brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: two of three observers report dark pigments in peptone-yeast-iron agar. No melanoid pigments are seen in tyrosine agar or tryptone-yeast broth. Yellow or pale greenish yellow pigment is sometimes found in the medium in oatmeal agar, salts-starch agar, or glycerol-asparagine agar, or pigment may be absent in these media.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Utilization of rhamnose is doubtful. No growth or only traces of growth with sucrose.

Type strain shows the highest sequence similarity to: *S. fulvissimus*, AB184434, 99.7%; *S. alboflavus*, EF178699, 99%.

Source: not known.

Type strain: SA-IX-3, ATCC 27430, CBS 411.59, CBS 672.72, DSM 40366, NBRC 13371, JCM 4753, NRRL B-12307, NRRL-ISP 5366, RIA 1332, VKM Ac-1179.

Sequence accession no. (16S rRNA gene): AB184359.

179. **Streptomyces flavofuscus** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Preobrazhenskaya 1986, 574[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces globisporus* var. *flavofuscus*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 81; *Streptomyces globisporus* subsp. *flavofuscus* Pridham, Hesseltine and Benedict 1958, 59)

fla.vo.fus′cus. L. adj. *flavus* yellow; L. adj. *fuscus* dark, tawny; N.L. masc. adj. *flavofuscus* yellow, tawny.

Spore chains are straight (*Rectiflexibiles*); spores are smooth. On mineral agar 1, glycerol-nitrate agar: aerial mycelium is mealy, yellow, green-yellow; substrate mycelium and diffusible pigment are gray-brownish, gray-brown. On oatmeal agar: aerial mycelium is yellow; substrate mycelium is colorless; no diffusible pigment. On synthetic agar Korenjako (Kuchaeva et al., 1960): aerial mycelium is yellow; substrate mycelium is dark green; no diffusible pigment. On organic agar 2: aerial mycelium is yellow; substrate mycelium and diffusible pigment are yellow-gray-brown, gray-brown. Melanoid pigments are not formed. Antibiotic: not produced.

Type strain shows the highest sequence similarity to: *S. rubiginosohelvolus*, AB184240, 100%; *S. praecox*, AB184293, 100%; *S. griseinus*, AB184205, 100%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. acrimycini*, AY999889, 100%; *S. griseoplanus*, AY999894, 100%; *S. anulatus*, DQ026637, 100%; *S. flavofuscus*, AB249935, 100%; *S. sindenensis*, AB184759, 100%; *S. fimicarius*, AY999784, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. microflavus*, DQ445795, 99.9%; *S. alboviridis*, AB184256, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. globisporus* subsp. *globisporus*, EF178686, 99.9%; *S. baarnensis*, EF178688, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. fulvorobeus*, AB184711, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. albovinaceus*, AB249958, 99.9%; *S. parvus*, DQ442537, 99.8%; *S. californicus*, AB184755, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. luridiscabiei*, AF361784, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. flavogriseus*, AJ494864, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. floridae*, AB184656, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. bacillaris*, AB184439, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. atroolivaceus*, AJ781320, 99.5%; *S. clavifer*, DQ026670, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. yanii*, AB006159, 99.4%; *S. atratus*, DQ026638, 99.3%; *S. gelaticus*, DQ026636, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. celluloflavus*, AB184476, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. mutomycini*, AB249951, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. spiroverticillatus*, AB184814, 99.2%; *S. candidus*, DQ026663, 99.1%; *S. mauvecolor*, AB184532, 99%; *S. cremeus*, AB184124, 99%.

180. **Streptomyces flavogriseus** (Duché 1934) Waksman *in* Waksman and Lechevalier 1953, 55[AL] ("*Actinomyces flavogriseus*" Duché 1934, 341)

fla.vo.gri′se.us. L. adj. *flavus* yellow; N.L. adj. *griseus* gray; N.L. masc. adj. *flavogriseus* yellowish gray.

Spore chains in Section *Rectiflexibiles*. Mature spore chains have 3–10, or often more than 10 spores per chain; long chains are not common. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is

strong yellow or orange-yellow on yeast-malt agar, grayish yellow to olive brown on oatmeal agar, greenish yellow on salts-starch agar; reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment, or only a trace of yellow, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with iso-inositol, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. flavovirens*, DQ026635, 100%; *S. nitrosporeus*, EF178680, 99.7%; *S. fimicarius*, AY999784, 99.7%; *S. praecox*, AB184293, 99.7%; *S. cinereorectus*, AB184646, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. flavofuscus*, AB249935, 99.7%; *S. anulatus*, DQ026637, 99.7%; *S. halstedii*, EF178695, 99.6%; *S. pluricolorescens*, DQ442540, 99.6%; *S. sindenensis*, AB184759, 99.6%; *S. mediolani*, AB184674, 99.7%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.6%; *S. albovinaceus*, AB249958, 99.6%; *S. rubiginosohelvolus*, AB184240, 99.6%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.6%; *S. griseinus*, AB184205, 99.6%; *S. badius*, AY999783, 99.6%; *S. argenteolus*, AB045872, 99.6%; *S. acrimycini*, AY999889, 99.6%; *S. griseoplanus*, AY999894, 99.6%; *S. luridiscabiei*, AF361784, 99.5%; *S. microflavus*, DQ445795, 99.5%; *S. cyaneofuscatus*, AB184860, 99.5%; *S. parvus*, DQ442537, 99.5%; *S. californicus*, AB184755, 99.5%; *S. lipmanii*, AB184148, 99.5%; *S. fulvorobeus*, AB184711, 99.5%; *S. alboviridis*, AB184256, 99.5%; *S. floridae*, AB184656, 99.4%; *S. globisporus* subsp. *globisporus*, EF178686, 99.4%; *S. griseus* subsp. *griseus*, AY207604, 99.4%; *S. baarnensis*, EF178688, 99.4%; *S. pulveraceus*, AB184806, 99.3%; *S. bacillaris*, AB184439, 99.3%; *S. olivoviridis*, AB184227, 99.2%; *S. atroolivaceus*, AJ781320, 99.2%; *S. finlayi*, AY999788, 99.2%; *S. yanii*, AB006159, 99.2%; *S. celluloflavus*, AB184476, 99.1%; *S. griseobrunneus*, AB249912, 99.1%; *S. gelaticus*, DQ026636, 99.1%; *S. spiroverticillatus*, AB184814, 99.1%; *S. sanglieri*, AB249945, 99.1%; *S. clavifer*, DQ026670, 99.1%; *S. albolongus*, AB184425, 99.1%; *S. atratus*, DQ026638, 99.1%; *S. cremeus*, AB184124, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 25452, CBS 101.34, CBS 685.69, BCRC 13440, CECT 3327, DSM 40323, NBRC 13040, IMET 43576, JCM 4475, KCTC 9778, NRRL B-1671, NRRL-ISP 5323, RIA 1232, VKM Ac-1325.

Sequence accession no. (16S rRNA gene): AJ494864.

181. **Streptomyces flavopersicus** (Oliver, Goldstein, Bower, Holper and Otto 1961) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces flavopersicus*" Oliver, Goldstein, Bower, Holper and Otto 1961, 495; *Streptoverticillium flavopersicum* Locci, Baldacci and Petrolini Baldan 1969, 41)

fla.vo.per'si.cus. L. adj. *flavus* yellow; L. n. *persicus* peach; N.L. masc. adj. *flavopersicus* of yellow peach.

Spore chains in Section *Verticillati*. Umbellate monoverticillate (biverticillate); individual spore chains may form hooks, loops, or primitive spirals. Mature spore chains generally have 10–50 spores per chain; but shorter chains of 3–10 spores are also found. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed weakly after prolonged cultivation in peptone-yeast-iron agar. No pigment found in medium, or very faint color in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and iso-inositol are utilized for growth. No growth or only trace of growth on L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose. Utilization of D-fructose is doubtful.

For sequence similarity, see type strain of *Streptomyces netropsis.*

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19756, JCM 4307, JCM 4370, NBRC 12769, NRRL 2820, UNIQEM 142.

Sequence accession no. (16S rRNA gene): AB249911.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces flavopersicus* is proposed as a *nomen revictum* (basonym: "*Streptomyces flavopersicus*" Oliver et al. 1961).

According to Labeda (1996) and Hatano et al. (2003), *Streptomyces flavopersicus* (Oliver et al. 1961) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces netropsis* (Finlay et al. 1951) Witt and Stackebrandt 1991.

182. **Streptomyces flavotricini** (Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 60[AL] ("*Actinomyces flavotricini*" Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 49)

fla.vo.tri.ci'ni. L. adj. *flavus* yellow; Gr. n. *thrix* the hair; N.L. *flavotricini* (*sic*) of yellow hair, probably referring to yellow diffusible pigment and formation of a streptothricin-like antibiotic.

Spore chains in Section *Rectiflexibiles.* Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but not on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast broth. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose is utilized for growth; doubtful utilization of D-fructose. No growth or only trace of growth on

L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. polychromogenes*, AB184292, 99.7%; *S. racemochromogenes*, DQ026656, 99.7%; *S. globosus*, AJ781330, 99.4%; *S. toxytricini*, DQ442548, 99.3%; *S. katrae*, AB184409, 99.2%; *S. cinnamonensis*, AB184707, 99.2%; *S. virginiae*, D85119, 99%; *S. tanashiensis*, AJ781362, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19757, ATCC 23621, CBS 495.68, BCRC 13762, DSM 40152, NBRC 12770, IMET 42057, INA 11669/58, JCM 4371, NRRL B-5419, NRRL-ISP 5152, RIA 1037, UNIQEM 143, VKM Ac-1277.

Sequence accession no. (16S rRNA gene): AB184132.

183. **Streptomyces flavovariabilis** (*ex* Korenyako and Nikitina *in* Krasil'nikov 1965) Sveshnikova 1986, 574[VP] (Effective publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces flavovariabilis*" Korenyako and Nikitina *in* Krasil'nikov 1965; "*Streptomyces flavovariabilis*" Pridham 1970)

fla.vo.va.ri.a'bi.lis L. adj. *flavus* yellow; L. adj. *variabilis* variable; N.L. masc. adj. *flavovariabilis* yellow, variable.

Spore chains are spiral (*Spirales*); spore surface is spiny or smooth. On mineral agar 1, oatmeal agar: aerial mycelium is whitish, creamy to pale pink; substrate mycelium is grayish green or yellowish green; diffusible pigment weak or not extant. On starch-ammonia agar: aerial mycelium is poor, whitish; substrate mycelium is pale olive; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is whitish to creamy or grayish; substrate mycelium is greenish gray; diffusible pigment not extant or weak, greenish-grayish. On glycerol-asparagine agar: aerial mycelium is poor, white; substrate mycelium is colorless to pale olive; no diffusible pigment. On organic agar 2: aerial mycelium is pale to creamy; substrate mycelium is dark olive or brown; diffusible pigment is brown. Melanoid pigment is formed.

Good growth on glucose, sucrose, arabinose, rhamnose, xylose, fructose, raffinose, and mannitol. Color of substrate mycelium changes to red under acidic conditions. Blue pigment is very unstable and degenerated quickly, forming dirty yellow, dirty green and other similar pigments which were also found on mycelia of *Streptomyces iakyrus* (Blinov et al., 1975; Machenko et al., 1970). Exhibits anti-bacterial and anti-tumor activity; grows on Czapek's solution agar.

Type strain shows the highest sequence similarity to: *S. pseudovenezuelae*, AB184233, 99.2%; *S. novaecaesareae*, AB184357, 99.1%; *S. cacaoi* subsp. *asoensis*, DQ026644, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 43684, DSM 41479, INMI 702, JCM 9089, NBRC 100764, NRRL B-16367, VKM Ac-141.

Sequence accession no. (16S rRNA gene): EF178691.

184. **Streptomyces flavovirens** (Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 940[AL] ("*Actinomyces flavovirens*" Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923, 352)

fla.vo.vi'rens. L. adj. *flavus* golden yellow, reddish yellow; L. v. *vireo* to be green; N.L. part adj. *flavovirens* yellow and becoming green.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony is colorless or characteristic grayed yellow modified by green on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. Pigments other than melanoids not formed, or some yellow pigment may be produced on oatmeal agar and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and rhamnose are utilized for growth. No growth on sucrose, iso-inositol, or raffinose; trace of growth on D-fructose.

Type strain shows the highest sequence similarity to: *S. flavogriseus*, AJ494864, 100%; *S. sindenensis*, AB184759, 99.7%; *S. pluricolorescens*, DQ442540, 99.7%; *S. fimicarius*, AY999784, 99.7%; *S. cinereorectus*, AB184646, 99.7%; *S. griseinus*, AB184205, 99.7%; *S. badius*, AY999783, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. praecox*, AB184293, 99.7%; *S. flavofuscus*, AB249935, 99.7%; *S. nitrosporeus*, EF178680, 99.7%; *S. mediolani*, AB184674, 99.7%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.7%; *S. griseoplanus*, AY999894, 99.7%; *S. rubiginosohelvolus*, AB184240, 99.7%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.7%; *S. anulatus*, DQ026637, 99.7%; *S. acrimycini*, AY999889, 99.6%; *S. globisporus* subsp. *globisporus*, EF178686, 99.6%; *S. albovinaceus*, AB249958, 99.6%; *S. cyaneofuscatus*, AB184860, 99.6%; *S. fulvorobeus*, AB184711, 99.6%; *S. fulvorobeus*, AB184711, 99.6%; *S. alboviridis*, AB184256, 99.9%; *S. lipmanii*, AB184148, 99.6%; *S. luridiscabiei*, AF361784, 99.5%; *S. baarnensis*, EF178688, 99.5%; *S. griseus* subsp. *griseus*, AY207604, 99.5%; *S. microflavus*, DQ445795, 99.5%; *S. floridae*, AB184656, 99.5%; *S. californicus*, AB184755, 99.5%; *S. parvus*, DQ442537, 99.5%; *S. pulveraceus*, AB184806, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. yanii*, AB006159, 99.3%; *S. olivoviridis*, AB184227, 99.3%; *S. atroolivaceus*, AJ781320, 99.3%; *S. finlayi*, AY999788, 99.3%; *S. sanglieri*, AB249945, 99.2%; *S. albolongus*, AB184425, 99.2%; *S. spiroverticillatus*, AB184814, 99.2%; *S. griseobrunneus*, AB249912, 99.2%; *S. clavifer*, DQ026670, 99.2%; *S. celluloflavus*, AB184476, 99.2%; *S. atratus*, DQ026638, 99.1%; *S. gelaticus*, DQ026636, 99.1%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99%; *S. mutomycini*, AB249951, 99%; *S. cremeus*, AB184124, 99%.

Sequence accession no. (16S rRNA gene): DQ026635.

Further comments: according to Lanoot et al. (2005b), *Streptomyces flavovirens* (Waksman 1923) Waksman and Henrici 1948 emend. Lanoot et al. 2005b is an earlier heterotypic synonym of *Streptomyces nigrifaciens* Waksman (1961).

185. **Streptomyces flavoviridis** (*ex* Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Preobrazhenskaya 1986, 574[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces flavoviridis*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957)

fla.vo.vi′ri.dis. L. adj. *flavus* yellow; L. adj. *viridis* green; N.L. masc. adj. *flavoviridis* yellow-green.

Spore chains in Section *Spirales* (young spore chains may resemble *Retinaculiaperti*). Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is hairy.

Color of colony: aerial mass color in the Gray or Green series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; color tabs selected by observers are all light olive gray or light olive brown. Reverse side of colony with no distinctive pigments (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast broth. No other pigment in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose or raffinose.

Type strain shows the highest sequence similarity to: *S. pilosus*, AB184161, 100%; *S. violaceus*, AB184315, 99.3%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.3%; *S. janthinus*, AB184851, 99.3%; *S. lomondensis*, AB184673, 99.2%; *S. geysiriensis*, DQ442501, 99.2%; *S. minutiscleroticus*, EF178696, 99.2%; *S. roseoviolaceus*, AJ399484, 99.2%; *S. ghanaensis*, AY999851, 99.2%; *S. luteogriseus*, AB184379, 99.2%; *S. djakartensis*, AB184657, 99.1%; *S. plicatus*, AB184291, 99.1%; *S. rochei*, AB184237, 99.1%; *S. vinaceusdrappus*, AY999929, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. hawaiiensis*, AB184143, 99.1%; *S. atrovirens*, DQ026672, 99.1%; *S. arenae*, AB249977, 99%; *S. calvus*, AB184329, 99%; *S. tuirus*, AB184690, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19759, ATCC 19903, CBS 497.68, BCRC 11474, DSM 40153, NBRC 12772, IMET 42058, INA 2314/53, JCM 4372, NRRL-ISP 5153, RIA 1039, UNIQEM 145, VKM Ac-754.

Sequence accession no. (16S rRNA gene): AB184842.

186. **Streptomyces flocculus** (Duché 1934) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 955[AL] ("*Actinomyces flocculus*" Duché 1934, 300)

floc′cu.lus. L. n. *floccus* a flock of wool; N.L. dim. masc. adj. *flocculus* like a small flock of wool.

Spore chains in Section *Spirales*. Spiral spore chains are usually formed on oatmeal agar; spirals of two or more turns may be formed or short chains of only 3–10 spores may form loops, partial spirals, or hooks. Sporulating aerial mycelium is usually poorly developed on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar so that spirals and hooks may be sparse or absent. The weak growth of this strain on most media was noted by Duché in his original description. Spore surface is smooth.

Color of colony: aerial mass color in the White or Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The most representative color tab in the Yellow color series is 2ba (pale yellow). Reverse side of colony with no distinctive pigments (colorless or pale grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and sucrose are utilized for growth. Utilization of rhamnose and raffinose is doubtful.

Type strain shows the highest sequence similarity to: *S. rangoonensis*, AB184295, 99.9%; *S. gibsonii*, AB184663, 99.9%; *S. almquistii*, AB184258, 99.9%; *S. albus* subsp. *albus*, AJ621602, 99.8%.

Source: isolated from soil from Florida.

DNA G+C content (mol%): not known.

Type strain: DSM 40938, NBRC 15405, JCM 5068, NCIMB 12830, NRRL 2423.

Sequence accession no. (16S rRNA gene): AB184656.

188. **Streptomyces fluorescens** (Krasil'nikov 1958) Pridham 1970, 15[AL] ("*Actinomyces fluorescens*" Krasil'nikov 1958, 258)

flu.o.res′cens. N.L. v. *fluoresco* to fluoresce; N.L. part. adj. *fluorescens* fluorescing, referring to the yellow fluorescent pigment produced by the organism.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, and salts-starch agar; White or Yellow color series on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; grayed orange-yellow to olive brown on yeast-malt agar). Reverse pigment is not pH-sensitive or is changed only slightly from yellow-brown to yellow-green, with addition of 0.05 M NaOH.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. A small amount of yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and tryptone-yeast broth. This pigment, when present, is only slightly pH-sensitive, changing from yellow-brown to yellow-green with addition of 0.05 NaOH.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose. The original description for this species states that rhamnose is not utilized, noting that this is one difference between *A. fluorescens* and other species in the fluorescent group. However, all of the three ISP observers recorded good growth on rhamnose, equivalent to growth on D-glucose.

For sequence similarity, see type strain of *Streptomyces anulatus*.

DNA G+C content (mol%): not known.

Type strain: ATCC 15860, ATCC 23907, CBS 803.68, BCRC 11475, CECT 3130, DSM 40203, NBRC 12861, INMI 592, JCM 4373, LMG 8579, NCIMB 9851, NRRL B-2873, NRRL-ISP 5203, RIA 1154, RIA 647, VKM Ac-147.

Sequence accession no. (16S rRNA gene): AB184199.

Further comments: according to Lanoot et al. (2005b), *Streptomyces fluorescens* (Krasil'nikov 1958) Pridham 1970 is a later heterotypic synonym of *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953 emend. Lanoot et al. 2005b.

189. **Streptomyces fradiae** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 954[AL] emend. Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2004, 88.) ["*Actinomyces fradii*" (*sic*) Waksman and Curtis 1916, 125; "*Streptomyces fradii*" (*sic*) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 954; "*Streptomyces fradiae* subsp. *fradiae*" Waksman and Curtis *in* Pridham, Lyons and Seckinger 1965, 222]

fra.di′a.e. N.L. gen. n. *fradiae* of Fradia, a patronymic.

Spore chains in Section *Retinaculiaperti* with characteristic range from straight to spiral spore chains. Straight or flexuous spore chains are most common on yeast-malt agar; *Retinaculiaperti* morphology, including open spirals, best developed on oatmeal agar and salts-starch agar. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose. Variable reports on growth with D-xylose.

Type strain shows the highest sequence similarity to: *S. coeruleoprunus*, AB184651, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 10745, ATCC 19760, CBS 498.68, CCM 3174, BCRC 12196, CECT 3197, DSM 40063, HAMBI 965, HUT 6095, IFM 1030, NBRC 12773, NBRC 3718, IMET 42051, IMI 061202, JCM 4133, JCM 4579, KCTC 9760, NCIMB 11005, NCIMB 8233, NRRL B-1195, NRRL-ISP 5063, PCM 2330, RIA 1040, RIA 97, UNIQEM 146, VKM Ac-150, VKM Ac-151, VKM Ac-152, VKM Ac-764.

Sequence accession no. (16S rRNA gene): DQ026630.

Further comments: according to Lanoot et al. (2004), *Streptomyces fradiae* (Waksman and Curtis 1916) Waksman and Henrici 1948 is an earlier heterotypic synonym of *Streptomyces roseoflavus* Arai 1951.

190. **Streptomyces fragilis** Anderson, Ehrlich, Sun and Burkholder 1956, 105[AL]

fra′gi.lis. L. masc. adj. *fragilis* fragile.

Spore chains of atypical *Retinaculiaperti* type. Poor growth on Czapek's solution agar; produces *O*-diazoacetyl-L-serine (azaserine), an anti-bacterial, anti-fungal, anti-protozoal, and anti-tumor antibiotic; inhibited by streptomycin; NaCl tolerance: >4%, but <7%.

Type strain shows the highest sequence similarity to: *S. coelicoflavus*, AB184650, 99.4%; *S. flaveolus*, AB184764, 99.3%; *S. matensis*, AB184221, 99%; *S. eurythermus*, D63870, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23908, CBS 804.68, BCRC 13654, DSM 40044, HAMBI 1083, HAMBI 1090, NBRC 12862, IMET 43575, JCM 4187, JCM 4638, NCIMB 9795, NRRL 2424, NRRL-ISP 5044, RIA 1111, VKM Ac-1773.

Sequence accession no. (16S rRNA gene): AY999917.

191. **Streptomyces fulvissimus** (Jensen 1930) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 946[AL] ("*Actinomyces fulvissimus*" Jensen 1930, 66)

ful.vis′si.mus. L. sup. masc. adj. *fulvissimus* very yellow.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally contain 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar, but sporulating aerial mycelium may be poorly developed or absent on oatmeal agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; white aerial mycelium may also be present. Nearest matching color tabs in the Red color series are 3ea, light orange yellow; 5ca and 7ca, light yellowish pink; and 4ea, moderate yellowish pink. Reverse side of colony with distinctive reddish orange pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar or tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Carbon utilization: D-glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Reports vary on the utilization of D-xylose, and the utilization of sucrose and rhamnose is doubtful.

Type strain shows the highest sequence similarity to: *S. flavofungini*, AB184359, 99.7%; *S. alboflavus*, EF178699, 99.3%; *S. variegatus*, AJ781371, 99.1%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB184434.

192. **Streptomyces fulvorobeus** Vinogradova and Preobrazhenskaya 1986, 574[VP] (Effective publication: Vinogradova and Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

ful.vo.ro′be.us. L. adj. *fulvus* reddish yellow; L. adj. *robeus* reddish brown; N.L. masc. adj. *fulvorobeus* reddish yellow, reddish brown.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1, glycerol-nitrate agar: aerial mycelium is creamy, yellow, grayish yellow; substrate mycelium is gray-brownish yellow, yellow-gray-brown. On starch ammonia agar, glycerol-asparagine agar, oatmeal agar: aerial mycelium is white-yellow, yellow; substrate mycelium is colorless; no diffusible pigment. On organic agar 2: aerial mycelium is whitish or absent; substrate mycelium is colorless; no diffusible pigment. Melanoid pigments are not formed. Grows on glucose, maltose, sucrose, and arabinose; no growth on mannitol, xylose, inositol, rhamnose, or galactose.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. microflavus*, DQ445795, 100%; *S. lipmanii*, AB184148, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. alboviridis*, AB184256, 100%; *S. luridiscabiei*, AF361784, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. floridae*, AB184656, 99.9%; *S. praecox*, AB184293, 99.9%; *S. anulatus*, DQ026637, 99.9%; *S. pluricolorescens*, DQ442540, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. griseinus*, AB184205, 99.8%; *S. badius*, AY999783, 99.8%; *S. rubiginosohelvolus*, AB184240, 99.8%; *S. sindenensis*, AB184759, 99.8%; *S. mediolani*, AB184674, 99.8%; *S. californicus*, AB184755, 99.8%; *S. globisporus* subsp. *globisporus*, EF178686, 99.8%; *S. parvus*, DQ442537, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. flavovirens*, DQ026635, 99.6%; *S. finlayi*, AY999788, 99.5%; *S. flavogriseus*, AJ494864, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. yanii*, AB006159, 99.4%; *S. atroolivaceus*, AJ781320, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. pulveraceus*, AB184806, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. albolongus*, AB184425, 99.4%; *S. clavifer*, DQ026670, 99.3%; *S. nitrosporeus*, EF178680, 99.3%; *S. cavourensis*

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 41455, NBRC 15897, INMI 34-280, JCM 9090, VKM Ac-158.

Sequence accession no. (16S rRNA gene): AB184711.

193. **Streptomyces fumanus** (Sveshnikova 1957) *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957 Pridham, Hesseltine and Benedict 1958, 67[AL] ["*Actinomyces fumanus*" Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 61; "*Actinomyces fumarius*" (*sic*) Danga and Gottlieb 1959, 43]

fu.ma′nus. N.L. masc. adj. *fumanus* smoky, probably referring to the color of the vegetative mycelium of the organism.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar and glycerol-asparagine agar; Red or sometimes Yellow color series on oatmeal agar and salts-starch agar. Reverse side of colony is light grayish yellow may or may not change to dark brown on salts-starch agar and glycerol-asparagine agar or to orange-yellow or strong brown on yeast-malt agar and oatmeal agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment (or only a trace of yellow or greenish yellow) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only traces of growth on iso-inositol and sucrose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19904, ATCC 25454, CBS 687.69, BCRC 12058, DSM 40154, NBRC 13042, INA 10256/54, JCM 4477, NRRL B-3898, NRRL B-5420, NRRL-ISP 5154, RIA 1234, VKM Ac-1845.

Sequence accession no. (16S rRNA gene): AB184273.

194. **Streptomyces fumigatiscleroticus** (*ex* Pridham 1970) Goodfellow, Williams and Alderson 1986a, 59[VP] (Effective publication: Goodfellow, Williams and Alderson 1986d, 59.)

fu.mi.ga.ti.scle.ro′ti.cus. L. part. adj. *fumigatus* smoked; N.L. neut. n. *sclerotium* sclerotium; N.L. masc. adj. *fumigatiscleroticus* smoked sclerotium, referring to smoke color and ability to form sclerotia.

Produces spiral spore chains and shows brownish-black crusty growth; extensively branched substrate and aerial mycelium. Produces sclerotia. Melanin pigments are not formed. Degrades gelatin, starch, urea, and xanthine. Nitrate is reduced but hydrogen sulfide is not produced. L-Arabinose, glucose, lactose, maltose, D-mannitol, mannose, sorbitol, sucrose, and D-xylose are used as sole carbon sources but dulcitol, galactose, glycerol, inulin, *myo*-inositol, L-rhamnose, salicin, and sucrose are not. Acid is produced from D-lactose, D-mannitol, melibiose, methyl α-D-glucoside, raffinose, L-rhamnose, D-sorbitol, and D-xylose but not from adonitol, dulcitol, *meso*-erythritol, *myo*-inositol, or sucrose. Grows at 42°C but not at 10°C. Shows antimicrobial activity against *Bacillus subtilis*, *Escherichia coli*, and *Staphylococcus aureus* but not against *Candida albicans*, *Cryptococcus neoformans*, or *Saccharomyces cerevisiae*.

Type strain shows the highest sequence similarity to: *S. poonensis*, DQ445792, 99.3%; *S spiralis*, EF178683, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19345, CBS 639.66, BCRC 12344, CMI 117720, DSM 43154, NBRC 12999, KCC A-0101, JCM 3101, NCIMB 11004, NRRL B-3856, RIA 884.

Sequence accession no. (16S rRNA gene): DQ442499.

Further comments: according to Goodfellow et al. (1986d), the species *Streptomyces fumigatiscleroticus* (*ex* Pridham 1970) Goodfellow et al. 1986a is a synonym of the species *Chainia fumigata* Thirumalachar et al. 1966. However, according to Rule 51b(2) of the *Bacteriological Code* (1990 Revision) the transfer of *Chainia fumigata* Thirumalachar et al. 1966 in the genus *Streptomyces* Waksman and Henrici 1943 as *Streptomyces fumigatiscleroticus* (*ex* Pridham 1970) Goodfellow et al. 1986a sp. nov., nom. rev. is illegitimate.

195. **Streptomyces galbus** Frommer 1959, 195[AL]

gal′bus. L. masc. adj. *galbus* greenish yellow.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Spirals may be open coils of several turns, tight spirals at the ends of flexuous spore chains or imperfect spirals and loops at the ends of spore chains suggesting *Retinaculiaperti* morphology. Spore chains are moderately long with 10–50, or often more than 50, spores per chain. Spore surface is smooth to warty. Surface irregularities suggesting very small warts are characteristic.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar and oatmeal agar and in the Yellow color series or Gray color series on salts-starch agar and glycerol-asparagine agar. Gray color is represented by tabs 2fe (medium gray) or 3fe (light brownish gray) on all media; and 1ba or 2ba (pale yellow) or 1½db (pale grayish yellow) on salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (yellow to yellow-brown or olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. Yellow soluble pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not a pH indicator.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. Only traces of growth comparable to growth on carbon-free control is found on sucrose, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. longwoodensis*, AB184580, 99.9%; *S. bungoensis*, AB184696, 99.7%; S. *capoamus*, AB045877, 99.5%; *S. corchorusii*, AB184267, 99.3%; *S. olivaceoviridis*, AB184288, 99.2%; *S. canarius*, AB184396, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23910, CBS 831.68, BCRC 12166, DSM 40089, NBRC 12864, IMET 42937, JCM 4222, JCM 4639, NCIMB 13005, NRRL B-2283, NRRL-ISP 5089, RIA 1121, VKM Ac-165.

Sequence accession no. (16S rRNA gene): X79852.

196. **Streptomyces galilaeus** Ettlinger, Corbaz and Hütter 1958a, 356[AL]

ga.li.la′e.us. L. masc. adj. *galilaeus* of or belonging to Galilee, a Province in Palestine, apparently the source of the soil (Newi Yusha, Israel) from which the organism was isolated.

Spore chains in Section *Spirales*. Open spirals with moderately long chains of 10 to 50 or more spores are found on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; shorter flexuous spore chains are usually found on yeast-malt agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs for 14- to 21-d-old cultures are 7ih, grayish pink, and 7fe, pale purple. Observers do not agree on the nearest matching color tab from the Gray color series for the aerial mass on salts-starch agar or glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow to yellowish brown or olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Two of three observers note that the yellowish color of the reverse side of the mycelium is changed to yellowish pink or faint pink by the addition of 0.05 M NaOH.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When a faint yellow pigment is found, it shows the same color changes noted for the reverse mycelium pigment when 0.05 M NaOH is added.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth. No growth or only traces of growth with D-mannitol.

Type strain shows the highest sequence similarity to: *S. bobili*, AB249925, 100%; *S. aureocirculatus*, AB184260, 99.5%; *S. phaeoluteigriseus*, AJ391815, 99.5%; *S. resistomycificus*, AB184166, 99.5%; *S. novaecaesareae*, AB184357, 99.4%; *S. chartreusis*, AB184839, 99.3%; *S. pseudovenezuelae*, AB184233, 99.3%; *S. prunicolor*, DQ026659, 99%.

Source: soil from Palestine.

DNA G+C content (mol%): not known.

Type strain: ATCC 14969, CBS 701.72, BCRC 11828, CCT 4839, DSM 40481, NBRC 13400, JCM 4231, JCM 4757, KCTC 1921, NRRL 2722, NRRL-ISP 5481, RIA 1361, VKM Ac-729.

Sequence accession no. (16S rRNA gene): AB045878.

197. **Streptomyces gancidicus** Suzuki 1957, 538[AL]

gan.ci′di.cus. N.L. n. *gancidinum* gancidin name of an antibiotic; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *gancidicus* belonging to gancidin.

Moderate growth on Czapek's solution agar; produces the gancidin complex (components A and W) effective against Gram-stain-positive bacteria and tumors; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. pseudogriseolus*, DQ442541, 100%; *S. capillispiralis*, AB184577, 100%; *S. cellulosae*, DQ442495, 99.9%; *S. azureus*, EF178674, 99.5%; *S. levis*, AB184670, 99.4%; *S. lusitanus*, AB184424, 99.4%; *S. rubiginosus*, AY999810, 99.4%; *S. carpinensis*, AB184574, 99.4%; *S. albaduncus*, AY999757, 99.2%; *S. matensis*, AB184221, 99.2%; *S. griseoloalbus*, AB184275, 99.2%; *S. caelestis*, X80824, 99.2%; *S. djakartensis*, AB184657, 99.1%; *S. tuirus*, AB184690, 99.1%; *S. paradoxus*, AB184628, 99.1%; *S. afghaniensis*, AJ399483, 99%; *S. geysiriensis*, DQ442501, 99%; *S. viridiviolaceus*, AY999854, 99%; *S. africanus*, AY208912, 99%; *S. lavendulocolor*, DQ442516, 99%; *S. minutiscleroticus*, EF178696, 99%; *S. spinoverrucosus*, AB184578, 99%; *S. thermocarboxydus*, U94490, 99%; *S. malachitofuscus*, AB184282, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 40935, IFM 1024, NBRC 15412, JCM 4171, NCIMB 12858, NRRL B-1872.

Sequence accession no. (16S rRNA gene): AB184660.

198. **Streptomyces gardneri** (Waksman *in* Waksman, Horning, Welsch and Woodruff 1942) Waksman 1961, 215[AL] ("*Proactinomyces gardneri*" Waksman *in* Waksman, Horning, Welsch and Woodruff 1942, 289; "*Nocardia gardneri*" Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 914)

gard′ne.ri. N.L. gen. masc. n. *gardneri* of Gardner, named for Professor A.D. Gardner, one of the two who first isolated the organism.

Spore chains in Section *Rectiflexibiles*. Spore chains are moderately long, usually 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although aerial mycelium may be poorly developed on oatmeal agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on salts-starch agar in 14–21 d. Mature aerial mycelium may be inadequate for determination of aerial mass color on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. One observer obtained good sporulating aerial growth in the Gray color series on potato agar (potato, 200 g; agar, 10 g; tap water, 1 l; pH 6.9–7.1). Reverse side of colony with no distinctive pigment (colorless to grayish yellow or grayed yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, and potato agar.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar (or only in trace amounts) in 2–4 d. No

pigments are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only traces of growth on iso-inositol and D-mannitol.

Type strain shows no sequence similarity over 99%.

Type strain: ATCC 23911, ATCC 9604, CBS 832.68, BCRC 12346, BCRC 13687, BCRC 13731, DSM 40064, NBRC 12865, NBRC 13974, NBRC 3385, IMET 7182, JCM 3004, JCM 4375, NCTC 6531, NRRL B-5615, NRRL-ISP 5064, RIA 1117, VKM Ac-1829.

Sequence accession no. (16S rRNA gene): AB184757.

199. **Streptomyces gelaticus** (Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 979[AL] ("*Actinomyces gelaticus*" Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923, 356)

ge.la'ti.cus. L. part adj. *gelatus* congealed, jellied; N.L. masc. adj. *gelaticus* intended to mean resembling hardened gelatin.

Spore chains in Section *Rectiflexibiles.* Aerial mycelium is not produced on most media. Absence of aerial mycelium on most media was also noted in the original description (Waksman and Curtis, 1916) which, however, records open spirals on the scant growth on synthetic agar. ISP observers found wavy spore chains, but no spirals in the thin aerial mycelium on yeast-malt agar and glycerol-asparagine agar. The absence of spirals has also been noted by Anderson et al. (1956), by Waksman in a later description (Waksman, 1961), and by Hütter (1967a). Spore surface is smooth.

Color of colony: aerial mycelium is poorly developed on most media. When an adequate spore mass is produced it is in the Gray color series. This was observed on yeast-malt agar and glycerol-asparagine agar. Additional media used unsuccessfully by collaborators in an effort to get good sporulating growth including Bennett's agar, Anderson's agar, blood agar, Lemko agar, and milk agar. Reverse side of colony with no distinctive pigments (colorless to grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, sucrose, D-xylose, and rhamnose are utilized for growth. No growth or only traces of growth on L-arabinose, iso-inositol, D-mannitol, and raffinose.

Type strain shows the highest sequence similarity to: *S. pulveraceus*, AB184806, 99.7%; *S. atratus*, DQ026638, 99.6%; *S. sanglieri*, AB249945, 99.5%; *S. yanii*, AB006159, 99.4%; *S. globisporus* subsp. *globisporus*, EF178686, 99.3%; *S. sindenensis*, AB184759, 99.3%; *S. pluricolorescens*, DQ442540, 99.3%; *S. albovinaceus*, AB249958, 99.3%; *S. flavofuscus*, AB249935, 99.3%; *S. griseinus*, AB184205, 99.3%; *S. fimicarius*, AY999784, 99.3%; *S. anulatus*, DQ026637, 99.3%; *S. mediolani*, AB184674, 99.3%; *S. praecox*, AB184293, 99.3%; *S. badius*, AY999783, 99.3%; *S. rubiginosohelvolus*, AB184240, 99.3%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.2%; *S. californicus*, AB184755, 99.2%; *S. parvus*, DQ442537, 99.2%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.2%; *S. argenteolus*, AB045872, 99.2%; *S. cinereorectus*, AB184646, 99.2%; *S. cyaneofuscatus*, AB184860, 99.2%; *S. griseoplanus*, AY999894, 99.2%; *S. fulvorobeus*, AB184711, 99.1%; *S. acrimycini*, AY999889, 99.1%; *S. microflavus*, DQ445795, 99.1%; *S. griseolus*, AB184768, 99.1%; *S. flavovirens*, DQ026635, 99.1%; *S. halstedii*, EF178695, 99.1%; *S. lipmanii*, AB184148, 99.1%; *S. alboviridis*, AB184256, 99.1%; *S. baarnensis*, EF178688, 99.1%; *S. floridae*, AB184656, 99.1%; *S. griseus* subsp. *griseus*, AY207604, 99.1%; *S. flavogriseus*, AJ494864, 99.1%; *S. luridiscabiei*, AF361784, 99%; *S. nitrosporeus*, EF178680, 99%.

203. **Streptomyces gibsonii** (Erikson 1935) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 963[AL] ["*Actinomyces gibsoni*" (*sic*) Dodge 1935, 722; "*Actinomyces gibsonii*" (*sic*) Erikson 1935, 36; "*Nocardia gibsonii*" Waksman *in* Waksman and Lechevalier 1953, 155]

gib.so′ni.i. N.L. gen. masc. n. *gibsonii* of Gibson, named for A.G. Gibson who first isolated the organism.

Poor growth on Czapek's solution agar; exhibits slight anti-bacterial activity.

Type strain shows the highest sequence similarity to: *S. almquistii*, AB184258, 100%; *S. rangoonensis*, AB184295, 100%; *S. albus* subsp. *albus*, AJ621602, 100%; *S. flocculus*, AB184272, 99.9%.

Source: isolated from a monkey injected with strain NCTC 450 subsequently named *Actinomyces upcottii* Erikson 1935, 36. Originally obtained from the spleen on a case of acholuric jaundice by Dr A.G. Gibson in 1920.

DNA G+C content (mol%): not known.

Type strain: ATCC 6852, CBS 118.60, CBS 119.60, DSM 43284, HUT 6617, NBRC 15415, IMET 7023, JCM 5061, NCTC 4575, NRRL B-1335.

Sequence accession no. (16S rRNA gene): AB184663.

204. **Streptomyces glaucescens** (Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces glaucescesens*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 122)

glau.ces′cens. L. adj. *glaucus* bluish gray; N.L. part. adj. *glaucescens* becoming slightly bluish gray, referring to the bluish green color of the aerial mycelium on a chemically defined medium.

Spore chains in Section *Spirales*. Mature spore chains are short with 3–10 spores per chain. Typical morphology on yeast-malt agar, oatmeal agar, and salts-starch agar, but not typical on glycerol-asparagine agar. Spore surface is hairy. Hairs are coarse, showing some tendency towards spines.

Color of colony: aerial mass color in the Blue or Green color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Color tabs selected by observers fall in both series, but all tabs selected are grayish green. Reverse side of colony is grayed yellow modified by red on yeast-malt agar and glycerol-asparagine agar; modified by green on oatmeal agar and salts-starch agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. pharetrae*, AY699792, 99.3%; *S. matensis*, AB184221, 99.2%; *S. paradoxus*, AB184628, 99.2%; *S. flaveolus*, AB184764, 99.1%; *S. misionensis*, EF178678, 99%; *S. viridochromogenes*, DQ442555, 99%; *S. malachitofuscus*, AB184282, 99%.

Sequence accession no. (16S rRNA gene): AB184843.

205. **Streptomyces glauciniger** Huang, Li, Wang, Lanoot, Vancanneyt, Rodriguez, Liu, Swings and Goodfellow 2004b, 2088[VP]

glau.ci.ni′ger. L. adj. *glaucus* greenish gray; L. adj. *niger* black; N.L. masc. adj. *glauciniger* greenish black, referring to the color of colony reverse on modified Bennett's agar.

Forms an extensively branched substrate mycelium and aerial hyphae that differentiate into long spiral spore

chains with 15–20 cylindrical spores per chain. Spore surface is smooth. Aerial spore mass on oatmeal agar is grayish brown. Soluble pigments are not produced, nor are melanin pigments formed on peptone-yeast extract-iron or tyrosine agars. The organism degrades adenine, casein, hypoxanthine, starch, and xanthine, but not cellulose or elastin. Nitrate is reduced. Gelatin is not liquefied. It uses dextrin, D-galactose, D-glucose (all at 1%, w/v), and sodium acetate, and sodium citrate (both at 0.1%, w/v), but not maltose (1%, w/v), as sole carbon sources for energy and growth. Growth occurs at 10–35°C and pH 5.0–10.0, but not at 40°C or at pH 4.0 or 11.0. Growth also occurs in the presence of phenol (0.1%, w/v) but not in the presence of NaCl (5%, w/v), novobiocin (5 μg/ml), or streptomycin (10 μg/ml). It shows antimicrobial activity against strains of *Bacillus subtilis* and *Candida albicans*, but not against strains of *Aspergillus niger*, *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, or *Staphylococcus aureus*. Cell wall is of type I, phospholipid type II and menaquinone MK-9(H_6, H_8). The fatty acid profile is composed of $C_{16:0}$ iso (25.4%), $C_{17:0}$ anteiso (17.4%), $C_{15:0}$ anteiso (16.7%), $C_{15:0}$ iso (9.5%), $C_{16:0}$ (7.7%), $C_{17:0}$ iso (3.8%), $C_{14:0}$ iso (3.5%), $C_{17:1}$ iso ω9*c* (3.3%), $C_{17:1}$ anteiso ω9*c* (3.0%), $C_{16:1}$ iso (2.9%), $C_{15:0}$ (2.8%), and $C_{17:0}$cyclo (2.7%).

Type strain shows no sequence similarity over 99%.

Source: the type strain was isolated from soil in a willow wood collected in Nanning City, Guangxi Province, China.

DNA G+C content (mol%): 67.0.

Type strain: FXJ14, AS 4.1858, JCM 12278, LMG 22082, NBRC 100913.

Sequence accession no. (16S rRNA gene): AB249964.

206. **Streptomyces glaucosporus** (*ex* Krasil'nikov, Agre, Dorokhova and Sokolov 1968) Agre 1986, 574[VP] (Effective publication: Agre *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces glaucosporus*" Krasil'nikov, Agre, Dorokhova and Sokolov 1968)

glau.co.spo′rus. L. adj. *glaucus* bluish gray; N.L. n. *spora* a spore; N.L. masc. adj. *glaucosporus* bluish gray spored.

Spore chains are spiral (*Spirales*); spores are warty. On mineral agar 1, oatmeal agar: aerial mycelium poorly or well developed, green-gray; substrate mycelium is dark yellow; no diffusible pigment. On starch-ammonia agar: aerial mycelium is green-gray; substrate mycelium is yellowish; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is poorly developed, green-gray; substrate mycelium is colorless; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium poorly developed, gray; substrate mycelium is colorless; no diffusible pigment. On organic agar 2: aerial mycelium is green-gray; substrate mycelium and diffusible pigment are dark yellow, brown-yellow. Melanoid pigments are not formed. Good utilization of glucose, maltose, and xylose; weak utilization of sucrose, rhamnose, and inositol.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25183, DSM 41689, NBRC 15416, INMI 2979, INA G-72, JCM 6921, VKM Ac-1763.

Sequence accession no. (16S rRNA gene): AB184664.

207. **Streptomyces glaucus** (*ex* Lehmann and Schütze 1912) Agre and Preobrazhenskaya 1986, 574[VP] (Effective publication: Agre and Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces glaucus*" Lehmann and Schütze 1912; "*Streptomyces glaucus*" Waksman 1953)

glau′cus. L. masc. adj. *glaucus* bluish gray.

Spore chains are spiral (*Spirales*); spore surface is hairy and rough. On mineral agar 1 and oatmeal agar: aerial mycelium mealy, greenish-bluish; substrate mycelium and diffusible pigment are brown. On glycerol-nitrate agar: aerial mycelium poorly developed, white; substrate mycelium dark brown; diffusible pigment brown. On starch-ammonia agar: aerial mycelium is bluish-greenish; substrate mycelium colorless; diffusible pigment brown. On glycerol-asparagine agar: aerial mycelium is bluish; substrate mycelium is colorless to brownish; diffusible pigment is brownish or absent. On organic agar 2: aerial mycelium poorly developed, white; substrate mycelium dark grayish brown. Melanoid pigments are not formed. Good growth on starch, glucose, lactose, xylose, maltose, rhamnose, glycerol, and mannitol; moderate growth on arabinose and laevulose; poor growth on galactose and inositol; no growth on dulcitol, sorbitol, or sucrose. Cultures belonging to this species are produce antibiotic RA 166 (PA 166-russ).

Type strain shows the highest sequence similarity to: *S. griseomycini*, AB184137, 99.1%; *S. gramineárus* AJ781333, 99.1%; *S. griseostramineus*, AB184140, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 43685, DSM 41456, NBRC 15417, INMI 2965, INA G-86, JCM 6922, NRRL B-16368, VKM Ac-803.

Sequence accession no. (16S rRNA gene): AB184665.

208a. **Streptomyces globisporus subsp. globisporus** (Krasil'nikov 1941) Waksman *in* Waksman and Lechevalier 1953, 39[AL] ("*Actinomyces globisporus*" Krasil'nikov 1941, 48)

glo.bi.spo′rus. L. n. *globus* a round body; N.L. n. *spora* a spore; N.L. masc. adj. *globisporus* round spored (as determined by light microscopy).

Spore chains in Section *Rectiflexibiles*. Mature spore chains are predominantly flexuous and moderately long with 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale yellow to light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow to greenish yellow pigment may be found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not sensitive when tested with 0.05 M HCl or NaOH.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. sindenensis*, AB184759, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. griseinus*, AB184205, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. praecox*, AB184293, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. albovinaceus*, AB249958, 99.9%; *S. anulatus*, DQ026637, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. californicus*, AB184755, 99.8%; *S. fulvorobeus*, AB184711, 99.8%; *S. parvus*, DQ442537, 99.8%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.8%; *S. argenteolus*, AB045872, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. lipmanii*, AB184148, 99.7%; *S. microflavus*, DQ445795, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. floridae*, AB184656, 99.7%; *S. bacillaris*, AB184439, 99.7%; *S. cinereorectus*, AB184646, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. griseolus*, AB184768, 99.6%; *S. flavovirens*, DQ026635, 99.6%; *S. albolongus*, AB184425, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. halstedii*, EF178695, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. atroolivaceus*, AJ781320, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. yanii*, AB006159, 99.4%; *S. finlayi*, AY999788, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. flavogriseus*, AJ494864, 99.4%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. griseus* subsp. *griseus*, AY207604, 99.3%; *S. luridiscabiei*, AF361784, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. gelaticus*, DQ026636, 99.3%; *S. mutomycini*, AB249951, 99.1%; *S. candidus*, DQ026663, 99.1%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cremeus*, AB184124, 99%.

Sequence accession no. (16S rRNA gene): AJ781330.

210. **Streptomyces glomeratus** (*ex* Gause and Sveshnikova 1978) Gause and Preobrazhenskaya 1986a, 574^VP^ (Effective publication: Gause and Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Streptomyces glomeratus*" Gause and Sveshnikova *in* Gause et al. 1978)

glo.me.ra′tus. L. masc. part. adj. *glomeratus*, formed into a ball, conglobated, glomerated.

Spore chains are hooks, loops, or spiral with 1 or 2 turns; spores look like quasi-sporangia. Spores are smooth. On mineral agar 1: aerial mycelium is whitish gray, light gray to greenish gray; substrate mycelium is grayish blue to grayish brown-blue; diffusible pigment is absent or sometimes pale reddish violet colored. On starch-ammonia agar: aerial mycelium is white to gray brownish gray, greenish gray; substrate mycelium is colorless to gray brown and grayish brown-blue; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium poorly developed, whitish, sometimes greenish gray; substrate mycelium is gray brownish; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is white to gray brownish gray, sometimes with greenish shadow; substrate mycelium is grayish gray-brown, violet gray-brown; no diffusible pigment. On glucose-asparagine agar: aerial mycelium is grayish white, light greenish gray; substrate mycelium is colorless to brown and grayish brown-blue; no diffusible pigment. Oatmeal agar: aerial mycelium is gray-green; substrate mycelium is gray-brown, gray- brown-blue, gray- blue, sometimes with olive shadow; no diffusible pigment. On organic agar: aerial mycelium is grayish green, sometimes absent; substrate mycelium is grayish gray-brown; diffusible pigment is gray brown. Melanoid pigment is formed. Antibiotic: beromycin, nogalamycin (indicator pigment changing color from yellow in acidic medium to red-violet in alkaline medium). Moderate growth on xylose, rhamnose, fructose, and mannitol; poor growth on arabinose, raffinose, and sucrose; no growth on cellulose.

Type strain shows the highest sequence similarity to: *S. bangladeshensis*, AY750056, 99.2%; *S. rameus*, AY999821, 99.1%; *S. achromogenes* subsp. *rubradiris*, AY999846, 99%.

DNA G+C content (mol%): not known.

Type strain: DSM 41457, NBRC 15898, INA 3980, JCM 9091, VKM Ac-834.

Sequence accession no. (16S rRNA gene): AB249917.

211. **Streptomyces glomeroaurantiacus** (Krasil'nikov and Yuan *in* Krasil'nikov 1965) Pridham 1970, 17[AL] ("*Actinomyces glomeroaurantiacus*" Krasil'nikov and Yuan *in* Krasil'nikov 1965, 50)

glo.me.ro.au.ran.ti′a.cus. L. v. *glomero* form into a ball; N.L. adj. *aurantiacus* orange colored; N.L. masc. adj. *glomeroaurantiacus* (*sic*) orange-colored ball.

Spore chains in Section *Spirales*, but aerial mycelium is poorly developed and typical spore chains are difficult to find on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Mature spore chains on these media are generally very short or absent. Spore surface: Smooth. Conidia-like spores or fragmentation of the substrate mycelium may be seen on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

Color of colony: growth of aerial mycelium is not adequate for determination of aerial mass color on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Reverse side of colony is yellowish pink, orange or reddish orange on yeast-malt agar and glycerol-asparagine agar; no distinctive pigments (grayish yellow, orange yellow or yellowish brown) on oatmeal agar or salts-starch agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. One of three observers records orange to pink or red pigment in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary from doubtful growth to positive growth with D-xylose, iso-inositol, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. aurantiacus*, AJ781383, 100%; *S. tauricus*, AB045879, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 15866, DSM 41782, JCM 4677, NBRC 15418, INMI 1464, NRRL B-3375, RIA 683.

Sequence accession no. (16S rRNA gene): AB249983.

212. **Streptomyces gobitricini** (Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces gobitricini*" Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 34)

go.bi.tri.ci′ni. English n. *Gobi* the Gobi Desert in Mongolia; Gr. n. *thrix* the hair; N.L. *gobitricini* (*sic*) of gobi hair, referring to the Gobi desert, the first source of the soil from which the organism was isolated, and probably to formation of a streptothricin-like antibiotic.

Some spore chains are of atypical *Retinaculum-Apertum* type; moderate growth on Czapek's solution agar. Exhibits anti-bacterial and anti-fungal activity; inhibited by streptomycin; NaCl tolerance >7%, but <10%.

Type strain shows the highest sequence similarity to: *S. lavendofoliae*, AJ781336, 99.8%; *S. luridus*, DQ442523, 99.5%.

Source: isolated from soil from the Gobi desert.

DNA G+C content (mol%): not known.

Type strain: CBS 123.60, DSM 41701, NBRC 15419, JCM 5062, NRRL B-2596.

Sequence accession no. (16S rRNA gene): AB184666.

213. **Streptomyces goshikiensis** Niida *in* Shirling and Gottlieb 1966, 324[AL]

gos.hi.ki.en′sis. etymology unknown.

Spore chains in Section *Spirales*, with open spirals of 4–10 convolutions at the end of long spore chains. Mature spore chains have 10–50 spores per chain; longer chains are often observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth with minor surface irregularities, but no true spines.

Color of colony: aerial mass color in the Red (or Gray) color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Characteristic color on these media in between 3ge (light grayish yellowish brown) and 5dc or 6ec (grayish yellowish pink) color tabs of Tresner–Backus

Color Wheels. Aerial mycelium may be poorly developed on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (characteristic grayed yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar to light orange yellow or light brown on yeast-malt agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids or faint traces of yellow are not produced in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and possibly D-fructose are utilized for growth. Only traces of growth comparable to growth on carbon-free basal medium seen on L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. colombiensis*, DQ026646, 100%; *S. sporoverrucosus*, DQ442544, 100%; *S. nojiriensis*, AJ781355, 99.9%; *S. spororaveus*, AJ781370, 99.9%; *S. xanthophaeus*, DQ442560, 99.8%; *S. vinaceus*, AB184394, 99.7%; *S. cirratus*, AY999794, 99.7%; *S. cinnamonensis*, AB184707, 99.6%; *S. avidinii*, AB184395, 99.6%; *S. subrutilus*, X80825, 99.5%; *S. virginiae*, D85119, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23914, CBS 835.68, BCRC 12330, CCUG 11121, DSM 40190, NBRC 12868, IMET 42067, JCM 4294, JCM 4640, NCIMB 9828, NRRL B-5428, NRRL-ISP 5190, RIA 1144, VKM Ac-1212.

Sequence accession no. (16S rRNA gene): EF178693.

214. **Streptomyces gougerotii** (Duché 1934) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 947[AL] [“*Actinomyces gougeroti*” (*sic*) Duché 1934, 272; “*Streptomyces gougerotii*” Waksman and Henrici *in* Hütter 1967b, 75]

gou.ge.ro′ti.i. N.L. gen. masc. n. *gougerotii* of Gougerot; named for Professor Gougerot from whom the original culture was obtained.

Spore chains in Section *Rectiflexibiles* on yeast-malt agar; aerial mycelium is very thin on this medium and is usually not produced on oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Spore chains, when produced, are moderately short with 3 to 10 or more spores per chain. Two observers recorded fragmentation of the substrate mycelium and this characteristic is also mentioned in Duché’s original description (op. cit). Spore surface is smooth.

Color of colony: aerial mass color in the White or Yellow (2ba, pale yellow) color series on yeast-malt agar. Aerial mycelium is usually thin on yeast-malt agar and is often inadequate for color observation on all other ISP media. Reverse side of colony with no distinctive pigments (colorless to grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in tyrosine agar or tryptone-yeast broth; reports vary on production of dark pigment in peptone-yeast-iron agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Reports vary on utilization of L-arabinose, iso-inositol, and rhamnose. No growth or only traces of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. diastaticus* subsp. *diastaticus*, AB184785, 100%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 100%; *S. intermedius*, AB184277, 99.8%; *S. misionensis*, EF178678, 99.2%; *S. phaeoluteichromatogenes*, AJ391814, 99.1%%; *S. matensis*, AB184221, 99%%; *S. aureoverticillatus*, AY999774, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 10975, ATCC 25455, CBS 422.34, CBS 688.69, BCRC 12105, DSM 40324, NBRC 13043, NBRC 3198, IMET 40289, JCM 4136, JCM 4478, NRRL B-1344, NRRL B-1903, NRRL-ISP 5324, RIA 1235, VKM Ac-713.

Sequence accession no. (16S rRNA gene): AB184742.

215. **Streptomyces graminearus** Preobrazhenskaya 1986, 574[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

gra.mi.ne.a′rus. N.L. masc. adj. *graminearus* related to grain, isolated from grain.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: aerial mycelium is gray or green-gray; substrate mycelium is light yellow; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is poor, white; substrate mycelium is yellow, citreous; no diffusible pigment. On oatmeal agar: aerial mycelium is gray; substrate mycelium is colorless or light citreous; no diffusible pigment. On starch-ammonia agar: aerial mycelium is grayish gray; substrate mycelium is yellow; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is poor, white; substrate mycelium is yellow; no diffusible pigment. On organic agar 2: aerial mycelium is white; substrate mycelium is colorless or yellow; no diffusible pigment. Melanoid pigments are not formed. Grows on glucose, fructose, starch, mannitol, sucrose, and arabinose; weak growth on raffinose, rhamnose, and inositol.

Type strain shows the highest sequence similarity to: *S. griseostramineus*, AB184140, 100%; *S. griseomycini*, AB184137, 100%; *S. glaucus*, AB184665, 99.1%; *S. calvus*, AB184329, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 41474, NBRC 15420, INA 13982, JCM 6923, NRRL B-16369, VKM Ac-1847.

Sequence accession no. (16S rRNA gene): AJ781333.

216. **Streptomyces graminofaciens** Charney, Fisher, Curran, Machlowitz and Tytell 1953, 1283[AL]

gra.mi.no.fa′ci.ens. L. n. *gramen* grass; L. part. adj. *faciens* producing; N.L. part. adj. *graminofaciens* grass producing, probably refers to production of (strepto)gramin.

Spore chains in Section *Spirales*. Open spirals of four or more turns, irregular spirals and hooks, or tight terminal spirals may be found on various media. Mature spore chains are generally long, sometimes with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is warty.

Color of colony: aerial mass color in the Gray or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Only one of three observers records aerial mycelium in the Red color series (5dc, grayish yellowish pink) on yeast-malt agar in 21 d. Nearest matching color tabs in the Gray color series are d, light gray; 2dc, yellow gray; and 5fe, light grayish reddish brown. Reverse side of colony with no distinctive pigments (grayish yellow to brown on yeast-malt agar; pale grayish or greenish yellow to light yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. kurssanovii*, AB184325, 100%; *S. xantholiticus*, AB184349, 99.8%; *S. peucetius*, AB045887, 99.7%; *S. cremeus*, AB184124, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 12705, CBS 756.72, BCRC 12352, CECT 3217, DSM 40559, HAMBI 982, NBRC 13455, IMET 43540, JCM 4157, JCM 4762, NRRL B-2609, NRRL-ISP 5559, RIA 1416, VKM Ac-973.

Sequence accession no. (16S rRNA gene): AJ781329.

217. **Streptomyces griseiniger** Goodfellow, Kumar, Labeda and Sembiring 2008, 1[VP] (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 198.)

gri.se.i.ni′ger. N.L. adj. *griseus* gray; L. adj. *niger* black; N.L. masc. adj. *griseiniger* gray-black.

Spore chains are *Spriales*; spore surface is rugose. On oatmeal agar, the aerial spore mass color is gray, becoming black and moist when mature; the reverse side of colonial growth is grayish-yellow. Melanin pigments are not formed.

Type strain shows the highest sequence similarity to: *S. rhizosphaericus*, AB249941, 99.8%; *S. asiaticus*, AB249947, 99.8%; *S. cangkringensis*, AJ391831, 99.5%; *S. indonesiensis*, DQ334783, 99.4%. Type strain shows DNA–DNA similarity to: *S. cangkringensis* DSM 41769^T, 59%; *S. hygroscopicus* subsp. *geldanus* NRRL 3602^T, 56%; *S. indonesiensis* DSM 41759^T, 62%; *S. melanosporofaciens* NRRL B-12234^T, 57%.

Source: not known.

DNA G+C content (mol%): 70.2.

Type strain: DSM 41895, NRRL B-1865.

Sequence accession no. (16S rRNA gene): AJ391818.

218. **Streptomyces griseinus** Waksman 1959, 1045[AL]

gri.se.i′nus.N.L. n. *griseinum* grisein, name of an antibiotic; L. masc. suff. *-inus* suffix used with the sense of belonging to; N.L. masc. adj. *griseinus* belonging to grisein, the antibiotic produced by the organism.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are predominantly flexuous and moderately long with 10–50, or often more than 50, spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on salts-starch agar and glycerol-asparagine agar and in the Yellow or Gray color series on oatmeal agar and yeast-malt agar. Nearest matching color tab from the Gray color series is 2dc, yellowish gray. Reverse side of colony: no distinctive pigments (grayish yellow to yellowish brown or light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. The substrate mycelium pigment may be changed slightly from pale yellow to pale yellow-brown or pale violet with addition of 0.05 M NaOH, or from yellowish brown to pale yellow with 0.05 M HCl.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. A trace of yellow to reddish brown pigment may be found in the medium in oatmeal agar. This pigment, when present, is slightly pH-sensitive changing from pale yellow to pale violet with addition of 0.05 M NaOH.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. sindenensis*, AB184759, 100%; *S. albovinaceus*, AB249958, 100%; *S. griseoplanus*, AY999894, 100%; *S. anulatus*, DQ026637, 100%; *S. globisporus* subsp. *globisporus*, EF178686, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. praecox*, AB184293, 100%; *S. flavofuscus*, AB249935, 100%; *S. fimicarius*, AY999784, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. californicus*, AB184755, 99.9%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.9%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.9%; *S. acrimycini*, AY999889, 99.9%; *S. parvus*, DQ442537, 99.9%; *S. fulvorobeus*, AB184711, 99.8%; *S. lipmanii*, AB184148, 99.8%; *S. microflavus*, DQ445795, 99.8%; *S. cyaneofuscatus*, AB184860, 99.8%; *S. floridae*, AB184656, 99.8%; *S. alboviridis*, AB184256, 99.8%; *S. baarnensis*, EF178688, 99.8%; *S. cinereorectus*, AB184646, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. bacillaris*, AB184439, 99.6%; *S. pulveraceus*, AB184806, 99.6%; *S. halstedii*, EF178695, 99.6%; *S. flavogriseus*, AJ494864, 99.6%; *S. atroolivaceus*, AJ781320, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. albolongus*, AB184425, 99.4%; *S. clavifer*, DQ026670, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. sanglieri*, AB249945, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. yanii*, AB006159, 99.4%; *S. gelaticus*, DQ026636, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. mutomycini*, AB249951, 99.2%; *S. candidus*, DQ026663, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cremeus*, AB184124, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23915, CBS 836.68, BCRC 11480, CCUG 11106, DSM 40047, NBRC 12869, JCM 4379, NRRL B-1076, NRRL-ISP 5047, RIA 1113.

Sequence accession no. (16S rRNA gene): AB184205.

219. **Streptomyces griseoaurantiacus** (Krasil'nikov and Yuan *in* Krasil'nikov 1965) Pridham 1970, 17[AL] ("*Actinomyces griseoaurantiacus*" Krasil'nikov and Yuan *in* Krasil'nikov 1965, 52)

gri.se.o.au.ran.ti.a′cus N.L. adj. *griseus* gray; N.L. adj. *aurantiacus* orange colored; N.L. masc. adj. *griseoaurantiacus* orange colored with gray.

Spore chains in Section *Spirales*. Hooks, loops, and primitive spirals suggesting *Retinaculiaperti* morphology are very common. Mature spore chains have 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray; 2fe, medium gray; 3fe, light brownish gray; or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar and salts-starch agar. Gray or Red color series (5dc, grayish yellowish pink) on glycerol-asparagine agar. Reverse side of colony is grayish yellow to orange yellow, yellowish pink, or dark reddish orange on yeast-malt agar; yellowish pink or reddish gray to reddish orange on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar is a pH indicator, changing from orange to red with the addition of 0.05 M HCl and from orange to brown with the addition of 0.05 M NaOH.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow orange or pinkish red may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 21 d. This pigment, when formed in sufficient quantity, is pH-sensitive, showing the same changes observed for reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of raffinose is doubtful. No growth or only traces of growth with sucrose.

Type strain shows the highest sequence similarity to: *S. jietaisiensis*, AY314783, 99.7%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB184676.

220. **Streptomyces griseobrunneus** Waksman 1961, 220[AL]

gri.se.o.brun′ne.us. N.L. adj. *griseus* gray; N.L. adj. *brunneus* dark brown; N.L. masc. adj. *griseobrunneus* grayish dark-brown colored.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Special morphological characteristics: substrate conidia noted by two observers.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Pigments other than melanoid not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on L-arabinose, sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. celluloflavus*, AB184476, 100%; *S. albolongus*, AB184425, 100%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.9%; *S. californicus*, AB184755, 99.5%; *S. bacillaris*, AB184439, 99.4%; *S. floridae*, AB184656, 99.4%; *S. globisporus* subsp. *globisporus*, EF178686, 99.4%; *S. griseinus*, AB184205, 99.4%; *S. fulvorobeus*, AB184711, 99.4%; *S. pluricolorescens*, DQ442540, 99.4%; *S. candidus*, DQ026663, 99.4%; *S. spiroverticillatus*, AB184814, 99.4%; *S. sindenensis*, AB184759, 99.4%; *S. badius*, AY999783, 99.4%; *S. rubiginosohelvolus*, AB184240, 99.4%; *S. mediolani*, AB184674, 99.4%; *S. praecox*, AB184293, 99.3%; *S. albovinaceus*, AB249958, 99.3%; *S. microflavus*, DQ445795, 99.3%; *S. fimicarius*, AY999784, 99.3%; *S. flavofuscus*, AB249935, 99.5%; *S. alboviridis*, AB184256, 99.3%; *S. lipmanii*, AB184148, 99.3%; *S. cremeus*, AB184124, 99.3%; *S. griseoplanus*, AY999894, 99.3%; *S. anulatus*, DQ026637, 99.3%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.2%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.2%; *S. parvus*, DQ442537, 99.2%; *S. luridiscabiei*, AF361784, 99.2%; *S. acrimycini*, AY999889, 99.2%; *S. baarnensis*, EF178688, 99.2%; *S. cyaneofuscatus*, AB184860, 99.2%; *S. cinereorectus*, AB184646, 99.2%; *S. flavovirens*, DQ026635, 99.2%; *S. argenteolus*, AB045872, 99.1%; *S. finlayi*, AY999788, 99.1%; *S. flavogriseus*, AJ494864, 99.1%; *S. nitrosporeus*, EF178680, 99%; *S. griseolus*, AB184768, 99%; *S. pulveraceus*, AB184806, 99%; *S. clavifer*, DQ026670, 99%; *S. griseus* subsp. *griseus*, AY207604, 99%; *S. halstedii*, EF178695, 99%; *S. cinnamonensis*, AB184707, 99%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB249912.

221. **Streptomyces griseocarneus** (Benedict, Lindenfelser, Stodola and Traufler 1950) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Streptomyces griseocarneus*" Benedict, Lindenfelser, Stodola and Traufler 1950; "*Streptoverticillium griseocarneus*" (*sic*) Baldacci 1958; "*Verticillomyces griseocarneus*" Shinobu 1965; *Streptoverticillium griseocarneum* Baldacci, Farina and Locci 1966, 170]

gri.se.o.car′ne.us. L. adj. *griseus* gray; L. adj. *carneus* pertaining to flesh; N.L. masc. adj. *griseocarneus* gray flesh-colored.

Spore chains in Umbellate monoverticillate (=*Streptomyces* Section *Verticillati*, biverticillate). Mature spore chains are short, generally 3–10 spores per chain. This morphology is seen on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Mature spores often not produced until 14–21 d. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; good spore mass not produced on oatmeal agar. Reverse side of colony with no distinctive pigments (grayed yellow to yellow-brown) on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose is utilized for growth. No growth or only traces of growth on sucrose, rhamnose, and raffinose. Variable reports on growth with L-arabinose, D-xylose, iso-inositol, D-mannitol, and D-fructose (but if growth occurs with these carbon sources it is less than with D-glucose).

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1088, ATCC 12628, ATCC 19763, CBS 501.68, CCM 3228, BCRC 13304, CCUG 11123, CECT 3250, DSM 40004, NBRC 12776, NBRC 3387, JCM 4095, JCM 4580, LMG 5973, NCIMB 9623, NRRL B-1068, NRRL B-1350, NRRL-ISP 5004, PCM 2326, PCM 2345, RIA 1043, RIA 132, UNIQEM 149, VKM Ac-881.

Sequence accession no. (16S rRNA gene): X99943.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces griseocarneus* is proposed as a *nomen revictum* (basonym: "*Streptomyces griseocarneus*" Benedict et al. (1950).

According to Hatano et al. (2003), *Streptomyces griseocarneus* (Benedict et al. 1950) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces alboverticillatus* (Locci and Schofield 1989) Witt and Stackebrandt 1991 and of *Streptomyces septatus* (Locci et al. 1969) Witt and Stackebrandt 1991. Hatano et al. (2003) also propose that *Streptomyces griseocarneus* (Benedict et al. 1950) Witt and Stackebrandt 1991 be a heterotypic synonym of "*Streptomyces tropicalensis*" Gupta 1965b.

222. **Streptomyces griseochromogenes** Fukunaga *in* Fukunaga, Misato, Ishii and Asakawa 1955, 181[AL]

gri.se.o.chro.mo′ge.nes. N.L. adj. *griseus* gray; Gr. n. *chroma* color; N.L. suff. -*genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *griseochromogenes* producing gray color.

Spore chains in Section *Spirales* to *Retinaculiaperti*. Open loops and hooks as well as well-developed spirals are common. Mature spore chains generally contain 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series (2fe, medium gray, or 3ge, light grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; white aerial mycelium may also be seen on young cultures or on 21-d-old cultures on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow to orange yellow on yeast-malt agar; grayish yellow to light olive brown or grayish greenish yellow on oatmeal agar, salts-starch agar, or glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, sucrose, and raffinose are utilized for growth. No growth or only traces of growth with rhamnose.

Type strain shows the highest sequence similarity to: *S. cellostaticus*, AB184192, 99.7%; *S. yokosukanensis*, DQ026652, 99.3%; *S. corchorusii*, AB184267, 99%; *S. olivaceoviridis*, AB184288, 99%.

223. **Streptomyces griseoflavus** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 948[AL] ("*Actinomyces griseoflavus*" Krainsky 1914, 694)

gri.se.o.fla′vus. N.L. adj. *griseus* gray; L. adj. *flavus* yellow; N.L. masc. adj. *griseoflavus* grayish yellow.

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50 spores per chain, although shorter chains may also be common. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (immature cultures may appear to be in the Yellow color series on glycerol-asparagine agar). Reverse side of colony is yellow to orange-yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. griseorubens*, AB184139, 99.7%; *S. griseoincarnatus*, AJ781328, 99.6%; *S. erythrogriseus*, AJ781328, 99.6%; *S. labedae*, AB184704, 99.6%; *S. variabilis*, DQ442551, 99.6%; *S. flaveolus*, AB184764, 99.5%; *S. collinus*, AB184123, 99.5%;

224. **Streptomyces griseofuscus** Sakamoto, Kondo, Yumoto and Arishima 1962, 98[AL]

gri.se.o.fus′cus. N.L. adj. *griseus* gray; L. adj. *fuscus* dark, tawny; N.L. masc. adj. *griseofuscus* gray, tawny.

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red or Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Characteristic color is between 4ge or 5ge (light grayish reddish brown) and 4ig (light grayish brown) color tabs of Tresner–Backus color wheels. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. murinus*, AB184155, 100%; *S. costaricanus*, AB249939, 100%; *S. phaeogriseichromatogenes*, AJ391813, 99.6%.

Type strain: ATCC 23916, CBS 837.68, BCRC 10483, CECT 3307, DSM 40191, NBRC 12870, IMET 42068, JCM 4276, JCM 4641, NCIMB 9821, NRRL B-5429, NRRL-ISP 5191, RIA 1145, VKM Ac-1707.

Sequence accession no. (16S rRNA gene): AB184206.

225. **Streptomyces griseoincarnatus** (Preobrazhenskaya, Ryabova and Blinov *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 69[AL] ("*Actinomyces griseoincarnatus*" Preobrazhenskaya, Ryabova and Blinov *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 169)

gri.se.o.in.car.na′tus. N.L. adj. *griseus* gray; L. part. adj. *incarnatus* flesh-colored; N.L. masc. part. adj. *griseoincarnatus* grayish flesh-colored, referring to changes in color of the aerial mycelium.

Spore chains in Section *Spirales*. Spirals are generally open with 3 to 7 or more turns; flexuous spore chains and imperfect spirals suggesting *Retinaculiaperti* morphology are also common. Spirals are best developed on oatmeal agar and salts-starch agar. Spore chains are moderately long, especially on oatmeal agar and salts-starch agar with 10–50, or often more than 50, spores per chain. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on salts-starch agar ater 14–21 d; younger aerial mycelium may be in the Red color series. Aerial mass color in the Gray or Red color series yeast-malt agar, oatmeal agar, and salts-starch agar. Observers did not agree on the selection of individual color tabs representing the aerial color, but all chose tabs ranging form grayish yellowish pink or grayish reddish brown to medium gray. Reverse side of colony is yellow to yellow brown plus red (grayish yellow on salts-starch agar; orange-yellow to reddish brown on yeast-malt agar, oatmeal agar). Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red or orange pigment is found in the medium in yeast-malt agar in 7 d and in oatmeal agar in 14–21 d. Red or orange pigment may or may not be found in glycerol-asparagine agar. This pigment is not a pH indicator.

D-Glucose, L-arabinose, sucrose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on utilization of iso-inositol and only traces of growth are found on raffinose.

Type strain shows the highest sequence similarity to: *S. erythrogriseus*, AJ781328, 100%; *S. labedae*, AB184704, 100%; *S. variabilis*, DQ442551, 100%; *S. griseorubens*, AB184139, 99.9%; *S. griseoflavus*, AJ781322, 99.6%; *S. matensis*, AB184221, 99.6%; *S. althioticus*, AY999808, 99.2%; *S. paradoxus*, AB184628, 99.2%; *S. heliomycini*, AB184712, 99.1%; *S. collinus*, AB184123, 99.1%; *S. viridochromogenes*, DQ442555, 99.1%; *S. flaveolus*, AB184764, 99.1%; *S. bellus*, AB184849, 99%; *S. albogriseolus*, AJ494865, 99%; *S. viridodiastaticus*, AY999852, 99%; *S. violaceochromogenes*, AY999867, 99%; *S. malachitofuscus*, AB184282, 99%; *S. violaceorubidus*, AJ781374, 99%; *S. coerulescens*, AY999720, 99%.

Type strain: AS 4.1409, ATCC 23623, ATCC 23917, CBS 838.68, BCRC 11481, DSM 40274, NBRC 12871, INA 9673/55, JCM 4381, LMG 19316, NCIMB 9825, NRRL B-5313, NRRL-ISP 5274, RIA 1192.

Sequence accession no. (16S rRNA gene): AJ781321.

226. **Streptomyces griseoloalbus** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 58[AL] ("*Actinomyces griseoloalbus*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 112)

gri.se.o.lo.al′bus. N.L. dim. adj. *griseolus* somewhat gray; L. adj. *albus* white; N.L. masc. adj. *griseoloalbus* somewhat grayish white.

Spore chain in Section *Rectiflexibiles*. Aerial hyphae may be sterile or spores may be poorly defined. Spore surface is smooth. Terminal swellings of two types are sometimes seen on aerial hyphae. Aerial mycelium is best developed on yeast-malt agar and salts-starch agar, but good sporulating aerial mycelium is not found on any of the ISP media. In addition to the terminal swellings noted above, one observer records fragmentation of the substrate mycelium on yeast-malt agar and salts-starch agar.

Color of colony: aerial mass color in the White or Yellow (2ba, pale yellow) color series on yeast-malt agar and salts-starch agar; a white aerial mycelium may or may not be formed on oatmeal agar and glycerol-asparagine agar, but this mycelium is usually sterile. Reverse side of colony is light yellow or grayish yellow to orange-yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. A trace of yellow to orange-yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar or glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and sucrose are utilized for growth. Reports vary on the utilization of raffinose.

Type strain shows the highest sequence similarity to: *S. albaduncus*, AY999757, 100%; *S. matensis*, AB184221, 99.2%; *S. gancidicus*, AB184660, 99.2%; *S. paradoxus*, AB184628, 99.%; *S. pseudogriseolus*, DQ442541, 99.1%; *S. capillispiralis*, AB184577, 99%; *S. heliomycini*, AB184712, 99%; *S. malachitofuscus*, AB184282, 99%; *S. cellulosae*, DQ442495, 99%; *S. lusitanus*, AB184424, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23624, ATCC 25458, CBS 691.69, DSM 40468, NBRC 13046, INA 1875/54, JCM 4480, NRRL B-12383, NRRL-ISP 5468, RIA 1238, VKM Ac-1739.

Sequence accession no. (16S rRNA gene): AB184275.

227. **Streptomyces griseolus** (Waksman 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 938[AL] ("*Actinomyces griseolus*" Waksman *in* Bergey, Harrison, Breed, Hammer and Huntoon 1923, 369)

gri.se′o.lus. N.L. adj. *griseus* gray; N.L. dim. masc. adj. *griseolus* somewhat gray.

Spore chain in Section *Rectiflexibiles*. Mature spore chains are moderately short with 3–10, or sometimes more than 10, spores per chain (one observer reports 10–50 spores per chain). This morphology is seen on yeast-malt agar; sporulation on oatmeal agar, salts-starch agar, or glycerol-asparagine agar may be poor. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar; sporulation usually inadequate for color determination on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is yellow-brown to brown on yeast-malt agar and colorless or characteristic grayed yellow to grayed yellow-brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and D-fructose are utilized for growth. No growth or only traces of growth with iso-inositol and raffinose. Variable reports on growth with sucrose, D-mannitol, and rhamnose; interpretation is difficult because of significant growth on the carbon-free basal medium.

Type strain shows the highest sequence similarity to: *S. halstedii*, EF178695, 100%; *S. cinereorectus*, AB184646, 99.9%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.8%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. mediolani*, AB184674, 99.7%; *S. pluricolorescens*, DQ442540, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. flavofuscus*, AB249935, 99.7%; *S. sindenensis*, AB184759, 99.7%; *S. lipmanii*, AB184148, 99.7%; *S. praecox*, AB184293, 99.7%; *S. microflavus*, DQ445795, 99.7%; *S. griseinus*, AB184205, 99.7%; *S. rubiginosohelvolus*, AB184240, 99.7%; *S. anulatus*, DQ026637, 99.7%; *S. fimicarius*, AY999784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. badius*, AY999783, 99.7%; *S. fulvorobeus*, AB184711, 99.7%; *S. flavogriseus*, AJ494864, 99.7%; *S. griseoplanus*, AY999894, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. baarnensis*, EF178688, 99.6%; *S. acrimycini*, AY999889, 99.6%; *S. globisporus* subsp. *globisporus*, EF178686, 99.6%; *S. floridae*, AB184656, 99.6%; *S. griseus* subsp. *griseus*, AY207604, 99.6%; *S. albovinaceus*, AB249958, 99.6%; *S. luridiscabiei*, AF361784, 99.6%; *S. parvus*, DQ442537, 99.5%; *S. californicus*, AB184755, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. pulveraceus*, AB184806, 99.4%; *S. yanii*, AB006159, 99.4%; *S. olivoviridis*, AB184227, 99.3%; *S. finlayi*, AY999788, 99.3%; *S. atroolivaceus*, AJ781320, 99.3%; *S. bacillaris*, AB184439, 99.2%; *S. sanglieri*, AB249945, 99.2%; *S. clavifer*, DQ026670, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. albolongus*, AB184425, 99.1%; *S. gelaticus*, DQ026636, 99.1%; *S. atratus*, DQ026638, 99.1%; *S. celluloflavus*, AB184476, 99%; *S. cremeus*, AB184124, 99%; *S. mutomycini*, AB249951, 99%; *S. griseobrunneus*, AB249912, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19764, ATCC 3325, CBS 502.68, BCRC 13677, DSM 40067, HAMBI 1000, HUT 6056, HUT 6099, NBRC 12777, NBRC 3415, NBRC 3719, IMET 42053, JCM 4042, JCM 4043, JCM 4581, KCTC 9028, NCIMB 9606, NRRL B-1062, NRRL B-2925, NRRL-ISP 5067, RIA 1044, RIA 88, UNIQEM 150, VKM Ac-1726.

Sequence accession no. (16S rRNA gene): AB184768.

228. **Streptomyces griseoluteus** Umezawa, Hayano, Maeda, Ogata and Okami 1950, 112[AL]

gri.se.o.lu′te.us. N.L. adj. *griseus* gray; L. adj. *luteus* yellow; N.L. masc. adj. *griseoluteus* grayish yellow.

Spore chains in Section *Rectiflexibiles*. Crooked or hooked spore chains may also be seen. Mature spore chains are generally short, sometimes with less than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. One observer reports

sclerotia-like bodies on the substrate mycelium of salts-starch agar and unusual morphology in the sporulating aerial mycelium. Another observer reports short chains of conidia-like spores on the substrate hyphae on yeast-malt agar and salts-starch agar.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Aerial mycelium may be poorly developed or absent on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow to yellowish brown or olive brown) on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. Yellow to yellow brown may or may not be modified by red (orange) on salts-starch agar. Reverse mycelium pigment on salts-starch agar is a pH indicator, changing from red or reddish brown to gray with the addition of 0.05 M NaOH.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Red to bluish gray pigment is found in the medium in salts-starch agar. This pigment may show the same change observed for reverse mycelium pigment with the addition of 0.05 M NaOH.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth with iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. recifensis*, AB184165, 99.9%; *S. seoulensis*, AB249970, 99.7%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1440, ATCC 12768, CBS 676.72, DSM 40392, HUT 6058, IFM 1055, NBRC 13375, JCM 4041, JCM 4765, LMG 19356, NRRL B-1315, NRRL-ISP 5392, RIA 1336, VKM Ac-976.

Sequence accession no. (16S rRNA gene): AY999751.

229. **Streptomyces griseomycini** (Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 69[AL] ("*Actinomyces griseomycini*" Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 136)

gri.se.o.my.ci′ni. N.L. adj. *griseus* gray; N.L. suff. *-mycinum*, -mycin (antibiotics produced by *Streptomyces* strains); N.L. gen. adj. *griseomycini* of gray, antibiotic (referring to gray aerial mycelium and antibiotic activity).

Spore chains in Section *Spirales* or *Retinaculiaperti*. Sporophores are short and poorly developed but are frequently coiled at the tips; true spirals are rare. Hooks and loops are of small diameter and therefore are not representative of typical *Retinaculiaperti* cultures. Mature spore chains are short, generally 3–10 spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but sporulation may be poor on oatmeal agar and glycerol-asparagine agar. Spore surface is hairy. Some smooth spores may be observed.

Color of colony: aerial mass color in the Green color series on yeast-malt and salts-starch agar (one observer placed the culture in the Gray series on these two media). Reverse side of colony is grayed yellow modified by green on yeast-malt agar and salts-starch agar; it is colorless, grayed yellow, or grayed greenish yellow on oatmeal agar and glycerol-asparagine agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. graminearus* AJ781333, 100%; *S. griseostramineus*, AB184140, 100%; *S. glaucus*, AB184665, 99.1%; *S. calvus*, AB184329, 99%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB184137.

230. **Streptomyces griseoplanus** Backus, Tresner and Campbell 1957, 536[AL]

gri.se.o.pla′nus. N.L. adj. *griseus* gray; L. adj. *planus* flat, level; N.L. masc. adj. *griseoplanus* flat, gray (referring to the restricted, flat, plane growth and grayish spore color *en masse* of the organism).

Spore chains in Section *Spirales*. Spore chains range from flexuous to spiral. Spirals are generally open: Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar and oatmeal agar; poor growth on salts-starch agar and glycerol-asparagine agar. Spore surface is warty.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar and oatmeal agar. Reverse side of colony with no distinctive pigments (grayed yellow to yellow-brown on yeast-malt agar and colorless or grayed yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar). Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, raffinose, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, D-mannitol, and rhamnose.

Type strain shows the highest sequence similarity to: *S. fimicarius*, AY999784, 100%; *S. sindenensis*, AB184759, 100%; *S. praecox*, AB184293, 100%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. anulatus*, DQ026637, 100%; *S. griseinus*, AB184205, 100%; *S. acrimycini*, AY999889, 100%; *S. badius*, AY999783, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. mediolani*, AB184674, 100%; *S. flavofuscus*, AB249935, 100%; *S. albo-*

DNA G+C content (mol%): not known.

Type strain: AS 4.1868, ATCC 19766, CBS 504.68, BCRC 13649, DSM 40009, NBRC 12779, JCM 4300, JCM 4582, NCIMB 9811, NRRL B-3064, NRRL-ISP 5009, RIA 1046, UNIQEM 152, VKM Ac-1727.

Sequence accession no. (16S rRNA gene): AY999894.

231. **Streptomyces griseorubens** (Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 65[AL] ("*Actinomyces griseorubens*" Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 144)

gri.se.o.ru′bens. N.L. adj. *griseus* gray; L. part. adj. *rubens* blushing, reddening; N.L. part. adj. *griseorubens* gray-reddening, referring to color of the aerial mycelium, vegetative mycelium and diffusible pigment.

Spore chains in Section *Spirales* or *Rectiflexibiles.* Flexuous sporophores are the dominant forms; hooks, loops, and some open spirals are present. On ISP media, this culture does not produce the long spore chains with wide diameter hooks and loops characteristic of typical *Retinaculiaperti* cultures. Mature spore chains are moderately short with 3–10, or sometimes more than 10, spores per chain. This morphology is observed on yeast-malt agar. Sporulation is poor on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny with very short spines or sometimes with smooth spores.

Color of colony: aerial mass color in the Gray color series on yeast-malt and salts-starch agar. Reverse side of colony with no distinctive pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose and raffinose. Utilization of L-arabinose and iso-inositol is doubtful.

Type strain shows the highest sequence similarity to: *S. labedae*, AB184704, 99.9%; *S. variabilis*, DQ442551, 99.9%; *S. erythrogriseus*, AJ781328, 99.9%; *S. griseoincarnatus*, AJ781328, 99.9%; *S. griseoflavus*, AJ781322, 99.7%; *S. matensis*, AB184221, 99.7%; *S. althioticus*, AY999808, 99.4%; *S. heliomycini*, AB184712, 99.3%; *S. paradoxus*, AB184628, 99.3%; *S. collinus*, AB184123, 99.2%; *S. viridodiastaticus*, AY999852, 99.2%; *S. flaveolus*, AB184764, 99.2%; *S. viridochromogenes*, DQ442555, 99.2%; *S. bellus*, AB184849, 99.1%; *S. violaceochromogenes*, AY999867, 99.1%; *S. violaceorubidus*, AJ781374, 99.1%; *S. malachitofuscus*, AB184282, 99.1%; *S. tendae*, D63873, 99.1%; *S. albogriseolus*, AJ494865, 99.1%; *S. coerulescens*, AY999720, 99.1%; *S. ambofaciens*, M27245, 99%; *S. speibonae*, AF452714, 99%; *S. longispororuber*, AB184440, 99%; *S. iakyrus*, AB184877, 99%.

Type strain: ATCC 19767, ATCC 19909, CBS 505.68, BCRC 12104, DSM 40160, NBRC 12780, INA 6124/54, JCM 4383, NCIMB 9846, NRRL B-3982, NRRL-ISP 5160, RIA 1047, UNIQEM 153, VKM Ac-1894.

Sequence accession no. (16S rRNA gene): AB184139.

232. **Streptomyces griseoruber** Yamaguchi and Saburi 1955, 220[AL]

gri.se.o.ru′ber. N.L. adj. *griseus* gray; L. adj. *ruber* red; N.L. masc. adj. *griseoruber* grayish red.

Spore chains in Section *Spirales* or *Retinaculiaperti.* Open or tight spirals are produced at the ends of moderately long spore chains of 10 to 50 or more spores per chain. Spirals are often incomplete, forming only 1 or 2 turns or a hook at the end of the spore chain. Straight to flexuous chains without hooks or spirals are also present. This morphology is usually best on glycerol-asparagine agar, but may also be observed on yeast-malt agar, oatmeal agar, and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red or Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The color is represented by tab 5fe (light grayish reddish brown) from the Gray color series and tab 5ge (also light grayish reddish brown) from the Red color series. Reverse side of colony is yellow to yellow-brown plus red (reddish orange or reddish brown on yeast-malt agar, oatmeal agar, and salts-starch agar; light yellowish pink on glycerol-asparagine agar). Substrate mycelium pigment is a pH indicator changing from reddish orange to purple with addition of 0.05 M NaOH and from reddish orange to yellowish orange with addition of 0.05 M HCl.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow to red pigment (depending upon pH) may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive, changing from orange to purple with addition of 0.05 M NaOH and from orange to yellow with

addition of 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, D-mannitol, and raffinose.

Type strain shows the highest sequence similarity to: *S. antibioticus*, AY999776, 99.3%; *S. cinnabarinus*, AB184266, 99%; *S. cellostaticus*, AB184192, 99%.

Sequence accession no. (16S rRNA gene): AB184209.

233. **Streptomyces griseorubiginosus** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 62[AL] ("*Actinomyces griseorubiginosus*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 193)

gri.se.o.ru.bi.gin.o′sus. N.L. adj. *griseus* gray; N.L. adj. *robiginosus* (*sic*) rusty; N.L. masc. adj. *griseorubiginosus* gray, rusty (referring to the gray aerial mycelium and rosy reddish vegetative mycelium and diffusible pigment on a chemically defined medium).

Spore chains in Section *Rectiflexibiles*. The very long spore chains with more than 50 spores per chain may also form a few open loops and terminal hooks suggestive of *Retinaculiaperti* morphology. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth; two observers found only smooth spores, a third observer found both smooth and spiny spores. Long aerial hyphae may be entangled, forming knots and sclerotia-like bodies on yeast-malt agar, oatmeal agar, glycerol-asparagine agar, or Czapek's sucrose agar. One observer records *in situ* germination of spores in 7 d on Czapek's sucrose agar.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray to 3fe, light brownish gray or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is brown, grayish reddish brown or dark brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator changing from yellowish brown to gray with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red or reddish brown pigment is found in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar and yellow or yellowish brown pigment is found in the medium in salts-starch agar. This pigment is pH-sensitive, showing the same changes noted for reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. phaeopurpureus*, DQ026666, 100%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23627, ATCC 25459, CBS 692.69, BCRC 12124, DSM 40469, NBRC 13047, INA 7712, JCM 4481, NRRL B-12384, NRRL-ISP 5469, RIA 1239, VKM Ac-1203.

Sequence accession no. (16S rRNA gene): AJ781339.

234. **Streptomyces griseosporeus** Niida and Ogasawara 1960, 23[AL]

gri.se.o.spo′re.us. N.L. adj. *griseus* gray; N.L. n. *spora* a spore; N.L. masc. adj. *griseosporeus* gray spored.

Spore chains in Section *Retinaculiaperti*. Spore chains may be flexuous or in imperfect spirals, hooks and loops. Flexuous chains are common. Mature spore chains are moderately long with 10–50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (2fe or e, moderate gray; 3fe, light brownish gray; or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow or sometimes light yellowish brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27435, CBS 137.72, CBS 759.72, DSM 40562, HAMBI 1009, NBRC 13458, IMET 43543, JCM 4766, NRRL B-12498, NRRL-ISP 5562, RIA 1419, VKM Ac-1731.

Sequence accession no. (16S rRNA gene): AB184419.

235. **Streptomyces griseostramineus** (Preobrazhenskaya, Kudrina, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 65[AL] ("*Actinomyces griseostramineus*" Preobrazhenskaya, Kudrina, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 155)

gri.se.o.stra.mi′ne.us. N.L. adj. *griseus* gray; L. adj. *stramineus* of straw, here straw-colored; N.L. masc. adj. *griseostramineus* gray, straw-colored (referring to the gray aerial mycelium and straw-yellow vegetative mycelium on a chemically defined medium).

Spore chains in Section *Spirales*. Short spore chains may form tight spirals of only a few turns on yeast-malt agar and salts-starch agar. Hooks and loops suggestive of Section *Retinaculiaperti* may also be found on these media and

on oatmeal agar. Mature spore chains are short, generally 3–10 spores per chain. This morphology is seen on yeast-malt agar and salts-starch agar; sporulation may be poor on oatmeal agar and glycerol-asparagine agar. Spore surface is hairy to spiny: appendages are shorter than characteristic hairs, but longer and more flexuous than typical spines.

Color of colony: aerial mass color in the Green color series on yeast-malt agar and salts-starch agar. Reverse side of colony with no distinctive pigment (grayed yellow or grayed yellow modified by green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose. Variable reports on growth with raffinose.

Type strain shows the highest sequence similarity to: *S. griseomycini*, AB184137, 100%; *S. graminearus* AJ781333, 100%; *S. calvus*, AB184329, 99%; *S. glaucus*, AB184665, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19768, ATCC 23628, CBS 506.68, BCRC 12075, CECT 3273, DSM 40161, NBRC 12781, INA 10381, JCM 4385, NRRL B-5422, NRRL-ISP 5161, RIA 1048, UNIQEM 154, VKM Ac-968.

Sequence accession no. (16S rRNA gene): AB184140.

236. **Streptomyces griseoverticillatus** (Shinobu and Shimada 1962) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces griseoverticillatus*" Shinobu and Shimada 1962, 174; "*Verticillomyces griseoverticillatus*" Shinobu 1965; *Streptoverticillium griseoverticillatum* Locci, Baldacci and Petrolini Baldan 1969, 59)

gri.se.o.ver.ti.cil.la′tus. N.L. adj. *griseus* gray; L. masc. n. *verticillus* whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *griseoverticillatus* gray and whorled.

Spore chains in Section *Verticillati*, umbellate monoverticillate (biverticillate). Mature spore chains are short with 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (usually 4ec, grayish yellowish pink; sometimes 4ge, light grayish reddish brown; 4ie, light brown; or 3ca, pale orange-yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is yellowish brown or orange-yellow on yeast-malt agar; grayish yellowish pink to light olive brown on oatmeal agar; yellowish brown to strong brown on salts-starch agar; pale or grayish yellow on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and iso-inositol are utilized for growth. Utilization of D-fructose is doubtful. No growth or only traces of growth with L-arabinose, D-xylose, rhamnose, sucrose, raffinose, and D-mannitol.

For sequence similarity, see type strain of *Streptomyces cinnamoneus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27436, CBS 721.72, BCRC 12430, DSM 40507, NBRC 13420, JCM 4202, JCM 4767, NRRL B-12432, NRRL-ISP 5507, PCM 2351, RIA 1381, VKM Ac-883.

Sequence accession no. (16S rRNA gene): AB184862.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces griseoverticillatus* is proposed as a *nomen revictum* (basonym: "*Streptomyces griseoverticillatus*" Shinobu and Shimada (1962).

According to Hatano et al. (2003), *Streptomyces griseoverticillatus* (Shinobu and Shimada 1962) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces cinnamoneus* (Benedict et al. 1952) Witt and Stackebrandt 1991.

237. **Streptomyces griseoviridis** Anderson, Ehrlich, Sun and Burkholder 1956, 114[AL]

gri.se.o.vi′ri.dis. N.L. adj. *griseus* gray; L. adj. *viridis* green; N.L. masc. adj. *griseoviridis* gray-green.

Spore chains in Section *Spirales*. Some open spirals have only one or two turns or are poorly developed suggesting *Retinaculiaperti* morphology. Spore chains are moderately long with 10–50 spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink to pale orange yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer placed this culture in the Yellow color series. The original description (Anderson et al., 1956) included the following statement: "Aerial mycelium is white to pink-tan, ping-gray, or brown or occasionally greenish". The greenish color was not observed on ISP media. Reverse side of colony is grayed yellow to olive brown or dark brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator or is changed only slightly by 0.05 M NaOH or HCl.

Color in medium: melanoid pigments are not found in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment in medium, or only trace of yellow, in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and rhamnose are utilized for growth. Utilization of D-fructose is doubtful. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. aurantiogriseus*, AY999793, 99.4%; *S. coelicolor*, DQ442496, 99.3%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1418, ATCC 23920, CBS 904.68, DSM 40229, HAMBI 1086, NBRC 12874, JCM 4250, JCM 4643, KCTC 9780, LMG 19321, NCIMB 9853, NRRL 2427, NRRL-ISP 5229, RIA 1170, VKM Ac-622.

Sequence accession no. (16S rRNA gene): AY999807.

238a. **Streptomyces griseus subsp. griseus** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 948[AL] ("*Actinomyces griseus*" Krainsky 1914, 662)

gri′se.us. N.L. masc. adj. *griseus* gray.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (2db, pale yellow, or 1½db–1½ec, pale greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayed yellow to olive brown or light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in tyrosine agar, but not in peptone-yeast-iron agar or tryptone-yeast broth. No pigments other than traces of yellow are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, iso-inositol, rhamnose, or raffinose.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.8%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.8%; *S. cinereorectus*, AB184646, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. sindenensis*, AB184759, 99.7%; *S. mediolani*, AB184674, 99.7%; *S. fimicarius*, AY999784, 99.7%; *S. lipmanii*, AB184148, 99.7%; *S. fulvorobeus*, AB184711, 99.7%; *S. anulatus*, DQ026637, 99.7%; *S. praecox*, AB184293, 99.7%; *S. flavofuscus*, AB249935, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. pluricolorescens*, DQ442540, 99.7%; *S. griseinus*, AB184205, 99.7%; *S. microflavus*, DQ445795, 99.7%; *S. griseoplanus*, AY999894, 99.7%; *S. rubiginosohelvolus*, AB184240, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. badius*, AY999783, 99.7%; *S. griseolus*, AB184768, 99.6%; *S. luridiscabiei*, AF361784, 99.6%; *S. floridae*, AB184656, 99.6%; *S. albovinaceus*, AB249958, 99.6%; *S. acrimycini*, AY999889, 99.6%; *S. baarnensis*, EF178688, 99.6%; *S. flavovirens*, DQ026635, 99.5%; *S. halstedii*, EF178695, 99.5%; *S. californicus*, AB184755, 99.5%; *S. parvus*, DQ442537, 99.5%; *S. flavogriseus*, AJ494864, 99.4%; *S. pulveraceus*, AB184806, 99.4%; *S. yanii*, AB006159, 99.4%; *S. finlayi*, AY999788, 99.3%; *S. globisporus* subsp. *globisporus*, EF178686, 99.3%; *S. bacillaris*, AB184439, 99.2%; *S. nitrosporeus*, EF178680, 99.2%; *S. olivoviridis*, AB184227, 99.2%; *S. atroolivaceus*, AJ781320, 99.2%; *S. clavifer*, DQ026670, 99.2%; *S. gelaticus*, DQ026636, 99.1%; *S. atratus*, DQ026638, 99.1%; *S. mutomycini*, AB249951, 99%; *S. sanglieri*, AB249945, 99%; *S. albolongus*, AB184425, 99%; *S. celluloflavus*, AB184476, 99%; *S. griseobrunneus*, AB249912, 99%.

Sequence accession no. (16S rRNA gene): AY207604.

Further comments: according to Liu et al. (2005b), *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 emend. Liu et al. 2005b is an earlier heterotypic synonym of *Streptomyces argenteolus* Tresner et al. 1961, an earlier heterotypic synonym of *Streptomyces caviscabies* Goyer et al. 1996, and an earlier heterotypic synonym of *Streptomyces setonii* (Millard and Burr 1926) Waksman 1953.

According to Guo et al. (2008), *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 is an earlier heterotypic synonym of *Streptomyces erumpens* Calot and Cercós 1963.

According to Guo et al. (2008), *Streptomyces argenteolus* Tresner et al. 1961 is not a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948.

According to Guo et al. (2008), *Streptomyces caviscabies* Goyer et al. 1996 is not a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948.

238b. **Streptomyces griseus subsp. alpha** (Ciferri 1927) Pridham 1970, 37[AL] ["*Actinomyces albus* subsp. alpha" (*sic*) Ciferri 1927, 83]

al′pha. L. n. *alpha*, alpha, first letter of the Greek alphabet.

Spore chains are typically flexuous; grows poorly on Czapek's solution agar. Exhibits slight anti-bacterial activity; inhibited by streptomycin. Reported as a cause of musty odor in cacao beans (*Theobroma cacao* L.).

For sequence similarity, see type strain of *Streptomyces microflavus.*

Source: not known.

DNA G+C content (mol%): not known.

Type strain: CBS 219.25, DSM 40937, NBRC 15421, JCM 5078, LMG 19953, NRRL B-2249.

Sequence accession no. (16S rRNA gene): AB184668.

Further comments: according to Lanoot et al. (2005b), *Streptomyces griseus* subsp. *alpha* (Ciferri 1927) Pridham 1970 is a later heterotypic synonym of *Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948 emend. Lanoot et al. 2005b.

238c. **Streptomyces griseus subsp. cretosus** Pridham 1970, 37[AL] ("*Oospora cretacea*" Krüger 1905, 286; "*Actinomyces cretaceus*" Krasil'nikov 1941, 34; "*Streptomyces cretaceus*" Waksman 1950, 143)

cre.tos′us. L. masc. adj. *cretosus* chalky.

Exhibits slight anti-microbial activity; inhibited by streptomycin; moderate growth observed on Czapek's solution agar.

For sequence similarity, see type strain of *Streptomyces microflavus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27903, CBS 137.21, CBS 758.72, DSM 40561, NBRC 13457, JCM 4742, KCTC 9079, LMG 19946, NRRL B-2252, NRRL-ISP 5561, RIA 1418, VKM Ac-712.

Sequence accession no. (16S rRNA gene): AB184418.

Further comments: according to Lanoot et al. (2005b), *Streptomyces griseus* subsp. *cretosus* Pridham 1970 is a later heterotypic synonym of *Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948 emend. Lanoot et al. 2005b.

238d. **Streptomyces griseus subsp. solvifaciens** Pridham 1970, 38[AL]

sol.vi.fa′ci.ens. L. v. *solvo* to loosen; L. v. *facio* to make; N.L. part. adj. *solvifaciens* making loose, dissolving, referring to the lytic activity of actinomycetin.

Spore chains are typically flexuous; poor growth is seen on Czapek's solution agar. Exhibits anti-bacterial and anti-fungal activity; produces actinomycetin, now considered a general term for a number of different lytic enzymic anti-bacterial and anti-viral factors; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. hydrogenans*, AB184868, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. champavatii*, DQ026642, 99.9%; *S. canescens*, AB184117, 99.9%; *S. sampsonii*, D63871, 99.7%; *S. koyangensis*, AY079156, 99.6%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: JCM 5079, DSM 40933, NBRC 13689, NRRL B-1561.

Sequence accession no. (16S rRNA gene): AB249915.

Further comments: according to Guo et al. (2008), *Streptomyces griseus* subsp. *solvifaciens* Pridham 1970 should be removed from *Streptomyces griseus*. However, no formal proposition is made in the paper by Guo et al. (2008).

239. **Streptomyces guanduensis** Xu, Wang, Cui, Huang, Liu, Zheng and Goodfellow 2006, 1114[VP]

gu.an.du.en′sis. N.L. masc. adj. *guanduensis* of or belonging to Guandu, the source of the soil from which the type strain was isolated.

Acidophilic streptomycete; forms branched substrate and aerial hyphae. Smooth-surfaced spores are borne in flexuous spore chains. Deep-brown colonies that carry a white to gray aerial spore mass are formed on oatmeal agar, ISP medium 9 supplemented with glucose (1%, w/v), and on yeast extract-malt extract agar. Diffusible pigments are not formed and melanin pigments are not produced on peptone-yeast extract-iron agar or tyrosine agar. Degrades Tween 80, but not adenine, guanine, starch, or xanthine. Cellobiose, D-galactose, D-glucose, D-inulin, D-lactose, D-mannitol, and D-salicin (each at 1%, w/v), and adipic acid and L-phenylalanine (each at 0.1%, w/v) are used as sole carbon sources for energy and growth, but adonitol and D-sorbitol (each at 1%, w/v), and L-alanine, DL-aminobutyric acid, L-arginine, α-L-aspartic acid, L-cysteine, L-valine, sodium acetate, sodium citrate, and sodium oxalate (each at 0.1%, w/v) are not. Growth occurs at temperatures between 20 and 37°C, but not at 15°C, and at pH values from 4.5–7.0, but not at pH 3.5. Does not grow in the presence of 5% (w/v) NaCl. The organism is sensitive to filter-paper discs soaked in the following (μg/ml unless indicated): acetylspiramycin (15), carbenicillin (10), cephalothin (30), ciprofloxacin (5), doxycycline hydrochloride (30), erythromycin (15), josamycin (15), kanamycin sulfate (30), minocyclin hydrochloride (30), and tobramycin sulfate (10), but not to amoxycillin (10), ampicillin (10), azitrhomycin (30), aztreonam (30), penicillin G (10 IU/ml), or sulfamethoxazole (25). Additional properties are shown in Table 264. Chemotaxonomic properties are typical of members of the genus *Streptomyces*.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. yeochonensis* NRRL B-24245^T, 18.7%; *S. paucisporeus* JCM 13276^T, 14.9%; *S. rubidus* JCM 13277^T, 21.4%; *S. yanglinensis* JCM 13275^T, 23.1%.

Source: the type strain was isolated from soil from Guandu.

DNA G+C content (mol%): 72.7.

Type strain: 701, CGMCC 4.2022, JCM 13274.

Sequence accession no. (16S rRNA gene): AY876942.

240. **Streptomyces hachijoensis** (Hosoya, Komatsu, Soeda and Sonoda 1952) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces hachijoensis*" Hosoya, Komatsu, Soeda and Sonoda 1952, 508; *Streptoverticillium hachijoense* Locci, Baldacci and Petrolini Baldan 1969, 59)

ha.chi.jo.en′sis. N.L. masc. adj. *hachijoensis* or or belonging to Hachijo (named for the place of origin, Hachijo Jima, a small island in the Pacific Ocean).

Spore chains in Section *Verticillati*. Both monoverticillate and umbellate monoverticillate (biverticillate) spore chains are found. Mature spore chains are short, generally 3–10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment in medium, or only trace of yellow, in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and iso-inositol are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, D-xylose, D-mannitol, D-fructose, rhamnose, and raffinose.

For sequence similarity, see type strain of *Streptomyces cinnamoneus*.

Source: isolated from soil from Hachijo Jima, a small island in the Pacific Ocean.

DNA G+C content (mol%): not known.

Type strain: ATCC 19769, CBS 507.68, BCRC 12419, CECT 3260, DSM 2011, DSM 40114, NBRC 12782, JCM 4331, JCM 4583, NRRL B-3106, NRRL-ISP 5114, RIA 1049, UNIQEM 155, VKM Ac-191.

Sequence accession no. (16S rRNA gene): AB184141.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces hachijoensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces hachijoensis*" Hosoya et al. (1952).

According to Hatano et al. (2003), *Streptomyces hachijoensis* (Hosoya et al. 1952) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces cinnamoneus* (Benedict et al. 1952) Witt and Stackebrandt 1991.

241. **Streptomyces hainanensis** Jiang, Tang, Wiese, Xu, Imhoff and Jiang 2007, 2697[VP]

hai.nan.en′sis. N.L. masc. adj. *hainanensis* of or pertaining to Hainan, a province of south China, from where the type strain was isolated.

Spore chains are spiral or looped. Spores are elliptical or short rod-shaped. Spore surface is smooth. Aerial mycelia are white and pink white to pink gray. Vegetative mycelia are pale to deep orange yellow. Produces light brown to orange yellowish soluble pigments. Gelatin liquefaction, milk coagulation and peptonization, arginase, phenylalanine deaminase, DNase, and melanin production are negative. Starch hydrolysis, arginine decarboxylase, nitrate reduction, gas production from nitrate, growth on cellulose, and H_2S production are positive. Glucose, cellobiose, starch, esculin, galactoside, and urea are utilized; acids are not produced from the five carbon sources. Galactose, mannose, fructose, arabinose, xylose, ribose, rhamnose, sucrose, lactose, maltose, melibiose, raffinose, turanose, melezitose, sorbin, dextrin, mycose, salicin, adonitol, inositol, mannitol, sorbitol, xylitol, galactitol, erythritol, amygdaloside, sodium citrate, sodium acetate, gluconate, malonate, tartrate, lysine, ornithine, and acetamide are not utilized. Optimal growth occurs at pH 7.0 (range pH 6.0–9.0) and without NaCl (range 0–10% NaCl). Resistant to penicillin G (10 IU), amoxycillin/clavulanic acid (20/10 µg), novobiocin (30 µg), rifampin (5 µg), and ampicillin (10 µg), and sensitive to erythromycin (15 µg IU), gentamicin (10 µg), kanamycin (30 µg), tetracycline (30 µg), vancomycin (30 µg), midecamycin (15 µg), clindamycin (2 µg), sulfamethoxazole/trimethoprim (23.75/1.25 µg), chloramphenicol (30 µg), polymyxin B (300 IU), and norfloxacin (10 µg). Cell wall contains LL-A_2pm, trace *meso*-A_2pm, and glycine. Whole-cell hydrolysates contain galactose and xylose. Main phospholipids are phosphatidylethanolamine and diphosphatidylglycerol (phospholipid type II). The predominant menaquinones are MK-9(H_4) (45.4%), MK-9(H_6) (14.0%), MK-9(H_8) (13.6%), and MK-10(H_0) (27.0%). Fatty acid composition comprises $C_{15:0}$ iso (1.1%), $C_{16:0}$ iso (30.9%), $C_{16:1}\omega7c$/$C_{16:1}\omega6c$ (2.1%), $C_{16:0}$ (13.7%), $C_{17:1}$ iso$\omega9c$ (1.4%), $C_{17:0}$ iso (2.8%), $C_{17:0}$ anteiso (10.8%), $C_{17:1}\omega8c$ (7.1%), cyclo-$C_{17:0}$ (1.4%), $C_{17:0}$ (5.6%), $C_{18:0}$ anteiso/$C_{18:2}\omega6,9c$ (9.7%), $C_{18:1}\omega9c$ (4.9%), $C_{18:0}$ (1.2%), and $C_{17:1}$ iso$\omega9c$/$C_{16:0}$ 10-methyl (1.4%).

Type strain shows no sequence similarity over 99%.

Source: the type strain was isolated from a soil sample collected from evergreen broadleaf forest in Wuzhi Mountain, Hainan Province, China.

DNA G+C content (mol%): 73.4.

Type strain: YIM 47672, CCTCC AA 205017, DSM 41900.

Sequence accession no. (16S rRNA gene): AM398645.

242. **Streptomyces halstedii** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 953[AL] ("*Actinomyces halstedii*" Waksman and Curtis 1916, 124)

hal.ste′di.i. N.L. gen. masc. n. *halstedii* of Halsted, named for Byron David Halsted (1852–1918) of Rutgers University.

Spore chains Section *Rectiflexibiles*. Spore chains are predominantly flexuous, but many hooks and some irregular coils similar to *Rectiflexibiles* morphology are found on yeast-malt agar and glycerol-asparagine agar. Spore chains are short, 3–10 spores per chain, on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Sporulation may be poor, especially on oatmeal agar. Since the original characterization by Waksman (1916) describes closed spirals 7–10 µm in diameter, the short flexuous or hooked chains may be atypical. Spore surface is smooth. Fragmentation of substrate mycelium is noted by one observer.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony has no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and D-fructose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. griseolus*, AB184768, 100%; *S. cinereorectus*, AB184646, 99.8%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.7%; *S. praecox*, AB184293, 99.7%; *S. anulatus*, DQ026637, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. fimicarius*, AY999784, 99.7%; *S. lipmanii*, AB184148, 99.7%; *S. flavofuscus*, AB249935, 99.7%; *S. microflavus*, DQ445795, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. fulvorobeus*, AB184711, 99.7%; *S. mediolani*, AB184674, 99.6%; *S. badius*, AY999783, 99.6%; *S. acrimycini*, AY999889, 99.6%;

DNA G+C content (mol%): not known.

Type strain: ATCC 10897, ATCC 19770, CBS 508.68, BCRC 13680, CECT 3328, DSM 40068, HAMBI 993, NBRC 12783, IMET 40322, JCM 4584, NCIMB 9839, NRRL B-1238, NRRL-ISP 5068, RIA 1050, UNIQEM 156, VKM Ac-1768.

Sequence accession no. (16S rRNA gene): EF178695.

243. **Streptomyces hawaiiensis** Cron, Whitehead, Hooper, Heinemann and Lein 1956, 63[AL]

ha.wai.i.en′sis. N.L. masc. adj. *hawaiiensis* of or belonging to Hawaii, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*, but on some media short or poorly developed spore chains are flexuous or have hooks, loops or open spirals resembling *Retinaculiaperti* morphology. Mature spore chains are moderately short with 3–10, or sometimes more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the White color series on salts-starch agar and glycerol-asparagine agar; Yellow or White series on yeast-malt agar and oatmeal agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast broth; pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth; utilization of D-xylose is doubtful.

Type strain shows the highest sequence similarity to: *S. massasporeus*, AB184152, 99.7%; *S. arenae*, AB249977, 99.7%; *S. purpurascens*, AJ399486, 99.5%; *S. luteogriseus*, AB184379, 99.4%; *S. indiaensis*, AB184553, 99.3%; *S. janthinus*, AB184851, 99.3%; *S. violaceus*, AB184315, 99.3%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.3%; *S. coerulescens*, AY999720, 99.2%; *S. bellus*, AB184849, 99.2%; *S. roseoviolaceus*, AJ399484, 99.2%; *S. flavoviridis*, AB184842, 99.1%; *S. pilosus*, AB184161, 99%; *S. afghaniensis*, AJ399483, 99%; *S. africanus*, AY208912, 99%; *S. lomondensis*, AB184673, 99%; *S. levis*, AB184670, 99%; *S. coeruleorubidus*, AY999719, 99%.

Source: isolated from soil from Hawaii.

DNA G+C content (mol%): not known.

Type strain: ATCC 12236, ATCC 19771, CBS 509.68, BCRC 13653, DSM 40042, IFM 1071, NBRC 12784, IMET 43082, JCM 4172, JCM 4585, LMG 5975, NCIMB 9410, NRRL B-1988, NRRL-ISP 5042, PCM 2315, RIA 1051, UNIQEM 157, VKM Ac-1761.

Sequence accession no. (16S rRNA gene): AB184143.

244. **Streptomyces hebeiensis** Xu, Li, Wu, Wang, Xu and Jiang 2004a, 730[VP]

he.bei.en′sis. N.L. masc. adj. *hebeiensis* of or pertaining to Hebei, a province in northern China where the sample yielding the type strain was collected.

Aerial mycelium and substrate mycelium are well developed. Aerial mycelium at maturity forms long, straight to *Rectiflexibiles* spore chains composed of nonmotile and coccoid spores with a warty surface. Diffusible pigments are produced on several media. The pigment is not a pH indicator or is changed only slightly with addition of 0.05 M HCl in ISP 5 and ISP 6. Colony color is medium-dependent. Casein and xanthine can be metabolized, but adenine and pectin cannot. Tests for gelatin, nitrate reduction, and melanin production are positive and tests for H_2S production and peptonization of milk are negative. Galactose, lactose, mannose, maltose, xylose, sorbitol, sodium citrate, sodium acetate, oxalate, starch, and glycerol are utilized as sole carbon and energy sources, but cellulose and xylan are not. Acid is formed from mannose and starch, but not from arabinose, fructose, galactose, glucose, inositol, lactose, mannitol, maltose, rhamnose, raffinose, sucrose, sorbitol, xylose, sodium citrate, sodium acetate, oxalate, or glycerol. L-Histidine and L-hydroxyproline can be used as sole carbon and nitrogen sources. Grows well at 27, 30, and 37°C but does not grow at 45 or 10°C. Grows in the presence of 4 or 7% NaCl and 0.1% phenol. Diagnostic amino acid of peptidoglycan is LL-A_2pm with trace amounts of *meso*-A_2pm. Whole-cell hydrolysates contain glucose and small quantities of xylose, galactose, and arabinose. The menaquinones are MK9(H_4) (4.6%), MK-9(H_6) (60%), MK-9(H_8) (30.7%), and MK-9(H_{10}) (4.7%) and phosphatidylethanolamine is the diagnostic phospholipid.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): 71.4.

Type strain: YIM 001, CCTCC AA 203005, CIP 107974, DSM 41837, JCM 12696. *Sequence accession no. (16S rRNA gene):* AY277529.

245. **Streptomyces heliomycini** (*ex* Braznikova, Uspenskaya, Sokolova, Preobrazhenskaya, Gause, Ukholina, Shorin, Rossolimo and Vertogradova 1958) Preobrazhenskaya 1986, 574[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and

Maximova 1983.) ("*Actinomyces flavochromogenes* subsp. *heliomycini*" Braznikova, Uspenskaya, Sokolova, Preobrazhenskaya, Gause, Ukholina, Shorin, Rossolimo and Vertogradova 1958)

he.li.o.my.ci′ni. N.L. n. *heliomycinum* heliomycin; N.L. gen. n. *heliomycini* of heliomycin, intended to mean heliomycin producing.

Spore chains are spiral (*Spirales*); spore surface is warty, hairy, and spiny. On mineral agar 1, starch-ammonia agar: aerial mycelium is green-gray; substrate mycelium is yellow, brown-orange; no diffusible pigment. On glycerol-nitrate agar, glycerol-asparagine agar: aerial mycelium is gray; substrate mycelium is dark yellow, brown yellowish, dark gray; no diffusible pigment. On oatmeal agar: aerial mycelium is gray; substrate mycelium is dark yellow, yellow brown; no diffusible pigment. On organic agar 2: aerial mycelium is gray, dark gray, green gray; substrate mycelium is brownish yellow, yellow brown; sometimes no diffusible pigment. Melanoid pigments are not formed. Utilization of glucose, sucrose, xylose, inositol, mannitol, fructose, and rhamnose. Antibiotic: geliomycin.

Type strain shows the highest sequence similarity to: *S. griseorubens*, AB184139, 99.3%; *S. griseoflavus*, AJ781322, 99.3%; *S. atrovirens*, DQ026672, 99.2%; *S. matensis*, AB184221, 99.2%; *S. griseoincarnatus*, AJ781328, 99.1%; *S. erythrogriseus*, AJ781328, 99.1%; *S. labedae*, AB184704, 99.1%; *S. variabilis*, DQ442551, 99.1%; *S. ambofaciens*, M27245, 99.1%; *S. albaduncus*, AY999757, 99%; *S. griseoloalbus*, AB184275, 99%; *S. lienomycini*, AJ781353, 99%.

Sequence accession no. (16S rRNA gene): AB184712.

246. **Streptomyces helvaticus** (Krasil'nikov, Korenyako and Nikitina *in* Krasil'nikov 1965) Pridham 1970, 18[AL] ("*Actinomyces helvaticus*" Krasil'nikov, Korenyako and Nikitina *in* Krasil'nikov 1965, 224)

helv.va′ti.cus. N.L. n. *Helvetia* Switzerland; N.L. masc. adj. orth. var. *helvaticus* of or belonging to Switzerland.

Spore chains in Section *Retinaculiaperti* to *Spirales*. Straight to flexuous spore chains may also be common, especially when short spore chains are produced. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Sporulating aerial mycelium may be poorly developed or absent on yeast-malt agar. Spore surface is smooth.

Color of colony: aerial mass color probably in the Red color series (3ca, pale orange-yellow to 4ca, light yellowish pink) on oatmeal agar and salts-starch agar when optimum sporulation occurs. Aerial mass color may also appear to be white or yellow (2ba or 2db, pale yellow) on oatmeal agar and salts-starch agar. Aerial mycelium is poorly developed on yeast-malt agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (light yellow or pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose and iso-inositol are utilized for growth. Utilization of D-fructose is doubtful. No growth or only traces of growth with rhamnose, sucrose, raffinose, and D-mannitol.

Type strain shows the highest sequence similarity to: *S. flavidovirens*, AB184270, 100%; *S. chryseus*, AY999787, 100%; *S. albidochromogenes*, AB249953, 99.9%; *S. enissocaesilis*, AB249930, 99.1%.

DNA G+C content (mol%): not known.

Type strain: ATCC 19841, CBS 683.72, DSM 40431, NBRC 13382, INMI 1013-B, JCM 4768, NRRL B-12365, NRRL-ISP 5431, RIA 1343, VKM Ac-192.

Sequence accession no. (16S rRNA gene): AB184367.

247. **Streptomyces herbaricolor** Kawato and Shinobu 1959, 114[AL]

her.ba.ri.co′lor. L. n. *herbarius* one skilled in plants, a botanist; L. n. *color* color; N.L. adj. *herbaricolor* grass colored, green (referring to the grass green diffusible pigment produced by the organism on chemically defined media).

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain on yeast-malt agar and glycerol-asparagine agar. Sporulation aerial mycelium is poorly developed or absent on oatmeal agar and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on glycerol-asparagine agar and yeast-malt agar. Aerial mycelium is poorly developed on all ISP media; mass color cannot be determined on oatmeal agar or salts-starch agar. Reverse side of colony: substrate mycelium may be grayish yellow to olive brown or brown or it may contain an additional pH-sensitive pigment with a color range from pale purple or pale purplish pink to green or greenish blue. When this pigment is present, addition of 0.05 M NaOH changes color from violet-red to green or blue and this change is reversed by addition of 0.05 M HCl. The pH-sensitive mycelial pigment was found by one observer in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed or occur only in trace amounts in peptone-yeast-iron agar and tyrosine agar. Pigment may or may not be formed in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. When formed, this pigment shows the same pH range found in the transient substrate pigment.

D-Glucose, L-arabinose, sucrose, D-xylose, D-fructose, and raffinose are utilized for growth. No growth or only trace of growth on iso-inositol, D-mannitol, and rhamnose.

Type strain shows the highest sequence similarity to: *S. indigoferus*, AB184214, 100%; *S. aburaviensis*, AY999779, 99.6,%; *S. purpureus*, AJ781324, 99.6%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.5%; *S. purpeofuscus*, AJ781364, 99.2%; *S. xanthocidicus*, AY999858, 99.2%. Type strain shows the highest sequence similarity to following

Kitasatospora species: *Kitasatospora kifunensis*, AB022874, 99.3%; *Kitasatospora nipponensis*, AY442263, 99%; *Kitasatospora gansuensis*, AY442265, 99%.

248. **Streptomyces hiroshimensis** (Shinobu 1955) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces hiroshimensis*" Shinobu 1955; "*Verticillomyces hiroshimensis*" Shinobu 1965; *Streptoverticillium hiroshimense* Farina and Locci 1966, 51)

hi.ro.shim.en′sis. N.L. masc. adj. *hiroshimensis* of or pertaining to Hiroshima.

Spore chains in Umbellate Monoverticillate (=*Streptomyces* Section *Verticillati*, biverticillate). Mature spore chains are short, generally 3–10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 14–21 d. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony is grayed yellow, modified by red on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; or yellow-brown is modified by red on yeast-malt agar. Substrate pigment is not a pH indicator (one observer reports slight change from pink to brown with NaOH on oatmeal agar).

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast broth; pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, iso-inositol, and D-fructose are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. caeruleus*, EF178675, 99.7%; *S. cinnamoneus*, AB184850, 99.7%; *S. abikoensis*, AB184537, 99.5%; *S. blastmyceticus*, AY999802, 99.5%; *S. aureoversilis*, AB184855, 99.5%; *S. pseudoechinosporeus*, AB184100, 99.5%; *S. lilacinus*, AB184819, 99.4%; *S. ardus*, AB184864, 99.2%; *S. biverticillatus*, AJ781381, 99%; *S. albireticuli*, AB184881, 99%; *S. sapporonensis*, AB184508, 99%; *S. werraensis*, DQ442558, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19772, CBS 510.68, BCRC 13375, CECT 3261, DSM 40037, HUT 6033, NBRC 12785, NBRC 3839, IMET 43546, JCM 4098, JCM 4586, KCTC 9781, NBRC 3720, NCIMB 9838, NRRL B-1823, NRRL B-5484, NRRL-ISP 5037, RIA 1052, RIA 592, UNIQEM 158, VKM Ac-902.

Sequence accession no. (16S rRNA gene): AB184789.

Further comments: according to Hatano et al. (2003), *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces aureoversilis* corrig. (Locci et al. 1969) Witt and Stackebrandt 1991, of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991, of *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991, of *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991, of *Streptomyces rectiverticillatus* (Krasil'nikov and Yuan 1965) Witt and Stackebrandt 1991, of *Streptomyces roseoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991, of *Streptomyces salmonis* (Baldacci et al. 1966) Witt and Stackebrandt 1991, and of *Streptomyces spitsbergensis* Wieczorek et al. 1993. Hatano et al. (2003) also propose that *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991 be a heterotypic synonym of "*Streptomyces fervens* subsp. *melrosporus*" (NBRC 15920), and of "*Streptoverticillium rubrochlorinum*" (NBRC 14694). In the paper by Hatano et al. (2003), "*Streptomyces fervens* subsp. *melrosporus*" is not in quotes. However, this name has no standing in bacterial nomenclature.

249. **Streptomyces hirsutus** Ettlinger, Corbaz and Hütter 1958a, 344[AL]

hir.su′tus. L. masc. adj. *hirsutus* shaggy, bristly, with stiff hairs.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Flexuous spore chains and chains terminating in hooks and loops are common; well developed spirals of more than 1 or 2 turns are rare. Mature spore chains generally have 10–30 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Green color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow to grayed greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. cyanoalbus*, AB184882, 100%; S. *prasinus*, DQ026658, 99.1%; *S. bambergiensis*, AB184869, 99.1%.

Sequence accession no. (16S rRNA gene): AB184844.

250. **Streptomyces humidus** Nakazawa and Shibata *in* Imamura, Hori, Nakazawa, Shibata, Tatsuoka and Miyake 1956, 648[AL]

hu′mi.dus. L. masc. adj. *humidus* wet, damp, moist.

Spore chains in Section *Spirales* with many incomplete spirals resembling *Retinaculiaperti* morphology. Spore chains short to moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Spore surface is smooth. Although the original description reports production of black, moist (hygroscopic) areas on mature aerial mycelium, this was not recorded on ISP reports.

Color of colony: aerial mass color in the Gray or Red color series (3fe or 3li, brownish gray from the Gray color series to 5dc or 5ch, grayish yellowish pink, in the Red color series). Reverse side of colony with no distinctive pigments (colorless, pale or grayish yellow or light olive gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments not produced in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment, or only trace of yellow pigment, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. cacaoi* subsp. *asoensis*, DQ026644, 99.5%; *S. rishiriensis*, EF178691, 99.3%; *S. novaecaesareae*, AB184357, 99.1%; *S. pseudovenezuelae*, AB184233, 99%.

Type strain: ATCC 12760, ATCC 23923, CBS 907.68, BCRC 13707, DSM 40263, NBRC 12877, JCM 4386, NRRL B-3172, NRRL-ISP 5263, RIA 1186, VKM Ac-1703.

Sequence accession no. (16S rRNA gene): DQ442508.

251. **Streptomyces humiferus** Goodfellow, Williams and Alderson 1986a, 574^{VP} (Effective publication: Goodfellow, Williams and Alderson 1986e, 63.) (*Actinopycnidium caeruleum* Krasil'nikov 1962, 250)

hu.mi'fer.us. L. n. *humus* ground; L. v. *fero* to bear; N.L. masc. adj. *humiferus* borne of the ground, i.e. soil-borne.

Spore chains are *Spirales*; the spore surface is smooth. Forms extensively branched substrate and aerial mycelium. The aerial spore mass is gray; the reverse is red-orange and the pigment is pH-sensitive; red-orange diffusible pigments which are also pH-sensitive are produced. Does not form melanin pigments. Allantoin, adenine, esculin, arbutin, elastin, gelatin, guanine, hypoxanthine, pectin, starch, testosterone, tyrosine, urea, and xanthine are degraded but chitin and lecithin are not. Hydrogen sulfide is produced and nitrate is reduced. L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, D-lactose, mannitol, D-mannose, melibiose, raffinose, L-rhamnose, trehalose, and D-xylose are used as sole carbon sources but adonitol, inulin, melezitose, sucrose, and xylitol are not. Grows on L-arginine, L-cysteine, L-histidine, L-phenylalanine, potassium nitrate, L-threonine, and L-valine but not on DL-amino-n-butyric acid, L-hydroxyproline, L-methionine, or L-serine as sole nitrogen sources. Grows at 10–37°C, but not at 4 or 45°C. Tolerant to phenol (0.01%, w/v) and sodium chloride (10%, w/v) but not to sodium azide (0.01%, w/v). Resistant to rifampin. Antimicrobial activity shown against *Streptomyces murinus* ISP 5091 but not towards *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046^T, and *Saccharomyces cerevisiae* CBS 1171^T. The peptidoglycan contains LL-A_2pm as the major diamino acid.

Type strain shows the highest sequence similarity to: *S. coelescens*, AF503496, 100%; *S. violaceolatus* AF503497, 100%; *S. violaceoruber*, AF503492, 100%; *S. tricolor*, AB184687, 99.8%; *S. anthocyanicus*, AB184631, 99.8%; *S. rubrogriseus*, AB184681, 99.7%; *S. tendae*, D63873, 99.5%; *S. lienomycini*, AJ781353, 99.5%; *S. violaceorubidus*, AJ781374, 99.3%; *S. coelicoflavus*, AB184650, 99.3%.

Source: not known.

DNA G+C content (mol%): 70.4.

Type strain: AS 4.1070, ATCC 15719, ATCC 15812, DSM 43030, IFM 1139, NBRC 12244, IMET 43409, JCM 3037, KCC A-0037, KCTC 9116, NCIMB 10164, RIA 729, VKM Ac-644.

Sequence accession no. (16S rRNA gene): AF503491.

Further comments: the genus *Actinopycnidium* Krasil'nikov 1962 is reduced to synonymy with *Streptomyces* Waksman and Henrici 1943. For *Actinopycnidium caeruleum* Krasil'nikov 1962, it is necessary to substitute a new specific epithet, because there is a senior homonym, *Streptomyces caeruleus* (Baldacci 1944) Pridham et al. 1958, cited on the Approved Lists of Bacterial Names (Rules 34a and 41a of the *Bacteriological Code* (1990 Revision).

252. **Streptomyces hydrogenans** Lindner, Junk, Nesemann and Schmidt-Thomé 1958, 117^{AL}

hy.dro'gen.ans. Gr. n. *hudôr* water; Gr. v. *gennaô* to produce; N.L. part. adj. *hydrogenans* water producing.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar; White or Yellow color series on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs in the Gray color series are d, light gray, and 5fe, light grayish reddish brown. Nearest matching tab in the Yellow color series is 2ba, pale yellow. Reverse side of colony with no distinctive pigments (pale or grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and rhamnose are utilized for growth. No growth or only traces of growth with iso-inositol, D-mannitol, D-fructose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. violascens*, AY999737, 100%; *S. odorifer*, Z76682, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. canescens*, AB184117, 100%; *S. sampsonii*, D63871, 99.8%; *S. koyangensis*, AY079156, 99.7%.

Source: not known.
DNA G+C content (mol%): not known.
Type strain: ATCC 19631, CBS 776.72, BCRC 11855, DSM 40586, HAMBI 405, NBRC 13475, JCM 4771, NRRL B-12091, NRRL-ISP 5586, RIA 1436, VKM Ac-1919.
Sequence accession no. (16S rRNA gene): AB184868.

253a. **Streptomyces hygroscopicus subsp. hygroscopius** (Jensen 1931) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 953[AL] ("*Actinomyces hygroscopicus*" Jensen 1931, 357)

hy.gro.sco′pi.cus. Gr. adj. *hugros* moist; Gr. n. *skopos* one that watches, watcher; N.L. masc. adj. *hygroscopicus* detecting moisture, covered with moisture, hygroscopic.

Spore chains in Section *Spirales*; tight spirals in dense clusters. Spirals may coalesce as dark, moist masses of spores. Mature spore chains generally contain 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is warty; individual spores are poorly delineated. Moist, black, liquefied (hygroscopic) areas are found in the aerial mycelium in 14–21 d. These are especially common on oatmeal agar and salts-starch agar.

Color of colony: aerial mass color in the Gray color series (3fe, 3li or 5ih, brownish gray; or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Dark or medium gray areas are also reported on oatmeal agar and salts-starch agar, and moist black (hygroscopic) areas may be seen on older cultures. Reverse side of colony with no distinctive pigments (colorless to grayish yellow, pale yellow or light olive brown or gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, except that dark discoloration may be seen beneath hygroscopic areas.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Good growth is reported on carbon-free control medium as well as on L-arabinose, D-xylose, and iso-inositol, so that utilization of these carbon sources is doubtful. Sucrose and raffinose are probably not utilized.

Type strain shows the highest sequence similarity to: *S. endus*, AY999911, 100%; *S. sporocinereus*, AB249933, 100%; *S. demainii*, DQ334782, 99.9%; *S. yogyakartensis*, AB249942, 99.5%; *S. violaceusniger*, AJ391823, 99.5%; *S. albiflaviniger*, AJ391812, 99.3%.

Sequence accession no. (16S rRNA gene): AB184428.

253b. **Streptomyces hygroscopicus subsp. angustmyceticus** Yüntsen, Ohkuma, Ishii and Yonehara 1956, 200[AL]

an.gust.my.ce′ti.cus. L. adj. *angustus* narrow; Gr. n. *mukês* fungus; N.L. adj. *myceticus* fungus-like; N.L. masc. adj. *angustmyceticus* like a narrow fungus, but referring to the narrow spectrum of anti-bacterial activity of the organism, hence angustmycin.

Excellent growth on Czapek's solution agar; hygroscopic; NaCl tolerance >10%, but <13%. Produces angustmycin A, angustmycin B (adenine) and angustmycin C-anti-mycobacterial antibiotics; exhibits anti-fungal activity; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. ehimensis*, AY999834, 99.8%; *S. abikoensis*, AB184537, 99.7%; *S. sapporonensis*, AB184508, 99.5%; *S. lilacinus*, AB184819, 99.4%; *S. luteireticuli*, AB249969, 99.1%; *S. varsoviensis*, DQ026653, 99.1%; *S. thioluteus*, AB184753, 99%; *S. morookaense*, AJ781349, 99%; *S. mobaraensis*, DQ442528, 99%.
Source: not known.
DNA G+C content (mol%): not known.
Type strain: ATCC 15484, DSM 41683, NBRC 3934, JCM 4053, KCTC 1089, NRRL B-2347, NRRL B-3306.
Sequence accession no. (16S rRNA gene): DQ442509.

253c. **Streptomyces hygroscopicus subsp. decoyicus** Vavra, Dietz, Churchill, Siminoff and Koepsell 1959, 427[AL]

de.co′yi.cus. N.L. n. *decoyininum* decoyinine, name of an antibiotic; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *decoyicus* intended to mean possessing decoyinine.

Excellent growth on Czapek's solution agar; hygroscopic; NaCl tolerance >10%, but <13%. Produces angustmycins A and C; exhibits anti-fungal activity; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. caniferus*, AB184640, 99.6%; *S. libani* subsp. *rufus*, AJ781351, 99.6%; *S. sioyaensis*, DQ026654, 99.6%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.6%; *S. platensis*, AB045882, 99.4%; *S. monomycini*, DQ445790, 99.4%; *S. erumpens*, AJ621603, 99.2%; *S. libani* subsp. *libani*, AB184414, 99.2%; *S. tubercidicus*, AJ621612, 99.2%; *S. nigrescens*, DQ442530, 99.2%; *S. lydicus*, Y15507, 99%.

253e. **Streptomyces hygroscopicus subsp. ossamyceticus** Schmitz, Jubinski, Hooper, Crook, Price and Lein 1965, 87[AL]

os.sa.my.ce′ti.cus. N.L. n. *ossamycinum* ossamycin, name of an antibiotic named for Mount Ossa of Greek mythology; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *ossamyceticus* belonging to ossamycin.

Petri dish cultures grown at 28°C on inorganic salts-starch agar show following morphology. Vegetative mycelium: branched, approx. 0.75–1 µm in diameter, no evidence of fragmentation. Aerial mycelium: branched, approx. 0.75–1 µm in diameter. Sporophore morphology: short side branches located along the main axial hyphae terminate in tight spiral spore chains of two to many turns; sporophores arranged singly, in pairs, or in clusters along the axial hyphae; no evidence of whorl formation. Conidia: catenulate, subglobose to elongated ovoid, most conidia ovoid measuring approx. 0.75 × 1–1.5 µm, smooth walls. For detailed cultural characteristics, see Schmitz et al. (1965). Produces ossamycin.

Type strain shows the highest sequence similarity to: *S. torulosus*, AJ781367, 100%; *S. neyagawaensis*, D63869, 99.4%; *S. ipomoeae*, AB184857, 99.3%.

Source: isolated from a soil sample collected in South America.

DNA G+C content (mol%): not known.

Type strain: ATCC 15420, CIP 106834, DSM 40824, NBRC 13983, JCM 4965, NRRL B-3822.

Sequence accession no. (16S rRNA gene): AB184560.

254. **Streptomyces iakyrus** de Querioz and Albert 1962, 33[AL]

i.a.ky′rus. N.L. masc. adj. *iakryus* [from Amazonian oral aboriginal language (Nheêngatû) adj. *iakryus*] green, referring to the color of the vegetative mycelium and diffusible pigment on some media.

Spore chains in Section *Spirales*. Mature spore chains are generally long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray or Red color series on oatmeal agar and salts-starch agar; nearest matching color tab in the Gray color series is 5fe, light grayish reddish brown, and in the Red color series 5dc, grayish yellowish pink. These colors as well as white aerial mycelium are reported for yeast-malt agar and glycerol-asparagine agar (a variety of colors reported on yeast-malt agar also includes tabs from the Yellow color series and the Blue color series). Reverse side of colony is greenish yellow, olive gray, olive, or olive brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but only slightly or not at all on tyrosine agar. Yellow to yellow-green pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. violaceochromogenes*, AY999867, 99.5%; *S. longispororuber*, AB184440, 99.4%; *S. coerulescens*, AY999720, 99.3%; *S. collinus*, AB184123, 99.3%; *S. coeruleorubidus*, AY999719, 99.3%; *S. bellus*, AB184849, 99.3%; *S. speibonae*, AF452714, 99.3%; *S. lomondensis*, AB184673, 99.1%; *S. purpurascens*, AJ399486, 99.1%; *S. viridodiastaticus*, AY999852, 99.1%; *S. griseorubens*, AB184139, 99%; *S. albogriseolus*, AJ494865, 99%; *S. lusitanus*, AB184424, 99%; *S. griseoflavus*, AJ781322, 99%.

255. **Streptomyces indiaensis** (Gupta 1965a) Kudo and Seino 1987, 243[VP] ("*Streptosporangium indianense*" Gupta 1965a)

in.di.a.en′sis. L. n. *india* India; L. suff. *ensis* indicating origin; N.L. masc. adj. *indiaensis* of or belonging to India.

Spore chains are *Spirales*; spore surface is smooth. Branching substrate and aerial mycelia are formed. Pseudosporangia on aerial mycelia are 2–10 µm in diameter and globular to oval or irregular. Aerial mass color is gray to grayish-violet; the reverse side of the colony is red to violet. Reverse color is changed from violet to red by addition of 0.05 M NaOH. Soluble pigment is red or violet. Melanoid pigment is formed in peptone-yeast extract iron agar, but not in tyrosine agar or tryptone-yeast extract agar. L-Arabinose, D-fructose, D-glucose, iso-inositol, lactose, D-mannitol, sucrose, and D-xylose are utilized for growth, but raffinose, L-rhamnose and salicin are not.

Type strain shows the highest sequence similarity to: *S. purpurascens*, AJ399486, 99.6%; *S. massasporeus*, AB184152, 99.6%; *S. thermocarboxydus*, U94490, 99.3%; *S. hawaiiensis*, AB184143, 99.3%; *S. coerulescens*, AY999720, 99.2%; *S. bellus*, AB184849, 99.2%; *S. lomondensis*, AB184673, 99.1%; *S. coeruleorubidus*, AY999719, 99%; *S. lusitanus*, AB184424, 99%; *S. arenae*, AB249977, 99%.

Source: not known.

DNA G+C content (mol%): 73.7.

Type strain: ATCC 33330, CBS 560.75, DSM 43803, NBRC 13964, JCM 3053, KCC A-0053, KCTC 9489, NCIB (now NCIMB) 9794.

Sequence accession no. (16S rRNA gene): AB184553.

256. **Streptomyces indigoferus** Shinobu and Kawato 1960, 49[AL]

in.di.go.fer′us. N.L. n. *indigo* (from Fr. n. *indigo*, derived from L. n. *indicum*, indigo) the dye indigo; L. suff. *-fer -fera -ferum* (from L. v. *fero*, to bear), bearing; N.L. masc. adj. indigoferus (*sic*) bearing (producing) indigo and referring to production of blue to green diffusible pigments on chemically defined media.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately long with 10–50, or sometimes more than 50, spores per chain. Aerial mycelium is poorly developed on all ISP media and is obscured by extensive coremia formation on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color often cannot be determined because of inadequate aerial growth on oatmeal agar or because of extensive coremia formation on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. When adequate aerial mycelium is formed, it is in the Gray color series on yeast-malt agar and oatmeal agar. Aerial mass color in the Gray color series was also found on glycerol-asparagine agar and soil extract agar by one observer. Reverse side of colony: substrate mycelium is usually nearly colorless. grayish yellow or dark brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. A transient blue to red pigment (depending on pH) may also be found in the mycelium on these media. This pigment changes from blue or colorless to red with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but are not formed in tyrosine agar. Pigments other than melanoids are not found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and L-arabinose are utilized for growth. Utilization of xylose is doubtful. No growth or only traces of growth on sucrose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. herbaricolor*, AB184801, 100%; *S. aburaviensis*, AY999779, 99.6%; *S. purpureus*, AJ781324, 99.6%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.5%; *S. purpeofuscus*, AJ781364, 99.2%; *S. xanthocidicus*, AY999858, 99.2%. Type strain shows the highest sequence similarity to following *Kitasatospora* species: *Kitasatospora kifunensis*, AB022874, 99.3%; *Kitasatospora nipponensis*, AY442263, 99%; *Kitasatospora gansuensis*, AY442265, 99%.

Sequence accession no. (16S rRNA gene): AB184214.

257. **Streptomyces indonesiensis** Sembiring, Ward and Goodfellow 2001, 1619[VP] (Effective publication: Sembiring, Ward and Goodfellow2000, 365.)

in.do.ne.si.en′sis. N.L. masc. adj. *indonesiensis* of or pertaining to Indonesia.

Spore chains are *Spirales*; spore surface is rugose. On oatmeal agar, the spore mass is gray, the substrate mycelium grayish-yellow and the diffusible pigment yellow. Melanin pigments are not produced. The strain degrades pectin but not adenine.

Type strain shows the highest sequence similarity to: *S. asiaticus*, AB249947, 99.1%; *S. cangkringensis*, AJ391831, 99.7%; *S. rhizosphaericus*, AB249941, 99.7%; *S. griseinger*, AJ391818, 99.4%. Type strain shows DNA–DNA similarity to: *S. albiflaviniger* NRRL B-1356[T] 98.3%; *S. geldanamycinus* NRRL 3602[T], 98.2%; *S. griseiniger* NRRL B1865[T], 98.7%; *S. rhizosphaericus* DSM 41760[T], 98.3%; *S. asiaticus* DSM 41761[T], 99.1%; *S. javensis* DSM 41764[T], 98.2%; *S. yogyakartensis* DSM 41766[T], 98.1%; *S. cangkringensis* DSM 41769[T], 99.2%.

Source: isolated from the rhizosphere of the tropical legume *Paraserianthes falcataria*.

DNA G+C content (mol%): not known.

Type strain: A4R2, DSM 41759, JCM 11445, NBRC 100776, NCIMB 13673.

Sequence accession no. (16S rRNA gene): DQ334783.

258. **Streptomyces intermedius** (Krüger 1904) Waksman *in* Waksman and Lechevalier 1953, 116[AL] ("*Oospora intermedia*" Krüger 1904, 289; "*Actinomyces intermedius*" Wollenweber 1920, 13)

in.ter.me′di.us. L. masc. adj. *intermedius* intermediate.

Spore chains in Section *Rectiflexibiles*. Flexuous chains of 10–50 spores occur as tufts or clusters on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although production of sporulating aerial mycelium is not uniformly good in different laboratories with this strain. Spore surface is smooth.

Color of colony: sporulating aerial mycelium is usually inadequate for determination of aerial mass color. When aerial mycelium is formed, it is in the Yellow color series (1bc, pale yellow-green; 2ba, pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (aerial mycelium is described as light green or light gray in the descriptions of Krasil'nikov, 1941, and Waksman, 1953). Reverse side of colony with no distinctive pigments (colorless to pale grayish yellow or light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only traces of growth with iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. gougerotii*, AB184742, 99.8%; *S. diastaticus* subsp. *diastaticus*, AB184785, 99.8%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 99.8%; *S. koyangensis*, AY079156, 99.1%; *S. misionensis*, EF178678, 99%; *S. phaeoluteichromatogenes*, AJ391814, 99%; *S. aureoverticillatus*, AY999774, 99%; *S. matensis*, AB184221, 99%.

Source: not known.

Type strain: ATCC 3329, ICMP 12540, AS 4.1467, ATCC 25461, CBS 101.21, CBS 694.69, BCRC 13706, DSM 40372,

ICMP 12540, NBRC 13049, IMET 41384, JCM 4197, JCM 4483, LMG 19304, NRRL B-1327, NRRL B-2670, NRRL-ISP 5372, RIA 1241.

Sequence accession no. (16S rRNA gene): AB184277.

259. **Streptomyces inusitatus** Hasegawa, Yamano and Yoneda 1978, 409[AL]

i.nu.si.ta′tus. L. masc. adj. *inusitatus* unusual.

Spore-bearing hyphae are simply branched and possess open or closed coils of spores. Spores (0.5–0.7 × 0.9–1.4 μm) are ellipsoidal to cylindrical, have smooth spore surfaces, and are arranged in coiled chains. The color of the aerial mycelium is blue-gray to gray-blue on Czapek agar, glucose-asparagine agar, yeast extract-malt extract agar, inorganic salts-starch agar, and tyrosine agar. Reverse side of colony with no distinctive pigments on either chemically defined or organic media. Color in medium: no pigment or only a trace of ivory color is formed on oatmeal agar. Starch is hydrolyzed, gelatin is weakly liquefied, and milk is peptonized. Carbon sources such as maltose, lactose, glycerol, starch, and sodium citrate are utilized for growth. Poor growth is obtained with D-galactose and D-glucose. L-A_2pm acid, glycine, aspartic acid, alanine, leucine, and glutamic acid, but not arabinose and galactose, are contained in cell-wall preparations. Produces oxamicetin.

Type strain shows the highest sequence similarity to: *S. amakusaensis*, AY999781, 99.8%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 33341, CBS 196.78, DSM 41441, NBRC 13601, JCM 4988, NRRL B-16929.

Sequence accession no. (16S rRNA gene): AB184445.

260. **Streptomyces ipomoeae** (Person and Martin 1940) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 958[AL] ["*Actinomyces ipomoea*" (*sic*) Person and Martin 1940, 923; "*Streptomyces ipomoea*" (*sic*) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 958]

i.po.mo.e′a.e. N.L. n. *Ipomoea* generic name of the sweet potato; N.L. gen. n. *ipomoeae* of *Ipomoea*, referring to the source of the organism.

Spore chains in Section *Spirales*. Spore chains are usually short with 3–10 spores per chain and may give rise to hooks, loops, incomplete spirals, or spirals of only 1 or 2 turns. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but typical aerial mycelium is usually not found on glycerol-asparagine agar. Spore surface is smooth; wrinkles or folds may be present.

Color of colony: aerial mass color in the Blue color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is pale yellow or grayish yellow on yeast-malt agar and glycerol-asparagine agar; yellow may be modified by blue (very pale blue or pale green) on reverse side of mature growth on oatmeal agar and salts-starch agar. This pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Traces of yellow or green pigment may or may not be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. hygroscopicus* subsp. *ossamyceticus*, AB184560, 99.3%; *S. torulosus*, AJ781367, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: 9820, ATCC 25462, CBS 695.69, DSM 40383, ICMP 12541, NBRC 13050, KCC S-0484, NRRL-ISP 5383, RIA 1242.

Sequence accession no. (16S rRNA gene): AB184857.

261. **Streptomyces janthinus** (Artamonova and Krasil'nikov 1960) Pridham 1970, 19[AL] ("*Actinomyces janthinus*" Artamonova and Krasil'nikov *in* Rautenshtein 1960, 334)

jan′thi.nus. L. masc. adj. *janthinus* violet-colored, referring to color of vegetative mycelium and diffusible pigment.

Spore chains in Section *Spirales*. Spore chains are moderately long with 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red or White color series on yeast-malt agar and salts-starch agar; White color series on oatmeal agar, and White or Gray color series on glycerol-asparagine agar. The nearest color tabs in the Red color series are 5dc, 5ca, 5cb, and 6ec (all grayish yellowish pink). Reverse side of colony with no distinctive pigments (colorless to grayed yellow or pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. Yellow pigment is found in the medium in salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. roseoviolaceus*, AJ399484, 100%; *S. violaceus*, AB184315, 100%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 100%; *S. luteogriseus*, AB184379, 99.5%; *S. lomondensis*, AB184673, 99.3%; *S. hawaiiensis*, AB184143, 99.3%; *S. flavoviridis*, AB184842, 99.3%; *S. pilosus*, AB184161, 99.2%; *S. arenae*, AB249977, 99.2%; *S. africanus*, AY208912, 99.2%; *S. tuirus*, AB184690, 99.2%; *S. bellus*, AB184849, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. massasporeus*, AB184152, 99%; *S. afghaniensis*, AJ399483, 99%; *S. levis*, AB184670, 99%; *S. coerulescens*, AY999720, 99%; *S. parvulus*, AB184326, 99%; *S. coeruleorubidus*, AY999719, 99%.

262. **Streptomyces javensis** Sembiring, Ward and Goodfellow 2001, 1619[VP] (Sembiring, Ward and Goodfellow 2000, 365)

ja.ven′sis. N.L. masc. adj. *javensis* of or pertaining to Java, Indonesia.

Spore chains are *Spirales*; spore surface is rugose. On oatmeal agar, the spore mass is gray, the substrate mycelium grayish-yellow and the diffusible pigment yellow. Melanin pigments are not produced. The organism degrades xylan and does not grow at 45°C.

Type strain shows the highest sequence similarity to: *S. yogyakartensis*, AB249942, 99.2%; *S. violaceusniger*, AJ391823, 99.1%. Type strain shows DNA–DNA similarity to: *S. albiflaviniger* NRRL B-1356^T, 98.9%; *S. geldanamycinus* NRRL 3602^T, 98.9%; *S. griseiniger* NRRL B-1865^T, 98.6%; *S. rhizosphaericus* DSM 41760^T, 98.3%; *S. asiaticus* DSM 41761^T, 98.2%; *S. indonesiensis* DSM 41759^T, 98.6%; *S. yogyakartensis* DSM 41766^T, 98.6%; *S. cangkringensis* DSM 41769^T, 98.4%.

Source: isolated from non-rhizosphere soil adjacent to a stand of the tropical legume *Paraserianthes falcataria*.

DNA G+C content (mol%): not known.

Type strain: B22P3, DSM 41764, JCM 11446, NBRC 100777, NCIMB 13679.

S*equence accession no. (16S rRNA gene):* AJ391833.

263. **Streptomyces jietaisiensis** He, Li, Huang, Wang, Liu, Lanoot, Vancanneyt and Swings 2005, 1943^{VP}

jie.tai.si.en′sis. N.L. masc. adj. *jietaisiensis* of or pertaining to Jietaisi, a place in a suburb of Beijing, where the type strain was isolated.

Spore chains with 10–20 cylindrical spores are *Rectiflexibiles*. The spore surface is smooth. Diffusible pigments are not produced, nor are melanin pigments formed on peptone-yeast extract-iron agar, or tyrosine agars. Adonitol, cellobiose, dextrin, D-galactose, D-glucose, inulin, glycogen, maltose, D-mannitol, D-mannose, melezitose, salicin, trehalose, and D-xylose (all at 1%, w/v), and L-alanine, L-arginine, L-aspartic acid, L-cysteine, L-glutamic acid, L-histidine, L-isoleucine, L-phenylalanine, sodium oxalate, sodium pyruvate, L-threonine, and L-valine (all at 0.1%, w/v) are used as sole carbon sources for energy and growth, but not glycerol, glycine, and xylitol (all at 1%, w/v) or DL-aminobutyric acid (at 0.1%, w/v). L-Alanine, L-arginine, L-aspartic acid, L-glutamic acid, and L-phenylalanine (all at 0.1%, w/v) are metabolized as sole carbon and nitrogen sources, but not L-isoleucine (at 0.1%, w/v). Growth occurs between 10 and 40°C, and between pH 5.0 and 10.0, but not at pH 4.0 or 11.0 or in the presence of streptomycin (10 μg/ml) or novobiocin (5 μg/ml). Cell-wall type I, phospholipid type II, and menaquinone MK-9(H_6,H_8,H_4). The fatty acid profile is composed of $C_{15:0}$ anteiso (35.7%), $C_{17:0}$ anteiso (18.9%), $C_{16:0}$ iso (14.8%), $C_{17:1}$ anteiso ω9*c* (8.1%), $C_{16:0}$ (6.2%), $C_{16:1}$ iso (4.5%), $C_{15:0}$ iso (4.3%), $C_{16:1}$ ω7*c* (2.33%), $C_{17:1}$ iso ω9*c* (1.8%), $C_{17:0}$ iso (1.7%), and $C_{14:0}$ iso (1.7%).

Type strain shows the highest sequence similarity to: *S. griseoaurantiacus*, AB184676, 99.7%. Type strain shows DNA–DNA similarity to: *S. griseoaurantiacus* DSM 40430^T, 48.8%.

Source: not known.

DNA G+C content (mol%): 72.3.

Type strain: FXJ46, AS 4.1859, JCM 12279.

Sequence accession no. (16S rRNA gene): AY314783.

264. **Streptomyces kanamyceticus** Okami and Umezawa *in* Umezawa, Ueda, Maeda, Yagishita, Kondō, Okami, Utahara, Ōsato, Nitta and Takeuchi 1957, 183^{AL}

ka.na.my.ce′ti.cus. N.L. n. *kanamycinum* kanamycin, name of an antibiotic; L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *kanamyceticus* belonging to kanamycin.

Spore chains in Section *Rectiflexibiles*. Sporulating aerial mycelium is usually not abundant or may be absent on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although one observer reports long spore chains with 50 or more spores per chain on all of these media. Spore surface is smooth. Special morphological characteristics: terminal droplets showing wide variation in size are often found on aerial hyphae. These may contain coalesced masses of spores but they do not appear to be sporangia.

Color of colony: aerial mass color in the Yellow or White color series when sporulating aerial mycelium is present on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs from the Yellow color series are 1½fb, light yellow; 2db, pale yellow; and 1db, pale yellow-green. Reverse side of colony with no distinctive pigments (colorless to pale yellow or grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, raffinose, and D-mannitol are utilized for growth. No growth or only traces of growth with iso-inositol, rhamnose, or sucrose.

Type strain shows the highest sequence similarity to: *S. aureus*, AB249976, 99.5%; *S. durmitorensis*, DQ067287, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1441, ATCC 12853, CBS 715.72, BCRC 11515, DSM 40500, NBRC 13414, JCM 4433, JCM 4775, KCTC 9225, LMG 5976, LMG 19351, NCIMB 9343, NRRL B-2535, NRRL-ISP 5500, RIA 1375, RIA 690, VKM Ac-837.

Sequence accession no. (16S rRNA gene): DQ442511.

265. **Streptomyces kashmirensis** (*sic*) (Gupta and Chopra 1963b) Witt and Stackebrandt 1991, 456^{VP} (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces kashmirensis*" Gupta and Chopra 1963a, 112; *Streptoverticillium kashmirense* Locci, Baldacci and Petrolini Baldan 1969, 59)

kash.mir.en′sis. N.L. masc. adj. *kashimirensis* (*sic*) of or pertaining to Kashmir.

Spore chains in Section *Verticillati*, umbellate monoverticillate (biverticillate). Mature spore chains are generally short with 3 to 10 or more spores per chain. This morphology is usually seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although sporulation is not always good on these media. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5cb or 5dc, grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When aerial mycelium is poorly developed, the surface color may appear to be in the Gray (d, light gray, or 2dc, yellowish gray) or White color series. The original description of Gupta and Chopra (1963b) reports blue aerial mycelium on Emmerson's medium. Reverse side of colony with distinctive red pigments (grayish red or moderate reddish brown on yeast-malt agar and oatmeal agar; light brown to dark brown on salts-starch agar and glycerol-asparagine agar). The reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth in 4 d; reaction may be weak on tyrosine agar. Yellow to orange or reddish pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose and iso-inositol are utilized for growth. Only traces of growth are seen with L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose.

For sequence similarity, see type strain of *Streptomyces lilacinus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27439, CBS 665.72, DSM 40336, NBRC 13906, JCM 4776, NRRL B-3103, NRRL-ISP 5336, RIA 1325, VKM Ac-885.

Sequence accession no. (16S rRNA gene): AB184546.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces kashmirensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces kashmirensis*" Gupta and Chopra 1963b).

According to Hatano et al. (2003), *Streptomyces kashmirensis* (sic) (Gupta and Chopra 1963b) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces lilacinus* (Nakazawa et al. 1956) Witt and Stackebrandt 1991.

266. **Streptomyces kasugaensis** Hamada, Kinoshita, Hattori, Yoshida, Okami, Higashide, Sakata and Hori 1995b, 879[VP] (Effective publication: Hamada, Kinoshita, Hattori, Yoshida, Okami, Higashide, Sakata and Hori 1995a, 35.)

ka.su.ga.en′sis. N.L. masc. adj. *kasugaensis* of or pertaining to Kasuga, Japan.

Substrate mycelia are well-branched. Aerial mycelia form complete spiral chains of spores. Mature spore chains consist of 10 or more spores. The spores are oval (0.6–0.7 × 0.6–0.8 μm) and the spore surface is smooth. The spores are not motile. No synnemata, sclerotia, or sporangia are observed. Aerial mycelia are light olive gray to light brownish gray, and vegetative mycelia are colorless to pale yellowish brown on various media. Yellow to brownish soluble pigments are produced on various media. Melanoid pigments are not produced on peptone-yeast extract iron agar (ISP 6), tyrosine agar (ISP 7), or in tryptone-yeast extract broth (ISP 1). Starch is not hydrolyzed, gelatin is liquefied, milk is peptonized and coagulated, and nitrate is reduced. D-Glucose, D-fructose, raffinose, and *myo*-inositol are utilized for growth, but L-arabinose, D-xylose, rhamnose, sucrose, and D-mannitol are not utilized. Permissive temperature range for growth is 20–37°C. Whole-cell hydrolysates contain LL-A_2pm, but no detectable arabinose, galactose, or *meso*-A_2pm. Phospholipid pattern type is PII. Mycolic acids are absent. Major menaquinones are MK-9(H_6), MK-9(H_8), and MK-9(H_4). Major components of cellular fatty acids are $C_{15:0}$ anteiso, $C_{16:0}$, $C_{17:0}$ anteiso, and $C_{16:0}$ iso.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): 70.4–70.9.

Type strain: M338-M1, ATCC 15714, BCRC 12349, DSM 40819, NBRC 13851, JCM 4208, KCTC 1078, KCTC 2113, NCIMB 12239, NCIMB 12718.

Sequence accession no. (16S rRNA gene): AB024441.

267. **Streptomyces katrae** Gupta and Chopra 1963b, 1[AL]

kat′ra.e. N.L. gen. n. *katrae* of Katra, named for Katra, Jammu Province, India, the source of the soil from which the organism was isolated.

Spore chains in Section *Retinaculiaperti*. Long spore chains with terminal primitive spirals, hooks, or loops of wide diameter. Some well-defined spirals are also seen. Mature spore chains are long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5dc, 5cb or 4ca, grayish yellowish pink; 5ca, light yellowish pink; or 3ca, pale orange-yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (yellowish brown to olive brown on yeast-malt agar; grayish yellow to yellowish brown on salts-starch agar, oatmeal agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, and sucrose are utilized for growth. No growth or only traces of growth with iso-inositol, D-mannitol, rhamnose, or raffinose.

Type strain shows the highest sequence similarity to: *S. polychromogenes*, AB184292, 99.5%; *S. racemochromogenes*, DQ026656, 99.5%; *S. flavotricini*, AB184132, 99.2%.

Source: isolated from soil from Katra, Jammu Province, India.

DNA G+C content (mol%): not known.

Type strain: ATCC 27440, CBS 748.72, DSM 40550, NBRC 13447, IMET 43361, JCM 4777, NRRL B-3093, NRRL-ISP 5550, RIA 1408, RIA 794, VKM Ac-1220.

Sequence accession no. (16S rRNA gene): AB184409.

268. **Streptomyces kentuckensis** (Barr and Carman 1956) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces kentuckensis*"

Barr and Carman 1956; "*Verticillomyces kentuckensis*" Shinobu 1965; *Streptoverticillium kentuckense* Baldacci, Farina and Locci 1966, 170)

ken.tuck.en′sis. N.L. masc. adj. *kentuckensis* of or pertaining to Kentucky.

Spore chains in Umbellate Monoverticillate (=*Streptomyces* Section *Verticillati*, biverticillate). Mature spore chains moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar; Red or White color series on glycerol-asparagine agar. Reverse side of colony with no distinct pigments (grayed yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar to brown on yeast-malt agar).

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, iso-inositol, and fructose are utilized for growth; utilization of D-xylose is doubtful. No growth or only trace of growth on L-arabinose, sucrose, D-mannitol, rhamnose, and raffinose.

For sequence similarity, see type strain of *Streptomyces netropsis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 12691, ATCC 23926, CBS 910.68, DSM 40052, HAMBI 52, NBRC 12880, IPV 940, IPV 1780, IPV1958, JCM 4153, JCM 4647, KCC S-153, LMG 5977, NRRL B-1831, NRRL-ISP 5052, RIA 1114.

Sequence accession no. (16S rRNA gene): AB184215.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces kentuckensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces kentuckensis*" Barr and Carman 1956).

According to Labeda (1996) and to Hatano et al. (2003), *Streptomyces kentuckensis* (Barr and Carman 1956) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces netropsis* (Finlay et al. 1951) Witt and Stackebrandt 1991.

269. **Streptomyces kishiwadensis** (Shinobu and Kayamura 1964) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces kishiwadensis*" Shinobu and Kayamura 1964; "*Verticillomyces kishiwadenis*" Shinobu 1965; *Streptoverticillium kishiwadense* Locci, Baldacci and Petrolini Baldan 1969, 59)

ki.shi.wad.en′sis. N.L. masc. adj. *kishiwadensis* of or belonging to Kishiwada (named after the place of origin, Kishiwada City, Japan).

Spore chains in Section *Verticillati*. Both monoverticillate and umbellate monoverticillate (biverticillate) sporophores are found. Mature sporophores are usually umbellate monoverticillate. Spore chains are short with 3–10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5ca, light yellowish pink to 5cb, grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; white to pale yellow or pale orange-yellow (3ca) aerial mass color may also be seen on these media. Reverse side of colony with no distinctive pigments (pale grayish yellow to orange-yellow or yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but only weakly or not at all in tyrosine agar. No pigment found in medium with yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, iso-inositol, D-fructose, and sucrose are utilized for growth. Utilization of D-xylose is doubtful and there is no growth or only traces of growth with L-arabinose, D-mannitol, rhamnose, and raffinose.

For sequence similarity, see type strain of *Streptomyces mashuensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25464, CBS 697.69, DSM 40397, NBRC 13052, JCM 4486, NRRL B-12326, NRRL-ISP 5397, RIA 1244, VKM Ac-931.

Sequence accession no. (16S rRNA gene): AB184858.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces kishiwadensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces kishiwadensis*" Shinobu and Kayamura 1964).

According to Hatano et al. (2003), *Streptomyces kishiwadensis* (Shinobu and Kayamura 1964) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces mashuensis* (Sawazaki et al. 1955) Witt and Stackebrandt 1991.

270. **Streptomyces koyangensis** Lee, Lee, Jung and Hwang 2005, 261[VP]

ko.yang.en′sis. N.L. masc. adj. *koyangensis* of or pertaining to Koyang, Republic of Korea, the geographical origin of the type strain.

Spore chains containing 10 or more spores per chain are *Rectiflexibiles*. Spores are spherical (1.2 m in diameter) with a smooth surface. The spore mass is white to gray and the reverse sides of colonies are brown on most agar media. Grows well on yeast extract-malt extract (ISP 2), oatmeal agar (ISP 3), inorganic salts-starch agar (ISP 4), peptone-yeast extract-iron agar (ISP 6), and tyrosine agar (ISP 7). Does not grow well on ISP 5 medium. Aerial mycelia are abundant on most of these media. The color of substrate mycelium is pale brown to dark brown. Production of spores on ISP 4 is prolific. Melanin pigments are produced on ISP 6 and ISP 7. Degrades casein, elastin, esculin, gelatin, starch, tyrosine, and xanthine, but not cellulose. As sole carbon sources, utilizes L-arabinose, D-fructose, mannitol, and xylose for growth, but not adon-

itol, dextran, *myo*-inositol, melezitose, melibiose, raffinose, L-rhamnose, sucrose, or xylitol. As nitrogen sources, utilizes L-cysteine, L-histidine, L-phenylalanine, and L-valine. It cannot utilize DL-α-amino-n-butyric acid or L-hydroxyproline. Pectin hydrolysis, nitrate reduction, and H_2S production are positive, whereas lecithinase, lipolysis, and hippurate hydrolysis are negative. Grows in the presence of 4, 7, and 10% sodium chloride, but not in 13%. It grows in 0.02% NaN_3 and 0.001% thallous acetate, but not in 0.1% phenol or 0.001% potassium tellurite. Whole-cell hydrolysates contain LL-A_2pm. The predominant cellular fatty acids are $C_{15:0}$ anteiso (16.54%), $C_{16:0}$ iso (28.77%), and $C_{16:0}$ (11.60%). In addition, $C_{17:0}$ anteiso (9.01%), $C_{14:0}$ iso (8.84%), $C_{15:0}$ iso (7.02%), $C_{17:0}$ cyclo (4.54%), $C_{17:1}$ anteiso (3.23%), $C_{17:0}$ iso (1.94%), $C_{14:0}$ (1.33%), $C_{16:1}$ iso (1.86%), and $C_{16:1}$ *cis*9 (2.57) are detected. Resistant to penicillin G, but sensitive to neomycin, rifampin, and oleandomycin. Produces 4-phenyl-3-buteonic acid, which inhibits the mycelial growth of several plant-pathogenic fungi, such as *Alternaria mali*, *Cladosporium cucumerinum*, *Colletotrichum gloeosporiuides*, *Colletotrichum orbiculare*, *Magnaporthe grisea*, and *Fusarium oxysporum* f. sp. *cucumerinum*.

Type strain shows the highest sequence similarity to: *S. odorifer*, Z76682, 99.7%; *S. hydrogenans*, AB184868, 99.7%; *S. daghestanicus*, DQ442497, 99.7%; *S. limosus*, AB184147, 99.7%; *S. albidoflavus*, AB184255, 99.7%; *S. felleus*, AB184129, 99.7%; *S. violascens*, AY999737, 99.7%; *S. griseus* subsp. *solvifaciens*, AB249915, 99.6%; *S. canescens*, AB184117, 99.6%; *S. champavatii*, DQ026642, 99.5%; *S. sampsonii*, D63871, 99.5%; *S. intermedius*, AB184277, 99.1%. Type strain shows DNA–DNA similarity to: *S. griseus* IFO 12875^T, 68.5%; *S. canescens* DSM 40001^T, 55.2%; *S. coelicolor* DSM 40233^T, 20.8%; *S. sampsonii* ATCC 25495^T, 64.0%; *S. odorifer* DSM 40347^T 34.4%; *S. limosus* DSM 40131^T, 66.8%; *S. felleus* DSM 40130^T, 25.6%; *S. somaliensis* DSM 40267, 57.5%.

Source: not known.

DNA G+C content (mol%): 67.8.

Type strain: VK-A60, KCCM 10555, NBRC 100598.

Sequence accession no. (16S rRNA gene): AY079156.

271. **Streptomyces kunmingensis** (Ruan, Lechevalier, Jiang and Lechevalier 1985) Goodfellow, Williams and Alderson 1986a, 574[VP] (Effective publication: Goodfellow, Williams and Alderson 1986d, 59.) (*Chainia kunmingensis* Ruan, Lechevalier, Jiang and Lechevalier 1985, 167)

kun.ming.en′sis. N.L. masc. adj. *kunmingensis* of or pertaining to Kunming, a province of South China.

Forms extensively branched substrate and aerial mycelium. Chains of conidia in loose spirals are occasionally borne on the aerial hyphae. Colonies are usually yellowish tan to dark orange yellow, depending on the medium, with or without yellowish white aerial mycelium. Produces sclerotia (5–25 μm) in and on the surface of agar media. Melanin pigments are not formed. Adenine, esculin, casein, hypoxanthine, starch, tyrosine, and xanthine are degraded, but gelatin and urea are not. Phosphatase and nitrate reductase are produced. L-Arabinose, D-mannitol, raffinose, L-rhamnose, and D-xylose are used as sole carbon sources, but *myo*-inositol and sucrose are not.

Acid is formed from L-arabinose, cellobiose, fructose, galactose, glucose, glycerol, *myo*-inositol, D-lactose, maltose, D-mannitol, mannose, melibiose, methyl α-D-glucoside, methyl α-D-xyloside, raffinose, L-rhamnose, salicin, sucrose, trehalose, and D-xylose but not from adonitol, dulcitol, *meso*-erythritol, or D-sorbitol. Grows at 10 and 37°C, but not at 42°C. The wall peptidoglycan contains LL-A_2pm as the major diamino acid. The organism has a type II phospholipid pattern (*sensu* Lechevalier et al., 1977).

Type strain shows no sequence similarity over 99%.

Source: isolated from soil at Dagyanlow's Lake in Kunming, Peoples' Republic of China.

DNA G+C content (mol%): 71.3.

Type strain: 80-3024, ATCC 35682, DSM 41681, NBRC 14463, JCM 7473, NRRL B-16240, VKM Ac-895.

Sequence accession no. (16S rRNA gene): DQ442513.

272. **Streptomyces kurssanovii** (Preobrazhenskaya, Kudrina, Ryabova and Blinov *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 69[AL] ("*Actinomyces kurssanovii*" Preobrazhenskaya, Kudrina, Ryabova and Blinov *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 156)

kurs.sa.nov′i.i. N.L. gen. masc. n. *kurssanovii* of Kursanov, possibly named after L.I. Kursanov, a Russian microbiologist.

Spore chains in Section *Retinaculiaperti*. Spirals are not observed on ISP media. Hooks and loops in the short spore chains are of small diameter and therefore are not truly representative of *Retinaculiaperti* morphology. The original description (Preobrazhenskaya and Ryabova, 1957) characterizes this culture as spiral. Mature spore chains are moderately short with 3–10, or sometimes more than 10, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar; sporulation may be unsatisfactory on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar and salts-starch agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; yellow-brown is modified by red on yeast-malt agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar; pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-fructose, and raffinose are utilized for growth. No growth or only traces of growth on iso-inositol, D-mannitol, and rhamnose.

Type strain shows the highest sequence similarity to: *S. graminofaciens*, AJ781329, 100%; *S. xantholiticus*, AB184349, 99.9%; *S. peucetius*, AB045887, 99.8%.

Source: not known.

Type strain: ATCC 15824, ATCC 19774, ATCC 23629, CBS 512.68, BCRC 12133, CECT 3274, DSM 40162, NBRC

13192, INA 10294, JCM 4388, NCIMB 12788, NRRL B-3366, NRRL-ISP 5162, RIA 1054, UNIQEM 160.

Sequence accession no. (16S rRNA gene): AB184325.

273. **Streptomyces labedae** Lacey 1987, 458[VP]

la.be′da.e. N.L. gen. masc. n. *labedae* of Labeda, named after David P. Labeda, who first recorded the difference between the type strain and second reference strain of *Saccharopolyspora erythraeus* designated by Waksman.

Spore chains are in long, open spirals (*Spirales*). The spore surface is spiny. Spores are moderate gray on most media and reddish gray on glycerol-asparagine or Czapek's agars. Substrate mycelium olive gray to dark reddish brown. Aerial mycelium white to pinkish, especially on glycerol-asparagine or Czapek's agars. Melanin pigments are not produced on Czapek's agar. Glucose, xylose, rhamnose, fructose, galactose, mannitol, and inositol are assimilated as sole carbon sources; arabinose, salicin, and sucrose are assimilated moderately well; raffinose is poorly assimilated. Wall chemotype I, with LL-A_2pm and glycine.

Type strain shows the highest sequence similarity to: *S. griseoincarnatus*, AJ781328, 100%; *S. erythrogriseus*, AJ781328, 100%; *S. variabilis*, DQ442551, 100%; *S. griseorubens*, AB184139, 99.9%; *S. griseoflavus*, AJ781322, 99.6%; *S. matensis*, AB184221, 99.6%; *S. althioticus*, AY999808, 99.3%; *S. paradoxus*, AB184628, 99.2%; *S. heliomycini*, AB184712, 99.1%; *S. collinus*, AB184123, 99.1%; *S. viridochromogenes*, DQ442555, 99.1%; *S. flaveolus*, AB184764, 99%; *S. bellus*, AB184849, 99%; *S. albogriseolus*, AJ494865, 99%; *S. viridodiastaticus*, AY999852, 99%; *S. violaceochromogenes*, AY999867, 99%; *S. malachitofuscus*, AB184282, 99%; *S. violaceorubidus*, AJ781374, 99%; *S. coerulescens*, AY999720, 99%.

Source: isolated from soil.

DNA G+C content (mol%): not known.

Type strain: Sanchez-Marroquin A-24, DSM 41446, NBRC 15864, IMRU 3737, JCM 9381, NRRL B-5616, NRRL-ISP 5059.

Sequence accession no. (16S rRNA gene): AB184704.

Further comments: Saccharopolyspora erythraeus (Waksman 1923) Waksman and Henrici 1948 emend. Labeda 1987 is illegitimate [Rules 37a, 51a and 53 of the *Bacteriological Code* (1990 Revision)] and the name *Streptomyces labedae* Lacey 1987 is provided for this taxon.

274. **Streptomyces laceyi** Manfio, Atalan, Zakrzewska-Czerwinska, Mordarski, Rodriguez, Collins and Goodfellow 2003b, 1219[VP] (Effective publication: Manfio, Atalan, Zakrzewska-Czerwinska, Mordarski, Rodriguez, Collins and Goodfellow 2003a, 254.)

la′cey.i. N.L. gen. masc. n. *laceyi* of Lacey, named in honor of John Lacey, an English microbiologist.

Forms extensively branched substrate and aerial hyphae. Spiral chains of smooth-surfaced spores are evident on aerial hyphae. Aerial spore mass varies from gray to yellow pink depending on the medium; similarly, the substrate mycelium color varies from yellow to yellow pink. Diffusible pigments are not produced. Degrades xanthine, but shows no activity against hippurate or nitrate. Cleaves methoxysuccinyl-L-alanine-L-lysine-7AMC, L-phenylalanine-7AMC, *N*-acetyl-L-phenylalanine-L-arginine-7AMC (endopeptidase substrates), benzylocarbonyl-L-arginine-7AMC, L-proline-7AMC, L-pyroglutamate-7AMC (exopeptidase substrates), 4MU-β-D-galactopyranoside, 4MU-*N*-acetyl-β-D-glucosaminide, 4MU-α-D-mannopyranoside (glycosides), and 4MU-α-D-pyrophosphate (inorganic ester) but not L-citrulline-7AMC, glutaryl-glycine-L-phenylalanine-7AMC, glutaryl-L-phenylananine-7AMC (endopeptidases), L-glutamine-7AMC, L-iso-leucine-7AMC, L-ornithine-7AMC (exopeptidases), 4MU-α-D-glucoside, 2-deoxy-β-D-glucopyranoside (glucosides), 4MU-elaidate, or 4MU-oleate (organic esters). Dextran, inulin, D(+)mannitol, citrate, and pyruvate are used as sole sources of carbon for energy and growth, but not *myo*-inositol. L-Histidine, potassium nitrate, and L-valine are used as sole carbon and nitrogen sources, but not L-hydroxyproline. Grows from 10–30°C and in the presence of sodium azide (0.01%, w/v), thallous acetate (0.001%, w/v), and neomycin sulfate (50 µg/ml), but shows no activity against *Bacillus subtilis* NCIMB 3610, *Candida albicans* CBS 562, *Micrococcus luteus* NCIMB 196, or *Streptomyces murinus* ISP 5091.

Type strain shows no sequence similarity over 99%.

Source: isolated from soil taken from meadow hay plots.

DNA G+C content (mol%): 69–74.

Type strain: C7654, DSM 41788, JCM 12606, NBRC 100783, NCIMB 13928.

Sequence accession no. (16S rRNA gene): AB249944.

275. **Streptomyces ladakanum** (Hanka, Evans, Mason and Dietz 1966) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium ladakanus* Hanka, Evans, Mason and Dietz 1966, 620)

la.da.ka′num. N.L. adj. *ladakanum* (*sic*) from Ladislav J. Hanka, who isolated the strain.

Spore chains in Section *Verticillati*, umbellate monoverticillate (biverticillate). Mature spore chains are generally short with 3 to 10 or more spores per chain. This morphology can be seen on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar, but sporulation may be poor on these media. Spore surface is smooth.

Color of colony: aerial mass color in the White or Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Abundant aerial mycelium is usually in the White color series; shorter or poorly developed aerial mycelium may be 2ba or 2db, pale yellow. Reverse side of colony is moderate orange to strong brown on yeast-malt agar; light or pale yellow on oatmeal agar; yellowish pink to grayish reddish orange on salts-starch agar, and grayish yellow to reddish brown or strong brown on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and D-fructose are utilized for growth. No growth or only traces of growth with L-arabinose, D-xylose, iso-inositol, D-mannitol, rhamnose, sucrose, and raffinose.

For sequence similarity, see type strain of *Streptomyces mobaraensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27441, JCM 4778, NBRC 13476, NRRL 3191.

Sequence accession no. (16S rRNA gene): AB184430.

Further comments: according to Labeda (1996), *Streptomyces ladakanum* (Hanka et al. 1966) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces mobaraensis* (Nagatsu and Suzuki 1963) Witt and Stackebrandt 1991.

According to Hatano et al. (2003), *Streptomyces ladakanum* (Hanka et al. 1966) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces mobaraensis* (Nagatsu and Suzuki 1963) Witt and Stackebrandt 1991.

276. **Streptomyces lanatus** Frommer 1959, 204[AL]

la.na′tus. L. masc. adj. *lanatus* woolly, referring to the nature of the aerial mycelium of the organism.

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50 spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Blue color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than yellow or brown not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19775, CBS 513.68, BCRC 12060, DSM 40090, NBRC 12787, JCM 4332, JCM 4588, NRRL B-2291, NRRL-ISP 5090, RIA 1055, UNIQEM 161.

Sequence accession no. (16S rRNA gene): AB184845.

277. **Streptomyces lateritius** (Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 67[AL] ("*Actinomyces lateritius*" Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 70)

la.te.ri′ti.us. L. masc. adj. *lateritius* made or consisting of bricks, intended to mean brick red (referring to the color of the aerial mycelium).

Spore chains in Section *Retinaculiaperti*, but spore chains representative of Section *Rectiflexibiles* are also common. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on salts-starch agar. Aerial mycelium is not produced on glycerol-asparagine agar and may be poorly developed on yeast-malt agar and oatmeal agar. Spore surface is warty.

Color of colony: aerial mass color in the Red color series on salts-starch agar. When sporulating aerial mycelium is formed on yeast-malt agar or oatmeal agar, it is in the Red color series. Reverse side of colony is grayed yellow is modified by violet or blue (see soluble pigment) on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed from violet to blue by addition of 0.05 M NaOH, and from violet or blue to red with 0.05 M HCl.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Blue or violet pigments found in medium in oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive when tested with 0.05 M NaOH or HCl. Violet pigment is changed to blue by 0.05 M NaOH and to red by 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, D-mannitol, and raffinose. Utilization of iso-inositol is doubtful.

Type strain shows the highest sequence similarity to: *S. venezuelae*, AB045890, 99.9%; *S. zaomyceticus*, EF178685, 99.7%; *S. exfoliatus*, AB184324, 99.7%; *S. wedmorensis*, DQ442557, 99.6%; *S. omiyaensis*, EF178697, 99.5%; *S. litmocidini*, AB184149, 99.5%; *S. yereyanensis*, EF178684, 99.3%; *S. narbonensis*, DQ445794, 99.2%.

Type strain: AS 4.1427, ATCC 19776, ATCC 19913, CBS 514.68, BCRC 13774, DSM 40163, NBRC 12788, INA 6993, JCM 4389, NRRL B-5349, NRRL B-5423, NRRL-ISP 5163, RIA 1056, UNIQEM 162, VKM Ac-1849, VKM Ac-577.

Sequence accession no. (16S rRNA gene): AJ781326.

278. **Streptomyces laurentii** Trejo, Dean, Pluscec, Meyers and Brown 1977, 642[AL]

lau.ren′ti.i. N.L. gen. masc. n. *laurentii* derived from latinization of Lawrence, after Lawrence Township, New Jersey, the origin of the soil isolate.

On oatmeal agar, the aerial mycelium is predominantly straight (Rectus) with rare primitive spirals of a single turn; however, on starch-casein agar, hooks and primitive spirals predominate. The spores are smooth as seen by electron microscopy. In shaken culture [18 h at 25°C in tryptone-yeast extract broth (ISP medium 1)], a dusty pink soluble pigment is produced and the whole mycelium fragments into arthrospores and rods of varying length.

On yeast extract malt agar (ISP medium 2): sporulation is scant as a faint pinkish blush on white aerial mycelium; reverse: burnt orange; soluble pigment: light rose. On oatmeal agar (ISP medium 3): sporulation is good and occurs rapidly within 4 d; aerial mycelium is grayish yellow pink; CHM no. 5ec; dusty pink; there is no distinctive reverse color or soluble pigment. On inorganic salts starch agar (ISP medium 4): sporulation is good; CHM no. 4ec; light

rose beige; reverse is reddish-orange; no soluble pigment. No melanin is produced on sodium caseinate-tyrosine agar (25 g sodium caseinate, 10 g $NaNO_3$, 1 g L-tyrosine, 1 liter tap water). Carbohydrate utilization was determined on the basal medium of Pridham and Gottlieb (1948) supplemented with individual carbon sources at 1% (w/v). The following carbohydrates, as the sole carbon source, support growth: glucose, xylose, galactose, melibiose, sucrose, and lactose. No growth on mannitol, inositol, sorbitol, arabinose, rhamnose, fructose, raffinose, and trehalose. Cell-wall hydrolysates contain LL-A_2pm.

Type strain shows the highest sequence similarity to: *S. roseofulvus*, AB184327, 99.2%; *S. bikiniensis*, X79851, 99%.

Source: isolated from soil from Lawrence Township, New Jersey, USA.

DNA G+C content (mol%): not known.

Type strain: ATCC 31255, DSM 41684, NBRC 15422, JCM 5063, PCM 2368.

Sequence accession no. (16S rRNA gene): AJ781342.

279. **Streptomyces lavendofoliae** (Kuchaeva, Krasil'nikov, Taptykova and Gesheva 1961) Pridham 1970, 19[AL] ("*Actinomyces lavendofoliae*" Kuchaeva, Krasil'nikov, Taptykova and Gesheva 1961, 120)

la.ven.do.fo.li'a.e. N.L. n. *lavendula* lavender; L. n. *folium* a leaf; N.L. gen. n. *lavendofoliae* (*sic*) of lavender leaf, referring to the color of the aerial mycelium.

Spore chains in Section *Retinaculiaperti*. Long, flexuous spore chains often terminate in spirals or hooks and loops of wide diameter. Mature spore chains have 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink or yellowish pink) on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigment (pale yellow to light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and usually in tyrosine agar and tryptone-yeast broth. Pigments other than melanoids are not formed in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and iso-inositol are utilized for growth. Utilization of fructose is doubtful. No growth or only traces of growth on sucrose, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. gobitricini*, AB184666, 99.8%; *S. luridus*, DQ442523, 99.4%.

Sequence accession no. (16S rRNA gene): AJ781336.

280a. **Streptomyces lavendulae subsp. lavendulae** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 944[AL] ("*Actinomyces lavendulae*" Waksman and Curtis 1916, 126)

la.ven.du'la.e. N.L. n. *lavendula* lavender; N.L. gen. n. *lavendulae* of lavender color.

Spore chains in Section *Retinaculiaperti* with many *Rectiflexibiles* spore chains as well as coils of wide diameter and some spirals. Mature spore chains generally have 10–50 spores per chain; longer chains are often observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red (or Gray) color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Characteristic color is between 3ge (light grayish yellowish brown) and 4ec or 5ec (grayish yellowish pink) color tabs of Tresner–Backus Color Wheels. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator (one observer reports slight change from yellowish brown to greenish brown by addition of 0.05 M NaOH).

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and usually in tyrosine agar and tryptone-yeast broth. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose is utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose. Limited growth with D-fructose.

Type strain shows the highest sequence similarity to: *S. cyaneofuscatus*, AB184860, 100%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. alboviridis*, AB184256, 100%; *S. fulvorobeus*, AB184711, 100%; *S. microflavus*, DQ445795, 100%; *S. praecox*, AB184293, 100%; *S. anulatus*, DQ026637, 100%; *S. flavofuscus*, AB249935, 100%; *S. cinereorectus*, AB184646, 100%; *S. griseoplanus*, AY999894, 100%; *S. lipmanii*, AB184148, 100%; *S. fimicarius*, AY999784, 100%; *S. sindenensis*, AB184759, 99.9%; *S. rubiginosohelvolus*, AB184240, 99.9%; *S. mediolani*, AB184674, 99.9%; *S. griseinus*, AB184205, 99.9%; *S. acrimycini*, AY999889, 99.9%; *S. pluricolorescens*, DQ442540, 99.9%; *S. argenteolus*, AB045872, 99.9%; *S. badius*, AY999783, 99.9%; *S. floridae*, AB184656, 99.8%; *S. albovinaceus*, AB249958, 99.8%; *S. globisporus* subsp. *globisporus*, EF178686, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.8%; *S. griseolus*, AB184768, 99.8%; *S. luridiscabiei*, AF361784, 99.8%; *S. baarnensis*, EF178688, 99.8%; *S. flavovirens*, DQ026635, 99.7%; *S. californicus*, AB184755, 99.7%; *S. parvus*, DQ442537, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. flavogriseus*, AJ494864, 99.6%; *S. olivoviridis*, AB184227, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. atroolivaceus*, AJ781320, 99.5%; *S. clavifer*, DQ026670, 99.4%; *S. yanii*, AB006159, 99.4%; *S. nitrosporeus*, EF178680, 99.4%; *S. albolongus*, AB184425,

Sequence accession no. (16S rRNA gene): D85116.

280b. **Streptomyces lavendulae subsp. grasserius** (Kuchaeva, Krasil'nikov, Taptykova and Gesheva 1961) Pridham 1970, 54[AL] ("*Actinomyces lavendulae grasserius*" Kuchaeva, Krasil'nikov, Taptykova and Gesheva 1961, 119)

gras.se′ri.us. Fr. n. *grasserié* a disease of silkworms; N.L. adj. *grasserius* grasserial (referring to the activity of the organism against silkworm jaundice virus, grasserié).

Spore chains of typical *Retinaculum-Apertum* type; poor growth on Czapek's solution agar. Produces the grasseriomycin complex (a streptothricin complex); inhibited by streptomycin.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 15875, ATCC 25457, CBS 690.69, DSM 40385, NBRC 13045, JCM 4056, JCM 4556, NRRL B-3072, NRRL B-3372, NRRL-ISP 5385, RIA 1237, RIA 746, VKM Ac-1178.

Sequence accession no. (16S rRNA gene): AY999841.

281. **Streptomyces lavenduligriseus** (Locci, Baldacci and Petrolini Baldan 1969) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium lavenduligriseum* Locci, Baldacci and Petrolini Baldan 1969, 59)

la.ven.du.li.gri′se.us. N.L. n. *lavendula* lavender; N.L. adj. *griseus* gray; N.L. masc. adj. *lavenduligriseus* gray and lavender colored.

Spore chains in Section *Rectiflexibiles* to *Retinaculiaperti* (one observer records monoverticillate sporophores). Clusters of short, flexuous spore chains include hooks, loops, and primitive spirals. Straight spore chains are also seen, and spore chains or clusters of sporophores sometimes seem to be opposite or in whorls. These do not appear to have the uniformity or even spacing characteristic of verticillate cultures. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar; sporulation is poor or absent on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray; 3ge, light grayish yellowish brown; 3ig, grayish yellowish brown; or 2fe, medium gray) on yeast-malt agar, oatmeal agar, and salts-starch agar. Aerial mycelium is poorly developed or absent on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (brown to grayish yellow on yeast-malt agar and oatmeal agar; grayish yellow or pale yellow on salts-starch agar and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. One of three observers reports reddish to orange pigment in the medium in yeast-malt agar and oatmeal agar, and yellow pigment in glycerol-asparagine agar. Two observers report no pigment in ISP media. When soluble pigment is produced, it is reported to be pH-sensitive, changing from red, orange, or yellow to violet with the addition of 0.05 M NaOH.

D-Glucose, L-arabinose, D-xylose, D-fructose, and D-mannitol are utilized for growth. Reports vary on utilization of iso-inositol. Utilization of rhamnose or sucrose is doubtful. No growth or only traces of growth with raffinose.

Type strain shows the highest sequence similarity to: *S. morookaense* AJ781349, 99.6%; *S. thioluteus*, AB184753, 99.2%; *S. abikoensis*, AB184537, 99.1%; *S. luteireticuli* AB249969, 99%; *S. sapporonensis*, AB184508, 99%.

283. **Streptomyces levis** Sveshnikova 1986, 574[VP] (Effective publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

le′vis. L. masc. adj. *levis* smooth.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1, oatmeal agar: aerial mycelium is pale pink to pale violet; substrate mycelium is brown; diffusible pigment is brown with grayish violet shadow. On starch-ammonia agar: aerial mycelium is not extant or poor, whitish; substrate mycelium is violet, gray-brown violet or plum black; diffusible pigment is pale violet, weak, or not extant. On glycerol-nitrate agar: aerial mycelium is white, poor; substrate mycelium is colorless to violet; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is light violet to light pink-violet; substrate mycelium is grayish-brownish yellow later grayish-brownish violet, plum black; no diffusible pigment. On organic agar 2: aerial mycelium is white to pale pink; substrate mycelium is brown to yellow brown; diffusible pigment is brown. Melanoid pigments are not formed. Grows on glucose, arabinose, xylose, raffinose, fructose, and sucrose; moderate growth on mannitol. Antibiotic pigment of group ribromycin-griseorodin having indicator character: alkaline reaction, violet; acidic reaction, red.

Type strain shows the highest sequence similarity to: *S. pseudogriseolus*, DQ442541, 99.5%; *S. capillispiralis*, AB184577, 99.5%; *S. carpinensis*, AB184574, 99.5%; *S. tuirus*, AB184690, 99.4%; *S. gancidicus*, AB184660, 99.4%; *S. azureus*, EF178674, 99.4%; *S. cellulosae*, DQ442495, 99.3%; *S. djakartensis*, AB184657, 99.2%; *S. afghaniensis*, AJ399483, 99.2%; *S. viridiviolaceus*, AY999854, 99.2%; *S. africanus*, AY208912, 99.2%; *S. caelestis*, X80824, 99.1%; *S. spinoverrucosus*, AB184578, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. misionensis*, EF178678, 99.1%; *S. paradoxus*, AB184628, 99%; *S. ghanaensis*, AY999851, 99%; *S. violaceus*, AB184315, 99%; *S. hawaiiensis*, AB184143, 99%; *S. vinaceusdrappus*, AY999929, 99%; *S. luteogriseus*, AB184379, 99%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99%; *S. geysiriensis*, DQ442501, 99%; *S. plicatus*, AB184291, 99%; *S. janthinus*, AB184851, 99%; *S. rochei*, AB184237, 99%; *S. minutiscleroticus*, EF178696, 99%; *S. roseoviolaceus*, AJ399484, 99%.

Type strain: ATCC 43686, DSM 41458, NBRC 15423, INA 9020, JCM 6924, NRRL B-16370, VKM Ac-835.

Sequence accession no. (16S rRNA gene): AB184670.

284a. **Streptomyces libani subsp. libani** Baldacci and Grein 1966, 196[AL]

li′ba.ni. L. gen. n. *libani* of Lebanon, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*. Tight terminal spirals are usually seen on moderately short chains of 10 or more spores. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs reported for aerial mass color on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar are d, light gray; e, medium gray; and 2dc and 2bc, yellowish gray. Nearest matching tabs reported for salts-starch agar are 3fe, light brownish gray; 4li, brownish gray; and 3ge, light yellowish brown. Reverse side of colony is gray or pale yellow to orange yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth. Utilization of L-arabinose is doubtful.

Type strain shows the highest sequence similarity to: *S. nigrescens*, DQ442530, 100%; *S. tubercidicus*, AJ621612, 100%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.7%; *S. libani* subsp. *rufus*, AJ781351, 99.7%; *S. caniferus*, AB184640, 99.6%; *S. catenulae*, AJ621613, 99.6%; *S. misakiensis*, AB217605, 99.6%; *S. sioyaensis*, DQ026654, 99.5%; *S. platensis*, AB045882, 99.5%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.2%; *S. lydicus*, Y15507, 99.1%; *S. chattanoogensis*, AJ621611, 99%.

Source: isolated from soil from Lebanon.

DNA G+C content (mol%): not known.

Type strain: ATCC 23732, CBS 753.72, DSM 40555, NBRC 13452, JCM 4322, JCM 4781, KCTC 9113, NCAIM B.01474, NCIMB 11012, NRRL B-3446, NRRL-ISP 5555, RIA 1413, VKM Ac-1905.

Sequence accession no. (16S rRNA gene): AB184414.

284b. **Streptomyces libani subsp. rufus** Baldacci and Grein 1966, 197[AL]

ru′fus. L. masc. adj. *rufus* red, reddish.

Moderate growth on Czapek's solution agar; aerial mycelium typically colored in shades of hazel-nut brown (*avellaneus*); hygroscopic; forms reddish violet diffusible pigment with some media. Produces libanomycin; exhibits anti-fungal activity; inhibited by streptomycin.

Type strain shows the highest sequence similarity to: *S. caniferus*, AB184640, 100%; *S. hygroscopius* subsp. *glebosus*, AB184479, 100%; *S. platensis*, AB045882, 99.9%; *S. libani* subsp. *libani*, AB184414, 99.7%; *S. tubercidicus*, AJ621612, 99.6%; *S. nigrescens*, DQ442530, 99.6%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.6%; *S. catenulae*, AJ621613, 99.3%; *S. ramulosus*, DQ026662, 99.3%; *S. misakiensis*, AB217605, 99.3%; *S. sioyaensis*, DQ026654, 99.2%; *S. monomycini*, DQ445790, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23731, CMI 130779, DSM 41230, NBRC 15424, JCM 4325, NCIMB 10976, NRRL B-3445, VKM Ac-600.

Sequence accession no. (16S rRNA gene): AJ781351.

285. **Streptomyces lienomycini** Gause and Maximova 1986a, 574[VP] (Effective publication: Gause and Maximova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

li.e.no.my.ci′ni. N.L. n. *lienomycinum* lienomycin; N.L. gen. n. *lienomycini* of lienomycin, intended to mean lienomycin producing.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: aerial mycelium is white, later gray; substrate mycelium is yellowish or gray brownish yellow; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is absent; substrate mycelium colorless; no diffusible pigment. On oatmeal agar: aerial mycelium is light gray; substrate mycelium colorless; no diffusible pigment. On starch-ammonia agar: aerial mycelium is grayish white; substrate mycelium yellowish; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is absent; substrate mycelium yellowish; no diffusible pigment. On organic agar 2: aerial mycelium is absent or whitish; substrate mycelium and diffusible pigment are gray brown. Melanoid pigments are formed. Good growth on xylose, fructose, inositol, sucrose, arabinose, mannitol, rhamnose, and raffinose. Antibiotic: lienomycin.

Type strain shows the highest sequence similarity to: *S. rubrogriseus*, AB184681, 99.9%; *S. violaceorubidus*, AJ781374, 99.7%; *S. anthocyanicus*, AB184631, 99.7%; *S. tricolor*, AB184687, 99.7%; *S. violaceoruber*, AF503492, 99.6%; *S. coelescens*, AF503496, 99.6%; *S. violaceolatus* AF503497, 99.5%; *S. humiferus*, AF503491, 99.5%; *S. tendae*, D63873, 99.5%; *S. coelicoflavus*, AB184650, 99.2%; *S. olivaceus*, AB184743, 99.2%; *S. pactum*, AB184398, 99.2%; *S. ambofaciens*, M27245, 99.1%; *S. matensis*, AB184221, 99.1%; *S. heliomycini*, AB184712, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 43687, DSM 41475, NBRC 15425, INA 478, JCM 6925, VKM Ac-1767.

Sequence accession no. (16S rRNA gene): AJ781353.

286. **Streptomyces lilacinus** (Nakazawa, Tanabe, Shibata, Miyake and Takewaka 1956) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces lilacinus*" Nakazawa, Tanabe, Shibata, Miyake and Takewaka 1956, 81; "*Verticillomyces lilacinus*" Shinobu 1965; *Streptoverticillium lilacinum* Locci, Baldacci and Petrolini Baldan 1969, 59)

li.la′ci.nus. N.L. masc. adj. *lilacinus* lilac colored.

Spore chains in Section *Verticillati*, umbellate monoverticillate (biverticillate). Spore chains are short, usually with 3–10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is yellow-brown plus red (grayish reddish brown to strong brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is somewhat pH-sensitive changing from brown to reddish brown with addition of 0.05 M NaOH and from brown to yellowish brown with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Red pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive when tested with 0.05 M NaOH or HCl, showing the same change noted for substrate color.

D-Glucose is utilized for growth; reports vary on positive utilization of iso-inositol. No growth or only trace of growth on L-arabinose, sucrose, D-xylose, D-mannitol, D-fructose, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. abikoensis*, AB184537, 99.7%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99.4%; *S. hiroshimensis*, AB184789, 99.4%; *S. caeruleus*, EF178675, 99.3%; *S. sapporonensis*, AB184508, 99.3%; *S. ehimensis*, AY999834, 99.3%; *S. cinnamoneus*, AB184850, 99.1%; *S. pseudoechinosporeus*, AB184100, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23930, CBS 914.68, BCRC 12421, CECT 3264, DSM 40254, NBRC 12884, NBRC 3944, JCM 4188, JCM 4648, NRRL B-1968, NRRL-ISP 5254, RIA 1180.

Sequence accession no. (16S rRNA gene): AB184819.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces lilacinus* is proposed as a *nomen revictum* (basonym: "*Streptomyces lilacinus*" Nakazawa et al. 1956).

According to Hatano et al. (2003), *Streptomyces lilacinus* (Nakazawa et al. 1956) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces kashmirensis* (*sic*) (Gupta and Chopra 1963b) Witt and Stackebrandt 1991.

287. **Streptomyces limosus** Lindenbein 1952, 379[AL]

li.mo′sus. L. masc. adj. *limosus* slimy, referring to the river bank slime from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains on suitable media generally 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar; no pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. canescens*, AB184117, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. hydrogenans*, AB184868, 100%; *S. odorifer*, Z76682, 100%; *S. violascens*, AY999737, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. sampsonii*, D63871, 99.8%; *S. koyangensis*, AY079156, 99.7%.

Source: isolated from river bank slime.

DNA G+C content (mol%): not known.

Type strain: ATCC 19778, CBS 531.68, BCRC 13700, DSM 40131, NBRC 12790, JCM 4393, KCTC 9033, NCIMB 12976, NRRL B-5413, NRRL-ISP 5131, RIA 1058, UNIQEM 165, VKM Ac-850.

Sequence accession no. (16S rRNA gene): AB184147.

288. **Streptomyces lincolnensis** Mason, Dietz and DeBoer 1963a, 555[AL]

lin.coln.en′sis. N.L. masc. adj. *lincolnensis* of or belonging to Lincoln, referring to the source of the soil from which the organism was isolated, *viz.* Gehring, near Lincoln, Nebraska, USA.

Spore chains in Section *Rectiflexibiles.* Mature spore chains are long and flexuous, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Representative color tabs are 2ba (pale yellow) from the Yellow color series; 2ca (pale yellow) and 3ca (pale orange yellow) from the Red color series. Reverse side of colony with no distinctive pigments (pale grayish yellow to orange yellow) on oatmeal agar and salts-starch agar; yellowish brown to brown on yeast-malt agar and olive brown to dark grayish brown on glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. A trace of yellow to greenish yellow pigment is found in the medium in oatmeal agar and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows no sequence similarity over 99%.

Source: isolated from soil in Lincoln, Nebraska.

DNA G+C content (mol%): not known.

Type strain: ATCC 25466, CBS 630.70, CBS 699.69, BCRC 11173, DSM 2013, DSM 40355, NBRC 13054, JCM 4287, JCM 4488, KCTC 1868, KCTC 9088, KCTC 9089, NCIMB 9413, NRRL 2936, NRRL-ISP 5355, RIA 1246, VKM Ac-727.

Sequence accession no. (16S rRNA gene): AB184279.

289. **Streptomyces lipmanii** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 952[AL] ("*Actinomyces lipmanii*" Waksman and Curtis 1916, 123)

lip.man′i.i. N.L. gen. masc. n. *lipmanii* of Lipman, named for Jacob Goodale Lipman (1874–1939) of the New Jersey Agricultural Experiment Station.

Spore chains in Section *Rectiflexibiles.* Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed on suitable media. This morphology is seen on yeast-malt agar and glycerol-asparagine agar. Sporulation may be poor on oatmeal agar and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on oatmeal agar, salts-starch agar and glycerol-asparagine agar; yellow to yellow-brown on yeast-malt agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on L-arabinose, iso-inositol, and raffinose. Utilization of sucrose is doubtful.

Type strain shows the highest sequence similarity to: *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. fulvorobeus*, AB184711, 100%; *S. microflavus*, DQ445795, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. alboviridis*, AB184256, 100%; *S. luridiscabiei*, AF361784, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. floridae*, AB184656, 99.9%; *S. praecox*, AB184293, 99.9%; *S. anulatus*, DQ026637, 99.9%; *S. pluricolorescens*, DQ442540, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. griseinus*, AB184205, 99.8%; *S. badius*, AY999783, 99.8%; *S. rubiginosohelvolus*, AB184240, 99.8%; *S. sindenensis*, AB184759, 99.8%; *S. mediolani*, AB184674, 99.8%; *S. californicus*, AB184755, 99.8%; *S. parvus*, DQ442537, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. globisporus* subsp. *globisporus*, EF178686, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. flavovirens*, DQ026635, 99.6%; *S. finlayi*, AY999788, 99.5%; *S. flavogriseus*, AJ494864, 99.5%; *S. yanii*, AB006159, 99.4%; *S. atroolivaceus*, AJ781320, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. pulveraceus*, AB184806, 99.4%; *S. celluloflavus*, AB184476, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. nitrosporeus*, EF178680, 99.3%; *S. spiroverticillatus*, AB184814, 99.2%; *S. sanglieri*, AB249945, 99.2%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. mutomycini*, AB249951, 99.2%; *S. atratus*, DQ026638, 99.1%; *S. candidus*, DQ026663, 99.1%; *S. gelaticus*, DQ026636, 99.1%; *S. cremeus*, AB184124, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19779, ATCC 3331, CBS 532.68, DSM 40070, HAMBI 1075, HUT 6059, NBRC 12791, NBRC 3410, NBRC 3721, IMET 40336, JCM 4058, JCM 4590, LMG 20047, NCIMB 9841, NRRL B-1229, NRRL B-2100, NRRL-ISP 5070, RIA 1059, RIA 85, UNIQEM 166.

Sequence accession no. (16S rRNA gene): AB184148.

Further comments: according to Lanoot et al. (2005b), *Streptomyces lipmanii* (Waksman and Curtis 1916) Waksman and Henrici 1948 is a later heterotypic synonym of *Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948 emend. Lanoot et al. 2005b.

290. **Streptomyces litmocidini** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 65[AL] ("*Actinomyces litmocidini*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 187)

lit.mo.ci.di′ni. N.L. gen. n. *litmocidini* of litmocidin.

Spore chains in Section *Rectiflexibiles* with some straight spore chains and occasional hooks or primitive spirals suggestive of Section *Retinaculiaperti*. Mature spore chains generally have 10–50 spores per chain; longer chains are often observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is colorless or characteristic grayed yellow on oatmeal agar, but the grayed yellow is modified by violet or red (depending on pH) on salts-starch agar, glycerol-asparagine agar, and sometimes on yeast-malt agar. Reverse color is changed from violet to blue by addition of 0.05 M NaOH, and from violet to red with 0.05 M HCl.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Violet, blue, or red pigments found in medium in yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; violet pigment is changed to blue by 0.05 M NaOH and to red by addition of 0.05 M HCl.

D-Glucose and L-arabinose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose. Variable reports on growth with D-xylose and D-fructose.

Type strain shows the highest sequence similarity to: *S. yereyanensis* EF178684, 99.8%; *S. exfoliatus*, AB184324, 99.6%; *S. venezuelae*, AB045890, 99.6%; *S. zaomyceticus*, EF178685, 99.6%; *S. omiyaensis*, EF178697, 99.5%; *S. wedmorensis*, DQ442557, 99.5%; *S. lateritius*, AB184324, 99.5%; *S. narbonensis*, DQ445794, 99.1%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99%.

291. **Streptomyces lomondensis** Johnson and Dietz 1969, 758[AL]

lo.mond.en′sis. N.L. masc. adj. *lomondensis* possibly pertaining to Loch Lomond, Scotland.

Warty to spiny spores borne on straight to open spiral to spiral sporophores (*Rectiflexibiles*, *Retinaculiaperti*, *Spirales*). Spores are poorly differentiated by carbon repligraphy. Blue aerial mycelium. Melanin-positive. The culture may be placed in the Red (R) and Blue (B) color series of Tresner and Backus (1963). Growth of the culture on carbon compounds in a synthetic medium was determined according to the procedure of Pridham and Gottlieb (1948). Growth is good on D-xylose, L-arabinose, rhamnose, D-fructose, D-galactose, D-glucose, D-mannose, maltose, sucrose, lactose, cellobiose, raffinose, dextrin, inulin, soluble starch, glycerol, D-mannitol, inositol, sodium acetate, and sodium succinate; slight on dulcitol and D-sorbitol. No growth on the control, salicin, phenol, cresol, sodium formate, sodium oxalate, sodium tartrate, or sodium salicylate. Grows at temperatures of 18–37°C. It does not grow at 55°C. The optimal temperature is 37°C. Produces the antibiotic lomofungin (lomondomycin, U-24792).

Type strain shows the highest sequence similarity to: *S. lusitanus*, AB184424, 99.4%; *S. bellus*, AB184849, 99.4%; *S. coerulescens*, AY999720, 99.4%; *S. purpurascens*, AJ399486, 99.4%; *S. janthinus*, AB184851, 99.3%; *S. coeruleorubidus*, AY999719, 99.3%; *S. parvulus*, AB184326, 99.3%; *S. roseoviolaceus*, AJ399484, 99.3%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.3%; *S. violaceus*, AB184315, 99.3%; *S. luteogriseus*, AB184379, 99.3%; *S. flavoviridis*, AB184842, 99.2%; *S. pilosus*, AB184161, 99.2%; *S. malachitospinus*, AB249954, 99.2%; *S. iakyrus*, AB184877, 99.1%; *S. indiaensis*, AB184553, 99.1%; *S. violaceorubidus*, AJ781374, 99.1%; *S. matensis*, AB184221, 99%; *S. spinoverrucosus*, AB184578, 99%; *S. hawaiiensis*, AB184143, 99%; *S. thermocarboxydus*, U94490, 99%; *S. tuirus*, AB184690, 99%.

Sequence accession no. (16S rRNA gene): AB184673.

292. **Streptomyces longisporoflavus** Waksman *in* Waksman and Lechevalier 1953, 94[AL]

lon.gi.spo.ro.fla′vus. L. adj. *longus* long; N.L. n. *spora* a spore; L. adj. *flavus* yellow; N.L. masc. adj. *longisporoflavus* long-spored, yellow.

Spore chains in Section *Spirales*. Open spirals; spore chains resembling *Retinaculiaperti* morphology are also common. Mature spore chains are long with 10–50 spores per chain; longer chains are often observed. This morphology may be observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on salts-starch agar. Aerial mycelium is poorly developed or absent on other ISP media. Reverse side of colony with no distinct pigments (colorless, grayish yellow, or light grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose. Utilization of iso-inositol and D-mannitol is doubtful.

No detailed sequence information available.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1453, ATCC 19781, ATCC 19915, ATCC 23932, CBS 915.68, BCRC 13775, DSM 40165, NBRC 12886, IMET 43506, INA 81/53, JCM 4396, LMG 19347, NRRL-ISP 5165, RIA 1133, RIA 312, VKM Ac-1003.

293. **Streptomyces longispororuber** Waksman *in* Waksman and Lechevalier 1953, 99[AL]

lon.gi.spo.ro.ru′ber L. adj. *longus* long; Gr. n. *spora* a seed; N.L. n. *spora* a spore; L. adj. *ruber* red; N.L. adj. *longispororuber* long-spored, red.

Spore chains in Section *Spirales*. Spirals may be found on oatmeal agar or salts-starch agar but are rarely found on yeast-malt agar or glycerol-asparagine agar. Sporulation is generally poor on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer reports only sterile aerial mycelium on these media. Spore surface was not determined. Spores are poorly defined in electron micrographs submitted by ISP observers.

Color of colony: aerial mass color in the Red color series (5ca or 7ca, light yellowish pink; 4ea, moderate yellowish pink; or 5cb or 6ec, grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer also reports 10ec, grayish purplish pink, in the Violet color series on salts-starch agar. Reverse side of colony with distinctive red pigments (strong or deep reddish orange or purplish pink). Substrate pigment is a pH indicator, changing from yellow orange or orange to pink with the addition of 0.05 M HCl and orange or pink to yellow orange or yellow with the addition of 0.05 M NaOH.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. Reports vary on the utilization of D-xylose. No growth or only traces of growth with sucrose, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. iakyrus*, AB184877, 99.4%; *S. coeruleorubidus*, AY999719, 99.2%; *S. lusitanus*, AB184424, 99.2%; *S. bellus*, AB184849, 99.2%; *S. coerulescens*, AY999720, 99.2%; *S. thermocarboxydus*, U94490, 99.1%; *S. viridodiastaticus*, AY999852, 99.1%; *S. albogriseolus*, AJ494865, 99.1%; *S. speibonae*, AF452714, 99.1%; *S. matensis*, AB184221, 99%; *S. griseorubens*, AB184139, 99%; *S. griseoflavus*, AJ781322, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27443, CBS 789.72, DSM 40599, NBRC 13488, INA 11668/54, JCM 4784, NCIMB 9629, NRRL B-3736, NRRL B-5761, NRRL-ISP 5599, PCM 2396, RIA 1449, VKM Ac-1735.

Sequence accession no. (16S rRNA gene): AB184440.

294. **Streptomyces longisporus** (Krasil'nikov 1941) Waksman *in* Waksman and Lechevalier 1953, 39[AL] ("*Actinomyces longisporus*" Krasil'nikov 1941, 47)

lon.gi'spo.rus. L. adj. *longus* long; Gr. n. *spora* a seed; N.L. n. *spora* a spore; N.L. adj. *longisporus* long-spored.

Spore chains in Section *Spirales*. Mature spore chains are moderately short, usually 10–50 spores per chain. Spore surface is spiny (one observer found smooth spores).

Color of colony: aerial mass color in the White color series on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar; White or Red (5cb grayish yellowish pink) color series on salts-starch agar. Reverse side of colony with no distinctive pigments (light or grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar to olive brown or brown on yeast-malt agar).

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoid are not found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23931, CBS 916.68, BCRC 13776, CCT 5006, DSM 40166, NBRC 12885, IMET 43090, INA 4417/56, JCM 4395, NRRL B-5336, NRRL-ISP 5166, PCM 2394, RIA 1134, VKM Ac-1896.

Sequence accession no. (16S rRNA gene): AJ399475.

295. **Streptomyces longwoodensis** Prosser and Palleroni 1981, 382[VP] (Effective publication: Prosser and Palleroni 1976, 321.)

long.wood.en'sis. N.L. masc. adj. *longwoodensis* of or belonging to Longwood, named after Longwood Gardens in Kennett Square, Pennsylvania, USA.

Strain produces a substrate mycelium, which does not fragment into spores, and an aerial mycelium, which later forms spore chains. After 14 d of incubation at 28°C, the spore chains appear spiral in form with greater than 10 spores per chain (range: 5 to >50). Spores are smooth and range in size from 1.2 × 0.32 μm to 1.8 × 0.74 μm. Does not hydrolyze hippurate; decomposes adenine, hypoxanthine, and tyrosine but not xanthine; and it slowly peptonizes skim milk. The cell wall of this organism contains LL-A_2pm.

Type strain shows the highest sequence similarity to: *S. galbus*, X79852, 99.9%; *S. bungoensis*, AB184696, 99.7%; *S. capoamus*, AB045877, 99.6%; *S. corchorusii*, AB184267, 99.4%; *S. canarius*, AB184396, 99.3%; *S. olivaceoviridis*, AB184288, 99.2%; *S. curacoi*, EF626595, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: Roche X-14537, ATCC 29251, BCRC 12034, DSM 41677, NBRC 14251, JCM 4976, KCTC 9783, NRRL B-16923.

Sequence accession no. (16S rRNA gene): AB184580.

296. **Streptomyces lucensis** Arcamone, Bertazzoli, Canevazzi, DiMarco, Ghione and Grein 1957, 119[AL]

lu.cen'sis. L. masc. adj. *lucensis* of or belonging to Lucca, a city in Italy, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*. Flexuous spore chains and imperfect spirals are common together with some regular open spirals of 4 or more turns; mature spore chains have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is hairy to spiny.

Color of colony: aerial mass color in the in the Gray color series (brownish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments

(colorless to pale grayish yellow or light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and sucrose are utilized for growth. No growth or only trace of growth with iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. niveoruber*, DQ445796, 99.5%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 17804, ATCC 25468, CBS 701.69, DSM 40317, NBRC 13056, JCM 4490, NCIMB 12679, NRRL B-16066, NRRL B-5626, NRRL-ISP 5317, RIA 1248, VKM Ac-1737.

Sequence accession no. (16S rRNA gene): DQ442522.

297. **Streptomyces luridiscabiei** Park, Kim, Kwon, Wilson, Yu, Hur and Lim 2003, 2053[VP]

lu.ri.di.sca'bi.ei. L. adj. *luridus* pale yellow; L. n. *scabies* roughness, scabbiness; N.L. gen. n. *luridiscabiei* pale yellow, scab-causing bacteria.

Spores are yellow-white, smooth, and borne in monoverticillus flexuous spore chains. Melanin is produced on tyrosine and peptone agars. L-Arabinose, D-fructose, D-glucose, D-mannitol, raffinose, rhamnose, sucrose, D-xylose, and iso-inositol are utilized for growth. Minimum pH for growth is 4.5. Sensitive to 5, 6, and 7% (w/v) NaCl, 100 µg/ml thallium acetate, 0.1% (w/v) phenol, 25 and 100 µg/ml oleandomycin, and 20 µg/ml streptomycin, but not to 10 µg/ml thallium acetate, 0.5 µg/ml crystal violet, or 10 IU/ml penicillin.

Type strain shows the highest sequence similarity to: *S. fulvorobeus*, AB184711, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. alboviridis*, AB184256, 99.9%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.8%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.8%; *S. microflavus*, DQ445795, 99.8%; *S. cinereorectus*, AB184646, 99.7%; *S. fimicarius*, AY999784, 99.7%; *S. mediolani*, AB184674, 99.7%; *S. rubiginosohelvolus*, AB184240, 99.7%; *S. griseinus*, AB184205, 99.7%; *S. badius*, AY999783, 99.7%; *S. anulatus*, DQ026637, 99.7%; *S. praecox*, AB184293, 99.7%; *S. flavofuscus*, AB249935, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. californicus*, AB184755, 99.7%; *S. pluricolorescens*, DQ442540, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. griseoplanus*, AY999894, 99.7%; *S. sindenensis*, AB184759, 99.7%; *S. floridae*, AB184656, 99.7%; *S. acrimycini*, AY999889, 99.6%; *S. griseus* subsp. *griseus*, AY207604, 99.6%; *S. griseolus*, AB184768, 99.6%; *S. flavogriseus*, AJ494864, 99.5%; *S. parvus*, DQ442537, 99.5%; *S. halstedii*, EF178695, 99.5%; *S. flavovirens*, DQ026635, 99.5%; *S. finlayi*, AY999788, 99.4%; *S. pulveraceus*, AB184806, 99.3%; *S. atroolivaceus*, AJ781320, 99.3%; *S. globisporus* subsp. *globisporus*, EF178686, 99.3%; *S. olivoviridis*, AB184227, 99.3%; *S. griseobrunneus*, AB249912, 99.2%; *S. nitrosporeus*, EF178680, 99.2%; *S. yanii*, AB006159, 99.2%; *S. celluloflavus*, AB184476, 99.2%; *S. bacillaris*, AB184439, 99.2%; *S. clavifer*, DQ026670, 99.2%; *S. albolongus*, AB184425, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. sanglieri*, AB249945, 99.1%; *S. baarnensis*, EF178688, 99.1%; *S. gelaticus*, DQ026636, 99%; *S. mutomycini*, AB249951, 99%; *S. atratus*, DQ026638, 99%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99%; *S. candidus*, DQ026663, 99%. Source: isolated from raised corky lesions on potato cv. Atlantic and pathogenic on potato cv. Daeji-ma.

DNA G+C content (mol%): 70.3.

Type strain: S63, KACC 20252, LMG 21390.

Sequence accession no. (16S rRNA gene): AF361784.

298. **Streptomyces luridus** (Krasil'nikov, Korenyako, Meksina, Valedinskaya and Veselov 1957) Waksman 1961, 237[AL] ("*Actinomyces luridus*" Krasil'nikov, Korenyako, Meksina, Valedinskaya and Veselov 1957, 563)

lu'ri.dus. L. adj. *luridus* pale yellow, ghostly pallid (probably referring to the color of the vegetative mycelium).

Spore chains in Section *Retinaculiaperti* with characteristic range of flexuous spore chains, hooks, loops, and occasional spirals (spirals rare). Mature spore chains generally have 10–50 spores per chain; longer chains are often observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar in 14 d. Sporulation aerial mycelium in the Red color series usually develops on oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 21 d. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar, tyrosine agar, and tryptone yeast broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and iso-inositol are utilized for growth. No growth or only traces of growth on sucrose, D-mannitol, rhamnose, and raffinose. Utilization of D-fructose is doubtful.

Type strain shows the highest sequence similarity to: *S. gobitricini*, AB184666, 99.5%; *S. lavendofoliae*, AJ781336, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1458, ATCC 19782, CBS 534.68, BCRC 13684, DSM 40081, NBRC 12793, INMI 111, JCM 4591, LMG 19365, NRRL B-5409, NRRL-ISP 5081, RIA 1061, UNIQEM 168, VKM Ac-245.

Sequence accession no. (16S rRNA gene): DQ442523.

299. **Streptomyces lusitanus** Villax 1963, 661[AL]

lu.si.ta′nus. L. masc. adj. *lusitanus* of or belonging to *Lusitania*, the Roman name of Portugal.

Spore chains in Section *Spirales*. Spirals are best developed on salts-starch agar and glycerol-asparagine agar; flexuous chains as well as open spirals and imperfect spirals are common on yeast-malt agar and oatmeal agar. Mature spore chains generally are long with 10 to 50 or more spores per chain. Spore surface is spiny with short spines. Some spores may appear smooth.

Color of colony: aerial mass color in the Gray or White color series on yeast-malt agar, oatmeal agar, salts-starch agar and glycerol-asparagine agar. Nearest matching color tabs in the Gray color series are 3fe, light brownish gray, and 5fe, light grayish reddish brown. Reverse side of colony with no distinctive pigments (pale or grayish yellow on oatmeal agar and glycerol-asparagine agar; olive brown or yellowish brown on yeast-malt agar and salts-starch agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment (or only a trace of yellow or pale olive) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and sucrose are utilized for growth. No growth or only traces of growth with raffinose.

Type strain shows the highest sequence similarity to: *S. thermocarboxydus*, U94490, 99.5%; *S. coerulescens*, AY999720, 99.4%; *S. bellus*, AB184849, 99.4%; *S. lomondensis*, AB184673, 99.4%; *S. gancidicus*, AB184660, 99.4%; *S. pseudogriseolus*, DQ442541, 99.4%; *S. capillispiralis*, AB184577, 99.3%; *S. matensis*, AB184221, 99.3%; *S. longispororuber*, AB184440, 99.2%; *S. coeruleorubidus*, AY999719, 99.2%; *S. purpurascens*, AJ399486, 99.2%; *S. spinoverrucosus*, AB184578, 99.2%; *S. cellulosae*, DQ442495, 99.2%; *S. griseoloalbus*, AB184275, 99.1%; *S. parvulus*, AB184326, 99%; *S. speibonae*, AF452714, 99%; *S. iakyrus*, AB184877, 99%; *S. indiaensis*, AB184553, 99%; *S. viridodiastaticus*, AY999852, 99%; *S. albaduncus*, AY999757, 99%; *S. albogriseolus*, AJ494865, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 15842, ATCC 27444, CBS 765.72, BCRC 11552, DSM 40568, NBRC 13464, JCM 4785, NCIMB 9585, NRRL B-12501, NRRL B-5637, NRRL-ISP 5568, RIA 1425, VKM Ac-1194.

Sequence accession no. (16S rRNA gene): AB184424.

300. **Streptomyces luteireticuli** (*ex* Katoh and Arai 1957) Hatano, Nishii and Kasai 2003, 1528[VP] ("*Streptoverticillium luteoreticuli*" Katoh and Arai 1957)

lu.te.i.re.ti′cu.li. L. adj. *luteus* yellow; L. n. *reticulum* net; N.L. gen. n. *luteireticuli* of a yellow net.

Spore chains in Section Umbellate Monoverticillate (=*Streptomyces Verticillati*, biverticillate). Mature spore chains are generally short with 3 to 10 or more spores per chain. This morphology is seen on oatmeal agar and sometimes on salts-starch agar. Sporulating aerial mycelium is usually thin or absent on yeast-malt agar or glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or Gray color series on oatmeal agar. Nearest matching color tabs in the Yellow color series are 1dc and 1½ec, pale yellow green, and 2db, pale yellow. Nearest matching tabs in the Gray color series are 2dc, yellowish gray, and 2ge, light olive brown. Reverse side of colony with no distinctive pigments (olive brown to dark brown on yeast-malt agar, grayish yellow or yellowish brown to olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellowish to greenish yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose and iso-inositol are utilized for growth. Utilization of L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose is doubtful since only a small amount of growth is found on these carbon sources.

Type strain shows the highest sequence similarity to: *S. abikoensis*, AB184537, 99.3%; *S. sapporonensis*, AB184508, 99.2%; *S. ehimensis*, AY999834, 99.2%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99.1%; *S. varsoviensis*, DQ026653, 99.1%; *S. lavenduligriseus*, DQ442515, 99%; *S. thioluteus*, AB184753, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27446, CBS 723.72, DSM 40509, ISP 5509, JCM 4788, NBRC 13422, RIA 1383.

Sequence accession no. (16S rRNA gene): AB249969.

301. **Streptomyces luteogriseus** Schmitz, Deak, Crook and Hooper 1964, 89[AL]

lu.te.o.gri′se.us. L. adj. *luteus* golden yellow; N.L. adj. *griseus* gray; N.L. masc. adj. *luteogriseus* grayish, golden-yellow, referring to the yellowish gray color of sporulating aerial mycelium on certain media.

Spore chains in Section *Spirales*. Mature spore chains generally contain 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs are 5fe, light grayish reddish brown, and 2dc, yellowish gray. One observer also reports aerial mycelium in the Red color series (5dc, grayish yellowish pink) on oatmeal agar and salts-starch agar. Reverse side of colony is strong yellowish brown to dark brown on yeast-malt agar; grayish yellow to olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth, but the reaction may be weak in tyrosine agar. Yellow to brown pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. janthinus*, AB184851, 99.5%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.5%; *S. roseoviolaceus*, AJ399484, 99.5%; *S. violaceus*, AB184315, 99.5%; *S. hawaiiensis*, AB184143, 99.4%; *S. tuirus*, AB184690, 99.4%; *S. arenae*, AB249977, 99.4%; *S. lomondensis*, AB184673, 99.3%; *S. flavoviridis*, AB184842, 99.2%; *S. parvulus*, AB184326, 99.2%; *S. pilosus*, AB184161, 99.2%; *S. massasporeus*, AB184152, 99.2%; *S. purpurascens*, AJ399486, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. malachitospinus*, AB249954, 99.1%; *S. rochei*, AB184237, 99%; *S. minutiscleroticus*, EF178696, 99%; *S. geysiriensis*, DQ442501, 99%; *S. bellus*, AB184849, 99%; *S. plicatus*, AB184291, 99%; *S. ghanaensis*, AY999851, 99%; *S. levis*, AB184670, 99%; *S. vinaceusdrappus*, AY999929, 99%.

Source: not known.

DNA G+C content (mol%): not known.

302. **Streptomyces luteosporeus** Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium album* Locci, Baldacci and Petrolini Baldan 1969, 59)

lu.te.o.spo′re.us. L. adj. *luteus* yellow; Gr. n. *spora* a seed and in biology a spore; N.L. masc. adj. *luteosporeus* yellow spored.

Spore chains are usually shorter. Reverse colors varying from yellow to hazel-nut yellow. Aerial mycelium colors are lighter, tending toward pinkish beige on glucose-asparagine agar, glycerol-asparagine agar, inorganic salts-starch agar, and yeast extract-malt extract agar. Melanin pigment is not produced. L-Methionine, L-proline, and shikimic acid are utilized, but not coumarin, mannitol, melibiose, raffinose, sorbitol, or DL-α-aminobutyric acid. Esculin and L-tyrosine are degraded, but not citrate. H_2S is not produced. Acid is produced from D-ribose and trehalose, but not from D-galactose, D-fructose, or *myo*-inositol. *Aspergillus niger* is not inhibited. Growth is as good at 37°C as at 27°C. Aerial mycelium is better at 37°C. The type strain produces acetopyrrothine (thiolutin).

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 33049, JCM 4542, DSM 40833, NBRC 14657, NRRL 2401, VKM Ac-927.

Sequence accession no. (16S rRNA gene): DQ442525.

Further comments: for the transfer of *Streptoverticillium album* Locci et al. 1969 to the genus *Streptomyces* Waksman and Henrici 1943, it is necessary to substitute a new specific epithet to produce *Streptomyces luteosporeus* because there is a senior homonym, *Streptomyces albus* (Rossi Doria 1891) Waksman and Henrici 1943 included on the Approved Lists of Bacterial Names [Rules 34a and 41a of the *Bacteriological Code* (1990 Revision)].

303. **Streptomyces luteoverticillatus** (Shinobu 1956) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces luteoverticillatus*" Shinobu 1956; "*Verticillomyces luteoverticillatus*" Shinobu 1965; *Streptoverticillium luteoverticillatum* Locci, Baldacci and Petrolini Baldan 1969, 59)

lu.te.o.ver.ti.cil.la′tus. L. adj. *luteus* yellow; L. n. *verticillus* a whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *luteoverticillatus* yellow, whorled.

Spore chains in Section *Verticillati*, umbellate monoverticillate (biverticillate). Mature spore chains generally 10 to 20 or more spores per chain after 21 d on salts-starch agar or yeast-malt agar. Aerial mycelium is poorly developed or absent on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. Absence of good aerial mycelium on various media was also noted by Shinobu in his original description (op. cit). Spore surface is smooth.

Color of colony: mature aerial mycelium in the Red or Yellow color series on salts-starch agar; it is absent or poorly developed (white or yellow) on other ISP media. Reverse side of colony with no distinctive pigments (light brown to grayed yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow pigment is found in medium in yeast-malt agar, oatmeal agar, and salts-starch agar after 14–21 d; it is not a pH indicator.

D-Glucose, iso-inositol, and D-fructose are utilized for growth. No growth or only traces of growth on L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose.

For sequence similarity, see type strain of *Streptomyces abikoensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23933, CBS 917.68, BCRC 13323, DSM 40038, NBRC 12887, NBRC 3840, JCM 4099, JCM 4649, NCIMB 9720, NRRL B-1995, NRRL-ISP 5038, RIA 1109, VKM Ac-889.

Sequence accession no. (16S rRNA gene): AB184803.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces luteoverticillatus* is proposed as a *nomen revictum* (basonym: "*Streptomyces luteoverticillatus*" Shinobu 1956).

According to Hatano et al. (2003), *Streptomyces luteoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces abikoensis* (Umezawa et al. 1951) Witt and Stackebrandt 1991.

304. **Streptomyces lydicus** DeBoer, Dietz, Silver and Savage 1955b, 886[AL]

ly′di.cus. L. n. *Lydia* an ancient state in Asia Minor; N.L. masc. adj. *lydicus* of or belonging to Lydia.

Spore chains in Section *Spirales*. Spirals are sometimes at the tips of long spore chains suggesting *Retinaculiaperti* morphology. Mature spore chains generally have 10–50 or sometimes more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray, to 3ih, dark gray) on yeast-malt agar and oatmeal agar; Gray or Yellow (2ba, pale yellow) or White color series on salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless, pale grayish-yellow or orange-yellow) on yeast No distinctive pigments (colorless, pale grayish-yellow or orange-yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth, according to two of three observers. The third observer records some darkening of peptone-yeast-iron agar and a trace of dark pigment on tyrosine agar, but not darkening of tryptone-yeast broth. No pigment (or only a trace of yellow) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, sucrose, and raffinose are utilized for growth. Utilization of rhamnose is doubtful.

Type strain shows the highest sequence similarity to: *S. chattanoogensis*, AJ621611, 99.8%; *S. sioyaensis*, DQ026654, 99.3%; *S. rimosus* subsp. *paromomycinus*, AJ621610, 99.3%; *S. chrestomyceticus*, AJ621609, 99.3%; *S. tubercidicus*, AJ621612, 99.1%; *S. libani* subsp. *libani*, AB184414, 99.1%; *S. nigrescens*, DQ442530, 99%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1412, ATCC 25470, CBS 703.69, BCRC 11919, CECT 3163, DSM 40461, HAMBI 1063, NBRC 13058, IMET 43531, JCM 4492, LMG 19331, NCIMB 12977, NRRL 2433, NRRL-ISP 5461, RIA 1250, VKM Ac-1869.

Sequence accession no. (16S rRNA gene): Y15507.

305. **Streptomyces macrosporus** (*ex* Krasil'nikov, Agre, Dorokhova and Sokolov 1968) Goodfellow, Lacey and Todd 1988, 328[VP] (Effective publication: Goodfellow, Lacey and Todd 1987a, 3148.) ("*Streptomyces macrosporus*" Krasil'nikov, Agre, Dorokhova and Sokolov 1968)

ma.cro.spo′rus. Gr. adj. *makros* long, large, Gr. n. *spora* seed; N.L. masc. adj. *macrosporus* large spored.

Spores mostly in tight spirals of up to six turns and 50 spores but sometimes in short straight chains of only five spores. Spores appear warty in transmission electron micrographs but are characteristically wrinkled in scanning electron micrographs, 0.7–1.8 × 0.7–1.6 µm, sometimes broader than long, mean 1.12 × 0.96 µm. Growth at 40°C on half-strength nutrient and V-8 juice agars is good; aerial mycelium is in the Green color series near 24ih (Tresner and Backus, 1963), with white flecks, although may be thin and white on half-strength nutrient agar. At 25°C, small colonies only are formed, sometimes with sparse white aerial mycelium. Substrate mycelium is colorless to dark brown with no distinctive pigments but often crystalline deposits are found in the agar. Melanoid pigments are not produced on peptone iron agar. No soluble pigments. Degrades esculin, arbutin, casein, DNA, gelatin, RNA, starch, and L-tyrosine; utilizes D-fructose, *myo*-inositol, D-mannose, L-rhamnose, trehalose, and D-xylose as sole carbon sources, and L-arginine, L-phenylalanine, potassium nitrate, and L-threonine as sole nitrogen sources. Proteolysis and lipolysis evident on egg yolk agar; pectin hydrolyzed; hydrogen sulfide produced but nitrate not reduced.

Type strain shows no sequence similarity over 99%.

Source: isolated from sewage compost and soil.

DNA G+C content (mol%): not known.

Type strain: K44, A1201, ATCC 51533, DSM 41449, HUT 6608, NBRC 14748, INMI 2892, JCM 6305, NCIMB 12473, VKM Ac-777.

Sequence accession no. (16S rRNA gene): Z68099.

306. **Streptomyces malachitofuscus** (*ex* Preobrazhenskaya et al. 1964) Preobrazhenskaya and Terekhova 1986, 574[VP] (Effective publication: Preobrazhenskaya and Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces malachitofuscus*" Preobrazhenskaya et al. 1964; "*Streptomyces malachitofuscus*" Pridham 1970)

ma.la.chi.to.fus′cus. L. n. *malache* the mallow; L. adj. *fuscus* dark or tawny; N.L. masc. adj. *malachitofuscus* mallow, dark (dark green).

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50 spores per chain on yeast-malt agar, oatmeal agar, and salts-starch agar. Shorter spore chains, especially on glycerol-asparagine agar, may form irregular or incomplete spirals, loops, and hooks. Spore surface is spiny to hairy.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray to 5fe, light reddish grayish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is nearly colorless to yellow or yellowish gray on oatmeal agar and salts-starch agar; grayish olive to olive brown on glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment is found in medium in salts-starch agar and glycerol-asparagine agar; a trace of yellow or yellow-brown pigment may or may not be found in yeast-malt agar and oatmeal agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and sucrose are utilized for growth. No growth or only traces of growth with raffinose.

Type strain shows the highest sequence similarity to: *S. griseoflavus*, AJ781322, 99.3%; *S. matensis*, AB184221, 99.3%; *S. griseorubens*, AB184139, 99.1%; *S. labedae*, AB184704, 99%; *S. griseoincarnatus*, AJ781328, 99%; *S. erythrogriseus*, AJ781328, 99%; *S. variabilis*, DQ442551, 99%; *S. flaveolus*, AB184764, 99%; *S. violaceorubidus*, AJ781374, 99%; *S. paradoxus*, AB184628, 99%; *S. glaucescens*, AB184843, 99%; *S. albaduncus*, AY999757, 99%; *S. gancidicus*, AB184660, 99%; *S. griseoloalbus*, AB184275, 99%; *S. djakartensis*, AB184657, 99%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB184282.

307. **Streptomyces malachitospinus** (*ex* Preobrazhenskaya et al. 1957) Preobrazhenskaya and Terekhova 1986, 574[VP] (Effective publication: Preobrazhenskaya and Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces malachitospinus*" Preobrazhenskaya et al. 1957)

ma.la.chi.to.spi′nus. L. n. *malache* the mallow the mallow; L. adj. *spineus* spiny; N.L. masc. adj. *malachitospinus* spiny and mallow green.

Spore chains are spiral (*Spirales*); spores are spiny, spines are long. On mineral agar 1, glycerol-nitrate agar, oatmeal agar: aerial mycelium is light gray; substrate mycelium is green; no diffusible pigment. On starch-ammonia agar: aerial mycelium is absent or light gray; substrate mycelium is green; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is white to light gray; substrate mycelium is yellowish green; no diffusible pigment. On organic agar 2: aerial mycelium is white or light gray; substrate mycelium is yellowish to greenish; no diffusible pigment. Color of substrate mycelium is a result of green pigment ferroverdin. Melanoid pigments are not formed. Glucose, arabinose, galactose, glycerol, and starch are utilized for growth; no growth with sucrose. Antibiotic: not isolated. Strain INMI 217^T builds a physiologically active substance which stimulates the building of zygotes in Mucorales.

Type strain shows the highest sequence similarity to: *S. parvulus*, AB184326, 99.3%; *S. violaceorubidus*, AJ781374, 99.2%; *S. lomondensis*, AB184673, 99.2%; *S. pactum*, AB184398, 99.2%; *S. luteogriseus*, AB184379, 99.1%; *S. rubrogriseus*, AB184681, 99%; *S. olivaceus*, AB184743, 99%; *S. tendae*, D63873, 99%.

Type strain: INMI 217, INA 316, NBRC 101004.

Sequence accession no. (16S rRNA gene): AB249954.

308. **Streptomyces malaysiensis** Al-Tai, Kim, Kim, Manfio and Goodfellow 1999, 1401[VP]

mal.ay.si.en′sis. N.L. masc. adj. *malaysiensis* of or belonging/pertaining to Malaysia, the source of the soil from which the organism was isolated.

Forms extensively branched substrate hyphae (0.3–0.5 µm in diameter) and aerial hyphae which differentiate into tight, spiral spore chains. The appearance of the spores ranges from cylindrical to barrel-shaped (1.3–1.0 × 1.5 µm) and the spore surface is rugose. On inorganic salts-starch agar, the aerial spore-mass color is gray and a yellow diffusible pigment is formed. Xanthine is not degraded. Growth does not occur at 10 or 45°C.

Type strain shows no sequence similarity over 99%.

Source: isolated from a soil sample collected at Tasek Bera, Malaysia's first Ramsar Site.

DNA G+C content (mol%): 72.2.

Type strain: ATB-11, ATCC BAA-13, DSM 41697, NBRC 16446, JCM 10672.

Sequence accession no. (16S rRNA gene): AB249918.

309. **Streptomyces mashuensis** (Sawazaki, Suzuki, Nakamura, Kawasaki, Yamashita, Isono, Anzai, Serizawa and Sekiyama 1955) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces mashuensis*" Sawazaki, Suzuki, Nakamura, Kawasaki, Yamashita, Isono, Anzai, Serizawa and Sekiyama 1955, 46; "*Verticillomyces mashuensis*" Shinobu 1965; *Streptoverticillium mashuense* Locci, Baldacci and Petrolini Baldan 1969, 59)

ma.shu.en′sis. N.L. masc. adj. *mashuensis* of or pertaining to Lake Mashu, Japan.

Spore chains in Section *Verticillati*, umbellate monoverticillate (biverticillate). Spore chains are short with 3–10, or sometimes more than 10, spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Mature aerial mycelium may be poorly developed on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow to orange yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; olive brown to brown on yeast-malt agar).

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, sucrose, and D-fructose are utilized for growth. Utilization of iso-inositol is doubtful. No growth or only traces of growth on L-arabinose, D-xylose, D-mannitol, rhamnose, and raffinose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23934, CBS 279.65, CBS 918.68, BCRC 12420, DSM 40221, IFM 1082, NBRC 12888, IMET 42941, JCM 4059, JCM 4650, NRRL B-3352, NRRL B-8164, NRRL-ISP 5221, RIA 1165, VKM Ac-949.

Sequence accession no. (16S rRNA gene): X79323.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces mashuensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces mashuensis*" Sawazaki et al. 1955).

According to Hatano et al. (2003), *Streptomyces mashuensis* (Sawazaki et al. 1955) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces kishiwadensis* (Shinobu and Kayamura 1964) Witt and Stackebrandt 1991.

310. **Streptomyces massasporeus** Shinobu and Kawato 1959, 283[AL]

mas.sa.spo′re.us. L. n. *massa* mass, lump; N.L. n. *spora* a spore; N.L. masc. adj. *massasporeus* mass, spore, referring to the coalescence of spores into moist masses.

Spore chains in Section *Spirales*, but spore chains representative of Section *Retinaculiaperti* are also present. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Special morphological characteristics: spores frequently coalesce to form moist masses of spores. Small masses may form from single spiral spore chains of large masses may form by the coalescence of many spirals.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Red or White series on oatmeal agar. Reverse side of colony is grayed yellow modified by red or violet (see pH) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed from violet to red by addition of 0.05 M HCl and from red to reddish violet to blue violet by addition of 0.05 M NaOH.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Red pigments found in medium in oatmeal agar and glycerol-asparagine agar. One observer detected red pigment in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 14 d and violet pigment in these media at 21 d; changes in color from violet to blue by addition of 0.05 M NaOH and from violet to red by addition of 0.05 M HCl were also noted.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. hawaiiensis*, AB184143, 99.7%; *S. indiaensis*, AB184553, 99.6%; *S. arenae*, AB249977, 99.4%; *S. purpurascens*, AJ399486, 99.3%; *S. luteogriseus*, AB184379, 99.2%; *S. coerulescens*, AY999720, 99%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99%; *S. janthinus*, AB184851, 99%; *S. roseoviolaceus*, AJ399484, 99%; *S. violaceus*, AB184315, 99%; *S. bellus*, AB184849, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1433, ATCC 19785, CBS 537.68, BCRC 13647, DSM 40035, NBRC 12796, NBRC 3841, JCM 4139, JCM 4593, LMG 19362, NRRL B-3300, NRRL-ISP 5035, RIA 1064, RIA 652, UNIQEM 171, VKM Ac-578.

Sequence accession no. (16S rRNA gene): AB184152.

311. **Streptomyces matensis** Margalith, Beretta and Timbal 1959, 71[AL]

mat.en′sis. N.L. masc. adj. *matensis* of or belonging to mat (of uncertain derivation).

Spore chains in Section *Spirales*. Open spirals are the dominant forms; spore chains suggesting primitive spirals of *Retinaculiaperti* cultures or flexuous chains of *Rectiflexibiles* are also present. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny. Spines are short and inconspicuous; some smooth spores may be seen.

Color of colony: mature aerial mass color in the Gray color series (color tab 3ge, light grayish yellowish brown; to 5fe light grayish reddish brown) on salts-starch agar; Gray or White color series on yeast-malt agar and glycerol-asparagine agar. One observer reports tab 5dc (grayish yellowish pink) from the Red color series for growth on yeast-malt agar, oatmeal agar, and salts-starch agar. This trace of red (or violet) pigment in aerial color is also noted in the original description (Margalith et al., 1959). Reverse side of colony with red pigments in mycelium which modify characteristic substrate colors to dark reddish brown on yeast-malt agar and salts-starch agar; light grayish brown or yellowish pink on oatmeal agar and glycerol-asparagine agar. The substrate mycelium pigment is not a strong pH indicator (one observer reports change from violet to pink with addition of 0.05 M HCl).

Color in medium: melanoid pigments are not found in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red or violet pigments are found in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. One observer reports a change from violet to red by addition of 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on raffinose. Utilization of sucrose is doubtful.

Type strain shows the highest sequence similarity to: *S. althioticus*, AY999808, 99.8%; *S. griseorubens*, AB184139, 99.7%; *S. labedae*, AB184704, 99.6%; *S. variabilis*, DQ442551, 99.6%; *S. griseoincarnatus*, AJ781328, 99.6%; *S. paradoxus*, AB184628, 99.6%; *S. erythrogriseus*, AJ781328, 99.6%; *S. griseoflavus*, AJ781322, 99.5%; *S. violaceorubidus*, AJ781374, 99.4%; *S. viridochromogenes*, DQ442555, 99.3%; *S. albaduncus*, AY999757, 99.3%; *S. lusitanus*, AB184424, 99.3%; *S. malachitofuscus*, AB184282, 99.3%; *S. coerulescens*, AY999720, 99.2%; *S. heliomycini*, AB184712, 99.2%; *S. glaucescens*, AB184843, 99.2%; *S. tendae*, D63873, 99.2%; *S. capillispiralis*, AB184577, 99.2%; *S. gancidicus*, AB184660, 99.2%; *S. pseudogriseolus*, DQ442541, 99.2%; *S. griseoloalbus*, AB184275, 99.2%; *S. bellus*, AB184849, 99.2%; *S. collinus*, AB184123, 99.2%; *S. lienomycini*, AJ781353, 99.1%; *S. violaceochromogenes*, AY999867, 99.1%; *S. flaveolus*, AB184764, 99.1%; *S. cellulosae*, DQ442495, 99.1%; *S. longispororuber*, AB184440, 99%; *S. rubrogriseus*, AB184681, 99%; *S. ambofaciens*, M27245, 99%; *S. diastaticus* subsp. *diastaticus*, AB184785, 99%; *S. gougerotii*, AB184742, 99%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 99%; *S. azureus*, EF178674, 99%; *S. lomondensis*, AB184673, 99%; *S. fragilis*, AY999917, 99%; *S. intermedius*, AB184277, 99%; *S. misionensis*, EF178678, 99%.

Sequence accession no. (16S rRNA gene): AB184532.

313. **Streptomyces mediolani** Bianchi, Grein, Julita, Marnati and Spalla 1970, 243[AL]

me.di.o.la′ni. L. n. *Mediolanum* Milan; L. gen. adj. *mediolani* of Milan.

Sporophores are long and straight; from these, through monopodial branching, the spore bearing hyphae originate as long, straight to slightly flexuous filaments. Spores are cylindrical in shape, and devoid of any ornamentation. Growth is always very good on most common agar media; the substrate mycelium grows as a compact, smooth patina, showing a yolk-yellow to orange-yellow color. The aerial mycelium is very abundant showing a velvety to dusty aspect; its color varies from yellow-vanilla to yellow-rose or yellow-beige, according to the different substrates on which it is grown.

The spore suspension prepared from a culture of *S. mediolani* grown on a solid medium containing yeast extract, glucose, and inorganic salts, was used to inoculate 300 ml Erlenmeyer flasks each containing 60 ml liquid medium having dextrin, casein, corn-steep liquor, calcium carbonate and other inorganic salts as ingredients. After 27 h of incubation at 28°C on a rotary shaker, aliquots of the culture were transferred to 300 ml Erlenmeyer flasks each containing 30 ml of the following production medium: soluble starch, 37.5 g; morsuit (a maltose-rich syrup manufactured by F.R.A.G.D., Italy), 33 g; soybean meal 40 g; NaCl, 1.25 g; KH_2PO_2, 3 g; $MgSO_4{\cdot}7H_2O$, 0.5 g; $CaCO_3$, 3.5 g; $(NH_4)_2SO_4$, 1.5 g; $ZnSO_4{\cdot}7H_2O$, 0.005 g; $FeSO_4{\cdot}7H_2O$, 0.005 g; $CuSO_4{\cdot}5H_2O$, 0.001 g; tap water up to 1000 ml. The flasks were incubated for 8 d on a rotary shaker at 29°C.

The extracts prepared from the mycelium of *S. mediolani* with the aid of different organic solvents contained three main carotenoids, designated A, B, and C, together with other minor pigments. Compounds A and B were epiphasic, while pigment C precipitated at the interfaces in the biphasic system petroleum ether (b.p. 40–60°C)/90% aqueous methanol. Separation of the epiphasic pigments by chromatography on aluminium oxide, using petroleum ether containing increasing amounts of acetone as developing agent, allowed isolation of pigment A [$C_{40}H_{48}$, red crystals m.p. 200–201°C, λ_{max} (petroleum ether) 278, 428 (inflexion), 448, 478 nm] and pigment B [amorphous red power, m.p. 180–185°C, λ_{max} (petroleum ether) 278, 340 (*cis*-peak), 425 (inflexion), 446, 472 nm]. Pigment C was purified by chromatography on silicic acid using 10% acetone in benzene as developing solvent and isolated as a dark-red amorphous solid [m.p. 200°C (dec), λ_{max} (petroleum ether) 278, 340 (*cis*-peak), 425 (inflexion), 445, 475 nm].

Pigment A proved to be identical to isorenieratene (i) by direct comparison with an authentic sample. Pigments C and B were soluble in ethanolic potassium hydroxide and showed a hydroxyl band in the IR at 3590 cm^{-1} (methylene chloride solution). On treatment with acetic anhydride and pyridine, pigments B and C were converted to a monoacetate ($C_{42}H_{50}O_2$, m.p. 156–158°C) and a diacetate ($C_{44}H_{52}O_4$, m.p. 182–184°C), respectively, both derivatives showing UV and visible spectra identical to those displayed by I (no *cis*-peak), and a phenolic acetate band at 1758 cm^{-1} in the IR (KBr pellets). Treatment of the acetyl derivative of pigment B with chromic anhydride in benzene-acetic acid gave crocetindial, 2,3,6-trimethylbenzaldehyde, and 2,3,6-trimethyl-4-acetoxybenzaldehyde, as main breakdown products. All compounds were identified by direct comparison (UV, visible, and IR-spectra, mixed m.p., chromatographic behavior) with authentic samples prepared by synthesis. Similarly, oxidation of the diacetyl derivative of pigment C gave crocetindial and 2,3,6-trimethyl-4-acetoxybenzaldehyde as major reaction products. Structures II and III could therefore be written for pigments B and C.

The new carotenoids B (3-hydroxyisorenieratene) and C (3,3′-dihydroxyisorenieratene) have been subsequently prepared by chemical synthesis. The Wittig reaction of crocetindial with triphenyl-2,3,6-trimethylbenzylphosphonium bromide and triphenyl-[2,3,6-trimethyl-4-(2′-tetrahydropyranyloxy)]-benzylphosphonium bromide as reagents was used. For the preparation of the latter reagent, 2,3,6-trimethyl-4-hydroxybenzaldehyde was converted to the 4-(2′-tetrahydopyranyloxy) derivative, then reduced with lithium aluminium hydride to 2,3,6-trimethyl-4-(2′-tetrahydropyranyloxy)-benzylalcohol (m.p. 85°C), which was in turn converted to the phosphonium bromide by the usual procedure. When crocetindial was allowed to react with triphenyl-2,3,6-trimethyl-4-(2′-tetrahydropyranyloxy)-benzylphosphonium bromide in the presence of *n*-butyl lithium, symmetric 3,3′-ditetrahydropyranyloxyisorenieratene, $C_{50}H_{64}O_4$ (m.p. 185–187°C), was obtained. Removal of the protecting group by acid treatment afforded III (overall yield 60%). When the Wittig reaction was repeated starting with a mixture of both phosphonium bromides, a product was obtained from which, after removal of the tetrahydropyranyl group, 3-hydoxy-isorenieratene (II) was isolated in 30% yield, together with lower amounts of I and III. The synthetic compounds II and II displayed the same visible and IR-spectra, and identical chromatographic behavior, also after acetylation, as natural pigments B and C.

The peptide antibiotic histidomycin was isolated from the filtered broth by absorption-elution on ion exchange resins followed by molecular sieves fractionation. The identification of the antibiotic was performed on the basis of its chemical and biological properties, and of direct comparison with an authentic sample. The substance was responsible for the anti-bacterial activity displayed by culture liquids of *S. mediolani.*

Type strain shows the highest sequence similarity to: *S. sindenensis*, AB184759, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. albovinaceus*, AB249958, 100%; *S. griseoplanus*, AY999894, 100%; *S. anulatus*, DQ026637, 100%; *S. globisporus* subsp. *globisporus*, EF178686, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. praecox*, AB184293, 100%; *S. flavofuscus*, AB249935, 100%; *S. fimicarius*, AY999784, 100%; *S. badius*, AY999783, 100%; *S. griseinus*,

314. **Streptomyces megasporus** (*ex* Krasil'nikov, Agre, Dorokhova and Sokolov 1968) Agre 1986, 575[VP] (Effective publication: Agre *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces megasporus*" Krasil'nikov, Agre, Dorokhova and Sokolov 1968)

me.ga.spo′rus. Gr. adj. *megas* big; Gr. n. *spora* seed; N.L. masc. adj. *megasporus* large spored.

Spore chains are spirals (*Spirales*); spores have spines and warts. On mineral agar 1: aerial mycelium is pale green-gray; substrate mycelium is colorless; no diffusible pigment. On glycerol-nitrate agar and oatmeal agar: aerial mycelium is white or absent; substrate mycelium is colorless; no diffusible pigment. On starch-ammonia agar: poor growth; aerial mycelium is poor, grayish; substrate mycelium is colorless; no diffusible pigment. On glycerol-asparagine agar: poor growth; aerial mycelium is white; substrate mycelium is colorless; no diffusible pigment. On organic agar 2: aerial mycelium absent; substrate mycelium colorless or yellow; no diffusible pigment. Melanoid pigments are not formed. Growth on glucose, maltose, xylose, rhamnose, and arabinose.

Type strain shows no sequence similarity over 99%.

315. **Streptomyces melanogenes** Sugawara and Onuma 1957, 141[AL]

me.la.no′ge.nes. Gr. adj. *melas* black; N.L. suff. -*genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *melanogenes* producing black.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are long with 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5cb, grayish yellowish pink) on oatmeal agar and salts-starch agar; White or Gray color series on yeast-malt agar and salts-starch agar. Reverse side of colony is grayed yellow to yellow-brown is usually modified by red (becoming dark brown to reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Reports vary on utilization of sucrose. No growth or only traces of growth rhamnose.

Type strain shows the highest sequence similarity to: *S. noboritoensis*, AB184287, 100%; *S. crystallinus*, AB184652, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Sequence accession no. (16S rRNA gene): AB184222.

316. **Streptomyces melanosporofaciens** Arcamone, Bertazzoli, Ghione and Scotti 1959, 215[AL]

me.la.no.spo.ro.fa′ci.ens. Gr. adj. *melas* black; N.L. n. *spora* a spore; L. part. adj. *faciens* producing; N.L. part. adj. *melanosporofaciens* black spore producing.

Spore chains in Section *Spirales*, but spore chain morphology is sometimes difficult to observe because of accumulations of moist exudate ("hygroscopic" masses) on the sporulating surfaces. Identifiable spore chains are often short with only 3–10 spores per chain and may form loops or incomplete spirals as well as true spirals. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth, or with unevenly ridged surface suggesting warty spores on some preparations. In 7–21 d, sporulating surfaces form globose accumulations of liquid exudate. These coalesce and may eventually give rise to a moist black surface containing loose spores.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar and oatmeal agar; poorly sporulating cultures on salts-starch agar and glycerol-asparagine agar may appear to be in the Yellow color series. Areas of sporulation are usually gray at first, but may become

moist-black as spore masses coalesce in a liquid exudate on the aerial mycelium. Reverse side of colony is dark grayish yellow to orange-yellow on yeast-malt agar; light yellow to light grayish olive on oatmeal agar; nearly colorless to strong yellow on salts-starch agar and glycerol-asparagine agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth, but a reddish brown, rose, or yellow non-melanoid pigment may be found in tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. Only traces of growth are found with sucrose.

Type strain shows the highest sequence similarity to: *S. sporoclivatus*, AB249934, 99.6%; *S. antimycoticus*, AB184185, 99.6%; *S. rutgersensis* subsp. *castelarensis*, AY508511, 99.4%; *S. geldanamycininus*, DQ334781, 99%.

Sequence accession no. (16S rRNA gene): AJ271887.

317. **Streptomyces mexicanus** Petrosyan, García-Varela, Luz-Madrigal, Huitrón and Flores 2003, 272[VP]

mex.i.ca'nus. N.L. masc. adj. *mexicanus* of or belonging to Mexico, the source of the soil from which the organism was isolated.

Forms highly branched substrate mycelium and aerial hyphae which differentiate into long *Rectiflexibiles* chains of 10 or more, green, smooth spores. Spores are spherical, about 0.88 μm in diameter, or slightly oval. Aerial spore mass color is gray with a slight green tint. Substrate mycelium is beige on standard media. Yellowish diffusible pigments are formed on yeast-extract, malt-extract, and oatmeal agar. Melanin pigments are not produced on peptone-iron or tyrosine agars. Positive for H_2S production. Degrades arbutin, starch, xylan, adenine, casein, hypoxanthine, and L-tyrosine, but not guanine or testosterone. Utilizes L-arabinose, fructose, glucose, raffinose, mannitol, mannose, xylose, galactose, maltose, glycerol, lactose, cellobiose, trehalose, and sodium acetate as sole carbon sources, but not *myo*-inositol, melezitose, L-rhamnose, sorbitol, or sucrose. Growth occurs between 20 and 55°C, from pH 4.3–8.0, and in the presence of 6% (w/v) NaCl and ampicillin (100 μg/ml). Growth is inhibited in the presence of chloramphenicol, erythromycin, gentamicin, nalidixic acid sodium salt, kanamycin sulfate, rifampin, tetracycline hydrochloride, and thiostrepton, and in the presence of 7% (w/v) NaCl. No antimicrobial activity is shown against *Escherichia coli* JM 109 or against representative strains of *Aspergillus flavipes*, *Aureobasidium* sp., *Bacillus subtilis*, *Pichia pastoris*, "*Sarcina lutea*", or *Trichoderma viridae*.

Type strain shows the highest sequence similarity to: *S. thermoviolaceus* subsp. *apingens*, Z68095, 99%.

Source: isolated from a soil sample obtained at a sugarcane field in the State of Morelos, Mexico.

DNA G+C content (mol%): not known.

Type strain: CH-M-1035, BM-B-384, DSM 41796, JCM 12681, NBRC 100915, NRRL B-24196.

Sequence accession no. (16S rRNA gene): AB249966.

318. **Streptomyces michiganensis** Corbaz, Ettlinger, Keller-Schierlein and Zähner 1957b, 205[AL]

mi.chi.gan.en'sis. N.L. masc. adj. *michiganensis* of or belonging to Michigan, the source of the soil from which the organism was isolated.

Spore chain morphology in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (colorless or characteristic grayed yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast broth. Yellow pigment found in medium in yeast-malt agar and oatmeal agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH of HCl.

D-Glucose, D-xylose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on L-arabinose, sucrose, and rhamnose. Variable reports on growth with raffinose.

Type strain shows the highest sequence similarity to: *S. xanthochromogenes*, DQ442559, 100%; *S. mauvecolor*, AB184532, 99.4%.

Source: isolated from soil from Michigan.

DNA G+C content (mol%): not known.

Type strain: ATCC 14970, ATCC 19786, CBS 538.68, BCRC 11613, DSM 40015, NBRC 12797, JCM 4594, NRRL B-1940, NRRL-ISP 5015, RIA 1065, UNIQEM 172, VKM Ac-862.

Sequence accession no. (16S rRNA gene): AB184153.

319. **Streptomyces microflavus** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 950[AL] ("*Actinomyces microflavus*" Krainsky 1914, 686; "*Micromonospora microflava*" Duché 1934, 29)

mic.ro.fla'vus. Gr. adj. *mikros* small; L. adj. *flavus* yellow; N.L. masc. adj. *microflavus* small, yellow.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or Yellow color series (2dc, yellowish gray; 2db, pale yellow) on yeast-malt agar and oatmeal agar; Yellow color series (2ba or 2db, pale yellow) on salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow to yellowish brown, olive brown or

strong brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on the utilization of sucrose. Utilization of L-arabinose is doubtful. No growth or only traces of growth with iso-inositol and raffinose.

Type strain shows the highest sequence similarity to: *S. fulvorobeus*, AB184711, 100%; *S. lipmanii*, AB184148, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. alboviridis*, AB184256, 100%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.9%; *S. flavofuscus*, AB249935, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. fimicarius*, AY999784, 99.9%; *S. griseoplanus*, AY999894, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. floridae*, AB184656, 99.9%; *S. praecox*, AB184293, 99.9%; *S. anulatus*, DQ026637, 99.8%; *S. luridiscabiei*, AF361784, 99.8%; *S. pluricolorescens*, DQ442540, 99.8%; *S. acrimycini*, AY999889, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. griseinus*, AB184205, 99.8%; *S. badius*, AY999783, 99.8%; *S. rubiginosohelvolus*, AB184240, 99.8%; *S. sindenensis*, AB184759, 99.8%; *S. mediolani*, AB184674, 99.8%; *S. californicus*, AB184755, 99.8%; *S. parvus*, DQ442537, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. globisporus* subsp. *globisporus*, EF178686, 99.7%; *S. albovinaceus*, AB249958, 99.7%; *S. flavovirens*, DQ026635, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. flavogriseus*, AJ494864, 99.5%; *S. yanii*, AB006159, 99.4%; *S. atroolivaceus*, AJ781320, 99.4%; *S. olivoviridis*, AB184227, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. pulveraceus*, AB184806, 99.4%; *S. celluloflavus*, AB184476, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. nitrosporeus*, EF178680, 99.3%; *S. spiroverticillatus*, AB184814, 99.2%; *S. sanglieri*, AB249945, 99.2%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. atratus*, DQ026638, 99.1%; *S. mutomycini*, AB249951, 99.1%; *S. candidus*, DQ026663, 99.1%; *S. gelaticus*, DQ026636, 99.1%; *S. cremeus*, AB184124, 99%.

Sequence accession no. (16S rRNA gene): DQ445795.

Further comments: according to Lanoot et al. (2005b), *Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948 emend. Lanoot et al. 2005b is an earlier heterotypic synonym of *Streptomyces griseus* subsp. *alpha* (Ciferri 1927) Pridham 1970, an earlier heterotypic synonym of *Streptomyces griseus* subsp. *cretosus* Pridham 1970[AL], an earlier heterotypic synonym of *Streptomyces lipmanii* (Waksman and Curtis 1916) Waksman and Henrici 1948, and an earlier heterotypic synonym of *Streptomyces willmorei* (Erikson 1935) Waksman and Henrici 1948.

320. **Streptomyces minutiscleroticus** (Thirumalachar *in* Thirumalachar, Rahlkar, Desmukh and Sukapure 1965) Pridham 1970, 41[AL] emend. Lanoot, Vancanneyt, van Schoor, Liu and Swings 2005b, 731 (*Chainia minutisclerotica* Thirumalachar *in* Thirumalachar, Rahlkar, Desmukh and Sukapure 1965, 7)

mi.nu.ti.scle.ro′ti.cus. L. masc. adj. *minutus* little, small, minute; N.L. n. *sclerotium* sclerotium; L. masc. suff. *-icus* suffix used in adjectives with the sense of belonging to; N.L. masc. adj. *minutiscleroticus* belonging to a small sclerotium.

Spore chains in Section *Spirales*. Mature spore chains generally contain 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Special morphological characteristics: sclerotic granules are produced. Minute sclerotic granules are produced on broad hyphae, often on the agar surface or vegetative substrate. One observer compares these small sclerotia to actinosporangium-like formations, on oatmeal agar and salts-starch agar. Sclerotic granules are reported on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar in 7–21 d.

Color of colony: aerial mass color in the Gray or Yellow color series (2dc, yellowish gray; 24½dc, pale yellow green; or 2ba, pale yellow) on yeast-malt agar and salts-starch agar; Yellow color series (2ba, pale yellow) on oatmeal agar and glycerol-asparagine agar. Reverse side of colony is strong brown on yeast-malt agar; grayish yellow to orange yellow or brown on oatmeal agar and salts-starch agar; yellowish brown, orange yellow or reddish brown on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Some yellow pigment may or may not be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When present, this pigment is not pH-sensitive.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with sucrose or raffinose.

Type strain shows the highest sequence similarity to: *S. vinaceusdrappus*, AY999929, 100%; *S. geysiriensis*, DQ442501, 100%; *S. plicatus*, AB184291, 100%; *S. ghanaensis*, AY999851, 100%; *S. rochei*, AB184237, 100%; *S. mutabilis*, EF178679, 99.8%; *S. tuirus*, AB184690, 99.5%; *S. djakartensis*, AB184657, 99.5%; *S. anandii*, AB184402, 99.3%; *S. violaceorubidus*, AJ781374, 99.3%; *S. pilosus*, AB184161, 99.2%; *S. flavoviridis*, AB184842, 99.2%; *S. calvus*, AB184329, 99.1%; *S. tendae*, D63873, 99.1%; *S. azureus*, EF178674, 99.1%; *S. asterosporus*, AB184706, 99.1%; *S. levis*, AB184670, 99%; *S. luteogriseus*, AB184379, 99%; *S. aureorectus*, AB184710, 99%; *S. capillispiralis*, AB184577, 99%; *S. pseudogriseolus*, DQ442541, 99%; *S. naganishii*, DQ442529, 99%; *S. virens*, DQ442554, 99%; *S. gancidicus*, AB184660, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 17757, ATCC 19346, CBS 231.65, CBS 662.72, BCRC 12544, CMI 112786, DSM 40301, NBRC

13000, NBRC 13361, JCM 3102, JCM 4790, KCTC 9123, LMG 20062, NCIMB 10996, NRRL B-12202, NRRL-ISP 5301, PCM 2304, RIA 1322, RIA 885.

Sequence accession no. (16S rRNA gene): EF178696.

Further comments: Streptomyces minutiscleroticus (Thirumalachar 1965) Pridham 1970 and *Chainia minutisclerotica* Thirumalachar et al. (1965) have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b (1) of the Bacteriological Code].

According to Lanoot et al. (2005b), *Streptomyces minutiscleroticus* (Thirumalachar 1965) Pridham 1970 emend. Lanoot et al. 2005b is an earlier heterotypic synonym of *Streptomyces flaviscleroticus* (*ex* Pridham 1970) Goodfellow et al. 1986a.

321. **Streptomyces mirabilis** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Ruschmann 1952, 543[AL] ("*Actinomyces mirabilis*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 107)

mi.ra'bi.lis. L. masc. adj. *mirabilis* marvellous.

Spore chains in Section *Spirales*. Sterile hyphae may be abundant; these are often flexuous or hooked. Mature spore chains are moderately long, sometimes with more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but sporulation may be poor, especially on yeast-malt agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (2fe, medium gray; 3fe, light brownish gray; also 3ig, 4ig, 3li, grayish brown and brownish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayish yellow becoming moderate olive brown to dark olive or dark brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; grayish blue or grayish green and moderate yellowish brown on yeast-malt agar. Substrate pigment is not a pH indicator or is modified only slightly from olive brown to dark brown by 0.05 M NaOH on oatmeal agar and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and in trace amounts in tryptone-yeast broth but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on utilization of D-xylose. No growth or only traces of growth with sucrose or raffinose.

Type strain shows the highest sequence similarity to: *S. olivochromogenes*, AY094370, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27447, CBS 751.72, DSM 40553, NBRC 13450, JCM 4551, JCM 4791, NRRL B-2400, NRRL-ISP 5553, RIA 1411.

Sequence accession no. (16S rRNA gene): AB184412.

322. **Streptomyces misakiensis** Nakamura 1961, 86[AL]

mi.sa.ki.en'sis. N.L. masc. adj. *misakiensis* of or belonging to Misaki, referring to Misakicho, Kanagawa Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long with 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on salts-starch agar and glycerol-asparagine agar; Gray or Red color series on yeast-malt agar and oatmeal agar. The most representative color tab from the Gray color-wheel is 2dc (yellowish gray) for all ISP media. One observer selected tab 5dc (grayish yellowish pink) from the Red color-wheel as the most representative color on yeast-malt agar and oatmeal agar. Reverse side of colony is yellow to yellow-brown is modified by red, becoming brown to strong brown on yeast-malt agar, salts-starch agar and glycerol-asparagine agar and orange to light brown on oatmeal agar; this pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red pigment is found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 NaOH or HCl.

D-Glucose, sucrose, D-fructose, and raffinose are utilized for growth. No growth or only trace of growth with L-arabinose, D-xylose, iso-inositol, D-mannitol and rhamnose. In the original description (Nakamura, 1961), L-arabinose and D-mannitol were also reported as supporting growth with Czapek's agar as basal medium.

Type strain shows the highest sequence similarity to: *S. catenulae*, AJ621613, 100%; *S. libani* subsp. *libani*, AB184414, 99.6%; *S. nigrescens*, DQ442530, 99.5%; *S. tubercidicus*, AJ621612, 99.5%; *S. caniferus*, AB184640, 99.4%; *S. libani* subsp. *rufus*, AJ781351, 99.3%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.3%; *S. platensis*, AB045882, 99.2%; *S. sioyaensis*, DQ026654, 99.2%; *S. ramulosus*, DQ026662, 99.1%.

Source: isolated from soil from Misakicho, Kanagawa Prefecture, Japan.

DNA G+C content (mol%): not known.

Type strain: AS 4.1437, ATCC 23938, CBS 278.65, CBS 922.68, DSM 40222, IFM 1195, NBRC 12891, JCM 4062, JCM 4653, NCIMB 9852, NRRL B-2923, NRRL-ISP 5222, RIA 1166, VKM Ac-625.

Sequence accession no. (16S rRNA gene): AB217605.

323. **Streptomyces misionensis** Cercós, Eilberg, Goyena, Souto, Vautier and Widuczynski 1962, 22[AL]

mi.si.on.en'sis. N.L. masc. adj. *misionensis* of or belonging to Misiones, a province in Argentina, South America, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*. Mature spore chains are moderately long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal

agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth or slightly warty.

Color of colony: aerial mass color in the Gray or Red color series (4ig, light grayish brown in Gray series or 4ge, light grayish reddish brown in the Red series) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is olive brown to moderate orange on yeast-malt agar; grayish yellow, yellowish brown, or olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Utilization of iso-inositol, rhamnose, sucrose and raffinose is doubtful.

Type strain shows the highest sequence similarity to: *S. phaeoluteichromatogenes*, AJ391814, 99.8%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 99.2%; *S. gougerotii*, AB184742, 99.2%; *S. diastaticus* subsp. *diastaticus*, AB184785, 99.2%; *S. levis*, AB184670, 99.1%; *S. paradoxus*, AB184628, 99.1%; *S. glaucescens*, AB184843, 99%; *S. matensis*, AB184221, 99%; *S. intermedius*, AB184277, 99%.

Source: isolated from soil from Misiones, a province in Argentina, South America.

DNA G+C content (mol%): not known.

Type strain: ATCC 14991, ATCC 25475, CBS 885.69, BCRC 12094, DSM 40306, NBRC 13063, JCM 4497, NRRL B-3230, NRRL-ISP 5306, RIA 1255, VKM Ac-626.

Sequence accession no. (16S rRNA gene): EF178678.

324. **Streptomyces mobaraensis** (Nagatsu and Suzuki 1963) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptomyces mobaraensis* Nagatsu and Suzuki 1963, 47; *Streptoverticillium mobaraense* Locci, Baldacci and Petrolini Baldan 1969, 42)

mo.ba.ra.en′sis. N.L. masc. adj. *mobaraensis* of or belonging to Mobara (named after the place of origin, Mobara City, Chiba Prefecture, Japan).

Good growth on potato-glucose agar (Baldacci et al., 1954). Color: reverse light beige to greenish yellow; aerial mycelium dirty white with greenish shades to greenish gray. On Bacto Czapek agar and Casamino acids-Czapek agar (1 g/l Difco vitamin-free Casamino acids, replacing sodium nitrate): very poor growth; colorless; traces only of off-white aerial mycelium. On glucose-asparagine agar (ISP medium 5 with 1% glucose replacing glycerol): good growth; color, reverse yellowish; aerial mycelium whitish. On glycerol-asparagine agar: good growth; color, reverse beige to light brown to yellowish brown; aerial mycelium white to off-white beige. On inorganic salts-starch agar: good growth; color, reverse brown-yellowish to dirty greenish yellow; aerial mycelium beige to dirty greenish beige. On yeast extract-malt extract agar: good growth; color: reverse brown-yellow; aerial mycelium white to dirty beige. On Bacto Emerson agar: good growth; color: reverse yellowish; aerial mycelium off-white. On Bennett agar (1% glucose, 0.1% Bacto beef agar, 0.1% yeast extract, 0.2% peptone, 1.5% agar): good growth; color, reverse yellow; aerial mycelium white with pale pink shades in patches. On Oxoid nutrient agar: good growth; color, reverse yellowish; poor, white aerial mycelium.

Grows at 27°C as well as at 37°C. There are also no differences in the amount of aerial mycelium, which is greener in color at 37°C. Greenish shades of the reverse are also more accentuated. No growth at 45°C. The type strain produces piericidin A, piericidin B, and detoxin and exhibits anti-bacterial activity.

Type strain shows the highest sequence similarity to: *S. sapporonensis*, AB184508, 99.1%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 29032, CBS 199.75, BCRC 12165, DSM 40847, NBRC 13819, JCM 4168, NCIMB 11159, NRRL B-3729, RIA 1627, VKM Ac-928.

Sequence accession no. (16S rRNA gene): DQ442528.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces mobaraensis* is proposed as a *nomen revictum* (basonym: "*Streptomyces mobaraensis*" Kubo et al. (1964).

According to Labeda (1996), *Streptomyces mobaraensis* (Nagatsu and Suzuki 1963) Witt and Stackebrandt 1991 is an earlier synonym of *Streptomyces ladakanum* (Hanka et al. 1966) Witt and Stackebrandt 1991.

According to Hatano et al. (2003), *Streptomyces mobaraensis* (Nagatsu and Suzuki 1963) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces ladakanum* (Hanka et al. 1966) Witt and Stackebrandt 1991.

325. **Streptomyces monomycini** Gause and Terekhova 1986a, 575[VP] (Effective publication: Gause and Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

mo.no.my.ci′ni. N.L. n. *monomycinum* monomycin; N.L. gen. n. *monomycini* of monomycin, intended to mean monomycin producing.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: aerial mycelium is white, poor; substrate mycelium is colorless to greenish-gray-brownish; no diffusible pigment. On starch-ammonia agar: no aerial mycelium; colorless substrate mycelium; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is white; substrate mycelium is gray-brownish-yellow to green-gray-brownish; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is light gray; substrate mycelium is colorless; no diffusible pigment. On oatmeal agar: aerial mycelium is poorly developed, white; substrate mycelium is greenish yellow; no diffusible pigment. On organic agar 2: aerial mycelium is poorly developed, white; substrate mycelium is gray-brownish yellow to green-gray-brownish; diffusible pigment is absent or weak, colors are similar to substrate mycelium. Melanoid pigments are not formed. Growth on fructose, glucose, xylose, and mannitol, no growth on sucrose, rhamnose, inositol, raffinose, and arabinose. Antibiotic: monomycin.

Type strain shows the highest sequence similarity to: *S. ochraceiscleroticus*, AB184094, 99.5%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.4%; *S. niger*, AJ621607,

99.4%; *S. erumpens*, AJ621603, 99.4%; *S. olivaceiscleroticus*, AJ621606, 99.4%; S. *violens*, AJ621605, 99.3%; *S. purpurogeneiscleroticus*, AJ621604, 99.3%; *S. rimosus* subsp. *rimosus*, AB045883, 99.1%; *S. platensis*, AB045882, 99%; *S. sioyaensis*, DQ026654, 99%; *S. libani* subsp. *rufus*, AJ781351, 99%; *S. caniferus*, AB184640, 99%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 41801, INA 1465, JCM 9768, NBRC 100769, NRRL B-24309.

Sequence accession no. (16S rRNA gene): DQ445790.

326. **Streptomyces morookaense** (Locci 1985) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces moro-okaensis*" Niida, Hamamoto, Tsuruoka and Hara 1963; "*Streptoverticillium moro-okaense*" Arai 1976; "*Streptoverticillium morookaense*" Locci 1985, 232)

mo.ro.ok.a.en′se. N.L. adj. *morookaense* (*sic*) of or belonging to Moro-oka (possibly the isolation place).

Spore chains in Section *Verticillati*; mature spore chains are predominantly umbellate monoverticillate (biverticillate). Mature spore chains are moderately long, often with more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (1dc, 1cb, 1½ec, pale yellow green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale yellow to pale greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Utilization of rhamnose is doubtful. No growth or only traces of growth with L-arabinose, sucrose, or D-xylose.

Type strain shows the highest sequence similarity to: *S. lavenduligriseus*, DQ442515, 99.6%; *S. thioluteus*, AB184753, 99.5%; *S. abikoensis*, AB184537, 99.1%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19166, CBS 717.72, DSM 40503, NBRC 13416, JCM 4673, JCM 4793, NRRL B-12429, NRRL-ISP 55036, RIA 1377, VKM Ac-1916.

Sequence accession no. (16S rRNA gene): AJ781349.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces morookaense* is proposed as a *nomen revictum* (basonym: "*Streptomyces morookaense*" Niida et al. 1963).

According to Hatano et al. (2003), *Streptomyces morookaense* (Locci and Schofield 1989) Witt and Stackebrandt 1991 is a heterotypic synonym of "*Streptomyces aspergilloides*" (NBRC 13461).

327. **Streptomyces murinus** Frommer 1959, 198[AL]

mu.ri′nus. L. masc. adj. *murinus* of mice, mouse-gray; referred to as reddish-gray in original description.

Spore chains in Section *Spirales*. Mature spore chains generally 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Air-dried preparation for electron microscopy may show internal contractions that suggest a warty appearance.

Color of colony: aerial mass color in the Red color series on glycerol-asparagine agar; Gray series on salts-starch agar; Gray or Red color series on oatmeal agar and glycerol-asparagine agar. Reverse side of colony is grayed yellow on oatmeal agar and glycerol-asparagine agar; grayed yellow or yellow modified by red on yeast-malt and salts-starch agar. Substrate pigment is not a pH indicator.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on L-arabinose, sucrose, rhamnose, and raffinose. Variable reports on growth with iso-inositol.

Type strain shows the highest sequence similarity to: *S. griseofuscus*, AB184206, 100%; *S. costaricanus*, AB249939, 100%; *S. phaeogriseichromatogenes*, AJ391813, 99.6%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19788, CBS 540.68, BCRC 12061, CECT 3309, DSM 40091, NBRC 12799, NBRC 14802, JCM 4333, JCM 4595, KCTC 9492, LMG 10475, NCIMB 12701, NRRL B-2286, NRRL-ISP 5091, PCM 2369, RIA 1067, UNIQEM 174, VKM Ac-1190.

Sequence accession no. (16S rRNA gene): AB184155.

328. **Streptomyces mutabilis** (Preobrazhenskaya and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 69[AL] ("*Actinomyces mutabilis*" Preobrazhenskaya and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 166)

mu.ta′bi.lis. L. masc. adj. *mutabilis* changeable, so named because the organism could not be assigned to any of the species known in the literature.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Spore chains are poorly developed so that hooks, loops, or partial spirals are shorter and of smaller diameter than on typical *Retinaculiaperti* cultures. Spirals, when found, are aberrant. Mature spore chains generally contain only 3–10 spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or White color series on yeast-malt agar and oatmeal agar; White series on salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigments found in medium, except for traces of yellow or greenish yellow pigments in yeast-malt agar.

This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Some growth occurs with sucrose as the carbon source; raffinose is not utilized.

Type strain shows the highest sequence similarity to: *S. rochei*, AB184237, 99.9%; *S. vinaceusdrappus*, AY999929, 99.9%; *S. plicatus*, AB184291, 99.9%; *S. geysiriensis*, DQ442501, 99.8%; *S. ghanaensis*, AY999851, 99.8%; *S. minutiscleroticus*, EF178696, 99.8%; *S. tuirus*, AB184690, 99.6%; *S. djakartensis*, AB184657, 99.4%; *S. violaceorubidus*, AJ781374, 99.2%; *S. flavoviridis*, AB184842, 99.1%; *S. anandii*, AB184402, 99.1%; *S. levis*, AB184670, 99.1%; *S. tendae*, D63873, 99.1%; *S. violaceus*, AB184315, 99.1%; *S. pilosus*, AB184161, 99.1%; *S. luteogriseus*, AB184379, 99.1%; *S. azureus*, EF178674, 99.1%; *S. janthinus*, AB184851, 99.1%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.1%; *S. capillispiralis*, AB184577, 99%; *S. roseoviolaceus*, AJ399484, 99%; *S. rubrogriseus*, AB184681, 99%; *S. asterosporus*, AB184706, 99%; *S. africanus*, AY208912, 99%; *S. calvus*, AB184329, 99%.

Sequence accession no. (16S rRNA gene): EF178679.

329. **Streptomyces mutomycini** Gause and Maximova 1986a, 575[VP] (Effective publication: Gause and Maximova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

mu.to.my.ci'ni. N.L. n. *mutomycinum* mutomycin; N.L. gen. n. *mutomycini* of mutomycin, intended to mean mutomycin producing.

Spore chains are spiral (*Spirales*); spores are spiny, spines are short. On mineral agar 1 and oatmeal agar: aerial mycelium is gray to dark gray; substrate mycelium is colorless, sometimes with gray spots; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is poor, gray; substrate mycelium and diffusible pigment are yellow-brown. On starch-ammonia agar: poor, gray aerial mycelium; colorless substrate mycelium; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium and diffusible pigment are gray, poor; substrate mycelium is colorless or pinkish gray to yellow-brown. On organic agar 2: no aerial mycelium: substrate mycelium and diffusible pigment are dark yellow or olive-gray. On organic agar 79: no aerial mycelium; substrate mycelium and diffusible pigment are brown. Melanoid pigments are not formed. Moderate growth on sugar and sucrose, fructose, glucose, and mannitol; poor growth on arabinose and xylose. Antibiotic: mutomycin.

Type strain shows the highest sequence similarity to: *S. clavifer*, DQ026670, 99.8%; *S. olivoviridis*, AB184227, 99.7%; *S. atroolivaceus*, AJ781320, 99.7%; *S. finlayi*, AY999788, 99.6%; *S. acrimycini*, AY999889, 99.4%; *S. griseoplanus*, AY999894, 99.4%; *S. fimicarius*, AY999784, 99.3%; *S. flavofuscus*, AB249935, 99.3%; *S. praecox*, AB184293, 99.3%; *S. mediolani*, AB184674, 99.3%; *S. anulatus*, DQ026637, 99.3%; *S. sindenensis*, AB184759, 99.2%; *S. griseinus*, AB184205, 99.2%; *S. rubiginosohelvolus*, AB184240, 99.2%; *S. badius*, AY999783, 99.2%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.2%; *S. cyaneofuscatus*, AB184860, 99.2%; *S. pluricolorescens*, DQ442540, 99.2%; *S. cinereorectus*, AB184646, 99.2%; *S. californicus*, AB184755, 99.2%; *S. lipmanii*, AB184148, 99.2%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.2%; *S. baarnensis*, EF178688, 99.1%; *S. floridae*, AB184656, 99.1%; *S. albovinaceus*, AB249958, 99.1%; *S. fulvorobeus*, AB184711, 99.1%; *S. microflavus*, DQ445795, 99.1%; *S. alboviridis*, AB184256, 99.1%; *S. globisporus* subsp. *globisporus*, EF178686, 99.1%; *S. griseus* subsp. *griseus*, AY207604, 99%; *S. argenteolus*, AB045872, 99%; *S. griseolus*, AB184768, 99%; *S. candidus*, DQ026663, 99%; *S. bacillaris*, AB184439, 99%; *S. luridiscabiei*, AF361784, 99%; *S. flavovirens*, DQ026635, 99%; *S. parvus*, DQ442537, 99%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1747, ATCC 43689, DSM 41691, INA 4305, NBRC 100999.

Sequence accession no. (16S rRNA gene): AB249951.

330. **Streptomyces naganishii** Yamaguchi and Saburi 1955, 219[AL]

na.ga.ni'shi.i. N.L. gen. masc. n. *naganishii* of Naganishi, named for Professor H. Naganishi of the University of Hiroshima, Japan.

Spore chains in Section *Spirales*. Mature spore chains are short to moderately long, usually with more than 10 spores per chain. This morphology is best developed on yeast-malt agar. Short spore chains on salts-starch agar and glycerol-asparagine agar may form incomplete spirals or hooks. Sporulation on oatmeal agar is especially poor. Aerial hyphae may terminate in atypical club-like swellings instead of spores. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or Red color series on yeast-malt agar and on carbon utilization medium plus D-glucose. The sporulated aerial growth on oatmeal agar, salts-starch agar, and glycerol-asparagine agar is usually white. Reverse side of colony is pale or grayish yellow to yellow-brown modified in spots or at margins by red (dark pink, purplish pink, or grayish reddish brown). Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth in 2 d, but are produced slowly or not at all in tyrosine agar. A transient red pigment is found in the medium in oatmeal agar and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of raffinose is doubtful. No growth or only traces of growth with sucrose.

Type strain shows the highest sequence similarity to: *Streptomyces geysiriensis*, DQ442501, 99; *Streptomyces minutiscleroticus*, EF178696, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23939, CBS 923.68, DSM 40282, NBRC 12892, JCM 4190, JCM 4654, NRRL B-1816, NRRL-ISP 5282, RIA 1196.

Sequence accession no. (16S rRNA gene): DQ442529.

331. **Streptomyces narbonensis** Corbaz, Ettlinger, Gäumann, Keller-Schierlein, Kradolfer, Kyburz, Neipp, Prelog, Reusser and Zähner 1955, 935[AL] ["*Streptomyces narboensis*" (*sic*) Corbaz, Ettlinger, Gäumann, Keller-Schierlein, Kradolfer, Kyburz, Neipp, Prelog, Reusser and Zähner 1955, 941]

nar.bo.nen′sis. L. masc. adj. *narbonensis* of or belonging to Narbonne, France, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Fragmentation of the substrate mycelium was noted by one observer only; unusual fragmentation of the aerial mycelium was recorded by another observer.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow to grayed greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only traces of growth on iso-inositol and D-mannitol.

Type strain shows the highest sequence similarity to: *S. zaomyceticus*, EF178685, 99.3%; *S. exfoliatus*, AB184324, 99.3%; *S. venezuelae*, AB045890, 99.3%; *S. lateritius*, AB184324, 99.2%; *S. wedmorensis*, DQ442557, 99.2%; *S. litmocidini*, AB184149, 99.1%; *S. omiyaensis*, EF178697, 99.1%.

Source: isolated from soil from Narbonne, a small community near Cannes on the Côte d'Azur, France.

DNA G+C content (mol%): not known.

Type strain: ATCC 19790, CBS 310.55, CBS 542.68, BCRC 13651, DSM 40016, NBRC 12801, JCM 4147, JCM 4596, NRRL B-1680, NRRL-ISP 5016, RIA 1069, RIA 529, UNIQEM 176, VKM Ac-1891.

Sequence accession no. (16S rRNA gene): DQ445794.

332. **Streptomyces nashvillensis** McVeigh and Reyes 1961, 312[AL]

nash.vil.len′sis. N.L. masc. adj. *nashvillensis* of or belonging to Nashville, a city in Tennessee, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Long chains, often with more than 50 spores, are predominantly straight but a very small number of these chains may show *Retinaculiaperti* morphology including some spirals. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray to 5fe, light grayish reddish brown or 5ih, brownish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is strong brown to light grayish brown on yeast-malt agar; grayish yellow, light olive gray, or yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is somewhat pH-sensitive changing from yellowish brown to reddish brown with addition of 0.05 M NaOH or from yellowish brown to yellow with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth, but melanin reaction may be delayed or weak in tyrosine agar. Yellow (to brown) pigment is found in the medium in yeast-malt agar and oatmeal agar and usually salts-starch agar and glycerol-asparagine agar. This pigment is somewhat pH-sensitive when tested with 0.05 M NaOH or HCl, showing the same color change noted for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, and raffinose are utilized for growth. Utilization of D-fructose is doubtful and there is no growth or only traces of growth with iso-inositol, D-mannitol, rhamnose, or sucrose.

Type strain shows the highest sequence similarity to: *S. tanashiensis*, AJ781362, 100%; *S. violaceorectus*, AB184314, 99.2%; *S. showdoensis*, AB184389, 99.1%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99.1%; *S. roseoviridis*, AB184239, 99.1%; *S. racemochromogenes*, DQ026656, 99.1%; *S. viridobrunneus*, AJ781372, 99.1%; *S. roseolus*, AB184168, 99%; *S. polychromogenes*, AB184292, 99%; *S. bikiniensis*, X79851, 99%.

Source: isolated from soil from Nashville, a city in Tennessee.

DNA G+C content (mol%): not known.

Type strain: ATCC 25476, CBS 886.69, BCRC 13625, DSM 40314, NBRC 13064, JCM 4498, NRRL B-2606, NRRL-ISP 5314, RIA 1256, VKM Ac-1766.

Sequence accession no. (16S rRNA gene): AB184286.

333. **Streptomyces netropsis** (Finlay et al. 1951) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) [*Streptoverticillium netropsis* (Finlay et al. 1951) Baldacci, Farina and Locci 1966, 161]

ne.trop′sis. Gr. n. *netron* spindle; Gr. fem. n. *opsis* aspect, appearance; N.L. masc. adj. *netropsis* spindle-like.

Spore chains in Umbellate monoverticillate (=*Streptomyces* Section Verticillati, biverticillate). Whorls may be composed of straight (BIV), flexuous, or spiral (BIV-S) spore chains. Mature spore chains generally have 10–20 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow to olive brown or brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in

peptone-yeast-iron agar, but not in tyrosine agar. No pigment or only a trace of yellow or brown pigment is found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar. Pigment, if present, may be slightly pH-sensitive changing from pale yellow to pale pink when tested with 0.05 M NaOH.

D-Glucose, iso-inositol, and D-fructose are utilized for growth. No growth or only trace of growth with L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. werraensis*, DQ442558, 99.3%; *S. biverticillatus*, AJ781381, 99.3%; *S. stramineus*, AB184720, 99.2%; *S. eurocidicus*, AY999790, 99.1%; *S. albireticuli*, AB184881, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23940, CBS 924.68, BCRC 13374, CECT 3265, DSM 40259, HUT 6086, IFM 1035, NBRC 12893, NBRC 3723, JCM 4063, JCM 4655, LMG 5979, NCIMB 9592, NRRL 2268, NRRL-ISP 5259, PCM 2251, RIA 1184, RIA 605, VKM Ac-820.

Sequence accession no. (16S rRNA gene): AB184848.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces netropsis* is proposed as a *nomen revictum* (basonym: "*Streptomyces netropsis*" Finlay et al. (1951).

According to Labeda (1996), *Streptomyces netropsis* (Finlay et al. 1951) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces distallicus* (Locci et al. 1969) Witt and Stackebrandt 1991, an earlier synonym of *Streptomyces flavopersicus* (Oliver et al. 1961) Witt and Stackebrandt 1991, and an earlier synonym of *Streptomyces kentuckensis* (Barr and Carman 1956) Witt and Stackebrandt 1991.

According to Hatano et al. (2003), *Streptomyces netropsis* (Finlay et al. 1951) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces distallicus* (Locci et al. 1969) Witt and Stackebrandt 1991, of *Streptomyces flavopersicus* (Oliver et al. 1961) Witt and Stackebrandt 1991, of *Streptomyces kentuckensis* (Barr and Carman 1956) Witt and Stackebrandt 1991, and of *Streptomyces syringium* (Konev 1986) Witt and Stackebrandt 1991.

334. **Streptomyces neyagawaensis** Yamamoto, Nakazawa, Horii and Miyake 1960, 286[AL]

ne.ya.ga.wa.en′sis. N.L. masc. adj. *neyagawaensis* of or belonging to Neyagawa City, Japan, near which the soil was obtained from which the organism was isolated.

Spore chains in Section *Spirales* on oatmeal agar and salts-starch agar. Short spore chains may form incomplete spirals (hooks) or flexuous to straight chains on yeast-malt agar and glycerol-asparagine agar. Spore chains are short on some media but long chains of 10–50 or more spores per chain may also be found. Spore chain morphology is often difficult to observe when spore chains and aerial hyphae coalesce in black moist (hygroscopic) masses. Spore surface is smooth. Surface of growth may become moist and black (hygroscopic) on older cultures.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray and 5fe, light grayish reddish brown on yeast-malt agar, oatmeal agar, and salts-starch agar; 2dc, yellowish gray or 5ih, brownish gray on glycerol-asparagine agar). Reverse side of colony is dark olive on yeast-malt agar; yellowish gray to light olive gray or brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment, or a trace of gray or olive brown pigment, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. hygroscopicus* subsp. *ossamyceticus*, AB184560, 99.4%; *S. torulosus*, AJ781367, 99.3%.

Source: isolated from soil near Neyagawa City, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 27449, CBS 778.72, DSM 40588, NBRC 13477, NBRC 3784, NRRL B-3092, NRRL-ISP 5588, RIA 1438, VKM Ac-1915, JCM 4796.

Sequence accession no. (16S rRNA gene): D63869.

335. **Streptomyces niger** (Thirumalachar 1955) Goodfellow, Williams and Alderson 1986a, 575[VP] (Effective publication: Goodfellow, Williams and Alderson 1986d, 59.) (*Chainia nigra* Thirumalachar 1955, 935)

ni′ger. L. masc. adj. *niger* black.

Forms extensively branched substrate and aerial mycelium. Spiral spore chains of smooth-surfaced spores are borne on the aerial mycelium. Aerial spore mass is white and the substrate mycelium is green. A green soluble pigment is produced. Sclerotia are formed in 7–14 d on agar media. Melanin pigments are not produced. Adenine, esculin, allantoin, arbutin, casein, elastin, guanine, hypoxanthine, pectin, starch, testosterone, L-tyrosine, xanthine, and xylan are degraded but chitin, lecithin, and urea are not. Nitrate is reduced but hydrogen sulfide is not produced. Adonitol, L-arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, inulin, D-lactose, D-mannitol, D-mannose, melibiose, melezitose, raffinose, L-rhamnose, salicin, sucrose, trehalose, xylitol, and D-xylose are all used as sole carbon sources. Acid is formed from adonitol, *meso*-erythritol, *myo*-inositol, D-lactose, D-mannitol, melibiose, methyl α-D-glucoside, raffinose, L-rhamnose, sucrose, and D-xylose but not from dulcitol or D-sorbitol. Grows on DL-α-amino-n-butyric acid, L-arginine, L-histidine, L-phenylalanine, potassium nitrate, L-serine, L-threonine, and L-valine, but not on L-cysteine or L-methionine as sole nitrogen source. Grows at 10, 37, and 45°C but not at 4°C. Tolerant to phenol (0.1%, w/v) and sodium azide (0.02%, w/v) and sodium chloride (10%, w/v). Resistant to rifampin but not to sodium chloride (13%, w/v). Antibiotic activity shown against *Bacillus subtilis* NCIB 3610 and *Saccharomyces cerevisiae* CBS 1171[T], but not against *Aspergillus niger* LIV 131, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046[T], or *Streptomyces murinus* ISP 5091. The organism has a type II phospholipid pattern (*sensu* Lechevalier et al., 1977) and contains major amounts of

hexahydrogenated menaquinones with nine isoprene units (Collins et al., 1984).

Type strain shows the highest sequence similarity to: *S. olivaceiscleroticus*, AJ621606, 100%; *S. monomycini*, DQ445790, 99.4%; *S. rimosus* subsp. *rimosus*, AB045883, 99.3%; *S. sclerotialus*, AJ621608, 99.2%; *S. purpurogeneiscleroticus*, AJ621604, 99.1%; *S. ochraceiscleroticus*, AB184094, 99.1%.

DNA G+C content (mol%): not known.

Type strain: ATCC 17756, CBS 230.65, CBS 663.72, BCRC 11877, CMI 112787, DSM 43049, KCC A-0158, NBRC 13362, NBRC 13902, JCM 3158, NCIMB 10992, NRRL B-3857, NRRL-ISP 5302, PCM 2305, RIA 1323, VKM Ac-1736.

Sequence accession no. (16S rRNA gene): AJ621607.

336. **Streptomyces nigrescens** (Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 70[AL] ("*Actinomyces nigrescens*" Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 146)

ni.gres'cens. L. part. adj. *nigrescens* becoming black.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth to warty.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. In the original description (Gauze et al., 1957), emphasis is placed on an autolytic change of gray aerial mycelium to a black shiny mass in ageing cultures. This phenomenon was not observed by ISP cooperators. Reverse side of colony with no distinctive pigments (colorless to grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only trace of growth with L-arabinose and rhamnose.

Type strain shows the highest sequence similarity to: *S. libani* subsp. *libani*, AB184414, 100%; *S. tubercidicus*, AJ621612, 99.9%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.6%; *S. libani* subsp. *rufus*, AJ781351, 99.6%; *S. caniferus*, AB184640, 99.5%; *S. catenulae*, AJ621613, 99.5%; *S. misakiensis*, AB217605, 99.5%; *S. sioyaensis*, DQ026654, 99.5%; *S. platensis*, AB045882, 99.5%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.2%; *S. lydicus*, Y15507, 99%; *S. chattanoogensis*, AJ621611, 99%.

Sequence accession no. (16S rRNA gene): DQ442530.

337. **Streptomyces nigrifaciens** Waksman 1961, 247[AL]

ni.gri.fa'ci.ens. L. adj. *niger -gra -grum* black; L. part adj. *faciens* producing; N.L. part adj. *nigrifaciens* producing black pigment.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown on yeast-malt agar, salts-starch agar, glycerol-asparagine agar, and grayed greenish yellow on oatmeal agar). Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. Some orange to yellow pigment found in medium in yeast-malt agar. In oatmeal agar, salts-starch agar, and glycerol-asparagine agar, yellow pigment is very faint or absent; it is not pH-sensitive.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, and raffinose. Variable reports on growth with D-fructose.

For sequence similarity, see type strain of *Streptomyces flavovirens*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19791, CBS 543.68, BCRC 13672, DSM 40071, NBRC 12802, JCM 4223, JCM 4597, LMG 20048, NCIMB 13019, NRRL B-2094, NRRL-ISP 5071, RIA 1070, UNIQEM 177, VKM Ac-1888.

Sequence accession no. (16S rRNA gene): AB184158.

Further comments: according to Lanoot et al. (2005b), *Streptomyces nigrifaciens* Waksman 1961 is a later heterotypic synonym of *Streptomyces flavovirens* (Waksman 1923) Waksman and Henrici 1948 emend. Lanoot et al. 2005b.

338. **Streptomyces nitrosporeus** Okami 1952, 477[AL]

ni.tro.spo're.us. N.L. n. *nitras* nitrate; Gr. n. *spora* a seed; N.L. n. *spora* a spore; N.L. masc. adj. *nitrosporeus* nitrate spored, name is based on rapid spore formation accompanied by vigorous reduction of nitrate.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. Indistinct yellow, gray, or brownish gray pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; it is not pH-sensitive.

D-Glucose, L-arabinose, D-xylose, and rhamnose utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, D-mannitol, and raffinose. Variable reports with D-fructose.

Type strain shows the highest sequence similarity to: *S. flavogriseus*, AJ494864, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. mediolani*, AB184674, 99.5%; *S. rubiginosohelvolus*, AB184240, 99.5%; *S. badius*, AY999783, 99.5%; *S. cinereorectus*, AB184646, 99.5%; *S. albovinaceus*, AB249958, 99.5%; *S. praecox*, AB184293, 99.5%; *S. flavofuscus*, AB249935, 99.5%; *S. globisporus* subsp. *globisporus*, EF178686, 99.5%; *S. pluricolorescens*, DQ442540, 99.5%; *S. sindenensis*, AB184759, 99.5%; *S. griseinus*, AB184205, 99.5%; *S. fimicarius*, AY999784, 99.5%; *S. anulatus*, DQ026637, 99.5%; *S. griseolus*, AB184768, 99.5%; *S. californicus*, AB184755, 99.4%; *S. parvus*, DQ442537, 99.4%; *S. bacillaris*, AB184439, 99.4%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.4%; *S. argenteolus*, AB045872, 99.4%; *S. griseoplanus*, AY999894, 99.4%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.4%; *S. acrimycini*, AY999889, 99.4%; *S. halstedii*, EF178695, 99.4%; *S. alboviridis*, AB184256, 99.3%; *S. baarnensis*, EF178688, 99.3%; *S. pulveraceus*, AB184806, 99.3%; *S. fulvorobeus*, AB184711, 99.3%; *S. lipmanii*, AB184148, 99.3%; *S. microflavus*, DQ445795, 99.3%; *S. cyaneofuscatus*, AB184860, 99.3%; *S. floridae*, AB184656, 99.3%; *S. griseus* subsp. *griseus*, AY207604, 99.2%; *S. luridiscabiei*, AF361784, 99.2%; *S. albolongus*, AB184425, 99.1%; *S. celluloflavus*, AB184476, 99.1%; *S. sanglieri*, AB249945, 99.1%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.1%; *S. olivoviridis*, AB184227, 99%; *S. griseobrunneus*, AB249912, 99%; *S. atratus*, DQ026638, 99%; *S. finlayi*, AY999788, 99%; *S. atroolivaceus*, AJ781320, 99%; *S. yanii*, AB006159, 99%; *S. gelaticus*, DQ026636, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 12769, ATCC 19792, CBS 544.68, BCRC 13645, DSM 40023, HUT 6032, NBRC 12803, NBRC 3362, JCM 4064, JCM 4598, KCTC 9761, NCIMB 9717, NRRL B-1316, NRRL-ISP 5023, RIA 1071, RIA 503, UNIQEM 178, VKM Ac-1191, VKM Ac-1202.

Sequence accession no. (16S rRNA gene): EF178680.

339. **Streptomyces niveiscabiei** Park, Kim, Kwon, Wilson, Yu, Hur and Lim 2003, 2053[VP]

ni.ve.i.sca'bi.ei. L. adj. *niveus* snow-white; L. n. *scabies* roughness, scabbiness; N.L. gen. n. *niveiscabiei* of white scab, intended to mean white and scab-causing bacteria.

Spores are white, smooth, and borne in simple rectus flexuous spore chains. Melanin is not produced on tyrosine or peptone agars. L-Arabinose, D-fructose, D-glucose, D-mannitol, raffinose, rhamnose, sucrose, D-xylose, and iso-inositol are utilized for growth. Minimum pH for growth is 3.5. Sensitive to 5, 6, and 7% (w/v) NaCl, 20 and 100 μg/ml thallium acetate, 0.5 μg/ml crystal violet, 0.1% (w/v) phenol, 25 and 100 μg/ml oleandomycin, and 20 μg/ml streptomycin, but not to 10 IU/ml penicillin.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. scabies* ATCC 49173^T, 16%; *S. turgidiscabies* ATCC 700248^T, 15%; *S. acidiscabies* ATCC 49003^T, 17%; *S. bottropensis* DSM 40262^T, 15%; *S. neyagawaensis* DSM 40588^T, 18%; *S. diastatochromogenes* DSM 40449^T, 19%; *S. setonii* DSM 40395^T, 15%; *S. griseus* subsp. *griseus* DSM 40236^T, 22%; *S. sampsonii* DSM 40394^T, 19%; *S. eurythermus* DSM 40014^T, 17%; *S. tendae* DSM 40101^T, 16%; *S. coelicolor* DSM 40233^T, 12%; " *S. lividans*" DSM 40434, 19%; *S. ambofaciens* DSM 40053^T, 15%; *S. luridiscabiei* LMG 21390^T, 17%; *S. puniciscabiei* LMG 21391^T, 13%.

Source: isolated from raised corky lesions on potato cv. Daeji-ma and pathogenic on potato cv. Daeji-ma.

DNA G+C content (mol%): 70.1.

Type strain: S78, KACC 20254, LMG 21392.

Sequence accession no. (16S rRNA gene): AF361786.

340. **Streptomyces niveoruber** Ettlinger, Corbaz and Hütter 1958a, 350[AL]

ni.ve.o.ru'ber. L. adj. *niveus* snow-white; L. adj. *ruber* red; N.L. masc. adj. *niveoruber* snow-white-red (referring to the white color of the aerial mycelium and red color of the vegetative mycelium).

Excellent growth on Czapek's solution agar; forms red vegetative mycelium on some media. This taxon might also be placed in the White color series. Produces cinerubins A and B.

Type strain shows the highest sequence similarity to: *S. lucensis*, DQ442522, 99.5%; *S. achromogenes* subsp. *achromogenes*, AB184109, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 14971, DSM 40638, NBRC 15428, IMET 43354, JCM 4234, NRRL B-2724.

Sequence accession no. (16S rRNA gene): DQ445796.

341. **Streptomyces niveus** Smith, Dietz, Sokolski and Savage 1956, 135[AL]

ni've.us. L. masc. adj. *niveus* snow-white, referring to the color of the aerial mycelium of the organism.

Spore chains in Section *Spirales*, with as many as 10 or more well-formed volutions of narrow diameter at the ends of long sporophores. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. Pigment, other than traces of yellow, are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, and D-fructose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, and raffinose. Variable reports on growth with L-arabinose, D-mannitol, and rhamnose. However, reports from four cooperating laboratories indicate unusual disagreement regarding carbon utilization by this strain. The original description includes sucrose, rhamnose, and raffinose among carbon sources utilized for growth.

For sequence similarity, see type strain of *Streptomyces caeruleus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19793, CBS 545.68, BCRC 11514, CCUG 11108, DSM 40088, IFM 1181, NBRC 12804, IMET 43503, JCM 4251, JCM 4599, LMG 5980, LMG 19395, NCIMB 9219, NRRL 2466, NRRL-ISP 5088, RIA 1072, UNIQEM 179.

Sequence accession no. (16S rRNA gene): AB184160.

Further comments: according to Lanoot et al. (2002), *Streptomyces niveus* (Smith et al. 1956) is a later heterotypic synonym of *Streptomyces caeruleus* (Baldacci 1944) Pridham et al. 1958 emend. Lanoot et al. 2002.

342. **Streptomyces noboritoensis** Isono, Yamashita, Tomiyama, Suzuki and Sakai 1957, 21[AL]

no.bo.ri.to.en′sis. N.L. masc. adj. *noboritoensis* of or belonging to noborito, referring to Inada-noborito, Kawasaki City, Kanagawa Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although the aerial mycelium may be thin or poorly developed on some of these media. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar when mature sporulating mycelium is produced in adequate amount. Development of aerial mycelium may not be adequate for spore mass color determination on some or these media. Reverse side of colony is yellow to yellow brown modified to dark reddish brown or very dark brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but may be absent or present only in trace amount in tyrosine agar. Brown pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar or pigment may be absent from these media. The brown pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and raffinose are utilized for growth. Reports vary on the utilization of iso-inositol and utilization of sucrose is doubtful. No growth or only trace of growth with rhamnose.

Type strain shows the highest sequence similarity to: *S. melanogenes*, AB184222, 100%; *S. crystallinus*, AB184652, 99.2%.

Source: isolated from soil from Inada-noborito, Kawasaki City, Kanagawa Prefecture, Japan.

DNA G+C content (mol%): not known.

Type strain: AS 4.1457, ATCC 25477, CBS 887.69, BCRC 11553, DSM 40223, NBRC 13065, JCM 4065, JCM 4557, KCTC 9060, LMG 19337, NRRL B-12152, NRRL-ISP 5223, RIA 1257, VKM Ac-1012.

Sequence accession no. (16S rRNA gene): AB184287.

343. **Streptomyces nodosus** Trejo *in* Waksman 1961, 250[AL]

no.do′sus. L. masc. adj. *nodosus* knotty.

Spore chains in Section *Spirales*. Spirals on short spore chains may be poorly developed showing only a few turns or hooks of small diameter; or tightly knotted spirals may be formed. Spore chains are short, often with only 3–10 spores per chain. This morphology is seen on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth, but some wrinkles or folds are found on the spore surface.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow or grayed greenish yellow to dark olive brown or near black on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast extract broth. Traces of red or yellow orange pigment may be found in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. One observer reports this pigment is pH-sensitive changing from red to green by addition of 0.05 M NaOH and from green to blue-red by 0.05 M HCl.

D-Glucose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose. Utilization of L-arabinose is doubtful.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1459, ATCC 14899, ATCC 23942, CBS 926.68, BCRC 13768, DSM 40109, NBRC 12895, JCM 4297, JCM 4656, KCTC 9035, LMG 19340, NCIMB 12816, NRRL B-2371, NRRL-ISP 5109, RIA 1123, RIA 831, VKM Ac-1224.

Sequence accession no. (16S rRNA gene): AF114033.

344. **Streptomyces nogalater** Bhuyan and Dietz 1966, 838[AL]

no.gal.at′er. Spanish n. *nogal* walnut; L. adj. *ater* black; N.L. masc. adj. *nogalater* black walnut, referring to the production (by the organism) on most media of an odor like that of black walnuts.

Spore chains in Section *Rectiflexibiles* to *Retinaculiaperti* or possibly *Spirales*. Spore chains may be straight, strongly flexuous, or in irregular spirals. Straight to flexuous chains are usually seen on yeast-malt agar and glycerol-asparagine agar; strongly flexuous, *Retinaculiaperti* or *Spirales* spore chains may be found on oatmeal agar and salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (3fe or 4ig, light brownish gray; 4li, brownish gray; 3ig, grayish yellowish brown; or 2ih, light olive gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is orange-yellow to light yellowish pink on yeast-malt agar; light yellow to orange yellow on oatmeal agar; pale or grayish yellow on salts-starch agar and glycerol-asparagine agar. One observer

reports that the reverse mycelium pigment is a pH indicator changing from orange to dark red or dark violet with the addition of 0.05 M NaOH and from orange to yellow orange with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red or yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. One observer reports that this pigment is pH-sensitive, showing the same changes observed with the reverse mycelium pigments when 0.05 M NaOH or HCl is added.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, and raffinose are probably utilized for growth, but reports vary for L-arabinose, D-fructose, and rhamnose. No growth or only traces of growth is seen with sucrose or iso-inositol.

Type strain shows the highest sequence similarity to: *Streptomyces eurythermus*, D63870, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1442, ATCC 27451, CBS 238.69, CBS 746.72, BCRC 12316, DSM 40546, HAMBI 951, NBRC 13445, IMET 43360, JCM 4553, JCM 4799, LMG 5981, LMG 19338, NCIMB 9489, NRRL 3035, NRRL-ISP 5546, RIA 1406, VKM Ac-1290.

Sequence accession no. (16S rRNA gene): AB045886.

345. **Streptomyces nojiriensis** Ishida, Kumagai, Niida, Hamamoto and Shomura 1967, 64[AL]

no.ji.ri.en′sis. N.L. masc. adj. *nojiriensis* of or belonging to Nojiri, named for Lake Nojiri at Nagano, Japan, the source of the soil from which the organism was isolated.

Poor growth on Czapek's solution agar. Produces nojirimycin, an anti-bacterial antibiotic.

Type strain shows the highest sequence similarity to: *S. xanthophaeus*, DQ442560, 100%; *S. spororaveus*, AJ781370, 100%; *S. goshikiensis*, EF178693, 99.9%; *S. cirratus*, AY999794, 99.9%; *S. vinaceus*, AB184394, 99.9%; *S. colombiensis*, DQ026646, 99.8%; *S. sporoverrucosus*, DQ442544, 99.8%; *S. cinnamonensis*, AB184707, 99.7%; *S. avidinii*, AB184395, 99.7%; *S. subrutilus*, X80825, 99.7%; *S. virginiae*, D85119, 99.5%; *S. racemochromogenes*, DQ026656, 99%; *S. polychromogenes*, AB184292, 99%.

Source: isolated from soil from Lake Nojiri at Nagano, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 29781, DSM 41655, NBRC 13794, JCM 3382, KCTC 9784, NRRL B-16930.

Sequence accession no. (16S rRNA gene): AJ781355.

346. **Streptomyces noursei** Brown, Hazen and Mason 1953, 609[AL]

nour′sei. N.L. gen. masc. n. *noursei* of Nourse, referring to the owner of the farm where soil was obtained from which the organism was isolated.

Poor growth on Czapek's solution agar; NaCl tolerance >7%, but <10%. Exhibits anti-bacterial activity; produces nystatin and cycloheximide.

Type strain shows the highest sequence similarity to: *S. albulus*, AB024440, 100%; *S. yunnanensis*, AF346818, 99.7%.

Source: isolated from soil.

DNA G+C content (mol%): not known.

Type strain: ATCC 11455, CBS 240.57, BCRC 12044, CECT 3240, DSM 40635, NBRC 15452, JCM 4922, KCTC 1083, LMG 5982, NCIMB 8593, NRRL B-1714.

Sequence accession no. (16S rRNA gene): AB184678.

347. **Streptomyces novaecaesareae** Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 951[AL]

no.va.e.ca.e.sa.re′a.e. N.L. gen. n. *novaecaesareae* intended to mean of New Jersey, USA.

Spore chain section undetermined. Aerial mycelium is not found on any of the ISP media. The original description for *Actinomyces violaceus-caeseri* Waksman and Curtis (1916) states that on Czapek agar: "Aerial mycelium produced very late; … Conidia could not be demonstrated", and little or no aerial mycelium was reported for other media included in the original description. Spore surface undetermined. Color of colony: not determined. Reverse side of colony with distinctive grayish blue or blue green to grayish violet or red violet pigment is produced on oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but the pigment is not always present on these media. Reverse mycelium is usually grayish yellow to grayish olive on yeast-malt agar. Reverse mycelium pigment is a pH indicator changing from pale violet to pale grayish blue with the addition of 0.05 M NaOH and from pale violet to reddish violet or pale grayish red with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Blue or violet pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; it is most consistently present in oatmeal agar. This pigment is pH-sensitive showing the same changes reported for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. aureocirculatus*, AB184260, 99.5%; *S. pseudovenezuelae*, AB184233, 99.5%; *S. phaeoluteigriseus*, AJ391815, 99.5%; *S. galilaeus*, AB045878, 99.4%; *S. resistomycificus*, AB184166, 99.3%; *S. bobili*, AB249925, 99.3%; *S. humidus*, DQ442508, 99.1%; *S. chartreusis*, AB184839, 99.1%; *S. flavovariabilis*, EF178691, 99.1%; *S. canus*, AY999775, 99%; *S. prunicolor*, DQ026659, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1471, ATCC 27452, CBS 134.20, CBS 669.72, DSM 40358, NBRC 13368, JCM 4800, NRRL B-1267, NRRL B-3011, NRRL-ISP 5358, RIA 1329, VKM Ac-963.

Sequence accession no. (16S rRNA gene): AB184357.

348. **Streptomyces ochraceiscleroticus** Pridham 1970, 22[AL]

o.chra.ce.i.scle.ro′ti.cus. L. n. *ochra* ochre; N.L. adj. *ochraceus* like-ochre, rust colored; N.L. n. *sclerotium* sclerotium; N.L. masc. adj. *ochraceiscleroticus* sclerotium with rust color.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10 to 50 or more spores per chain.

This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Sclerotia-like granules are formed on glycerol-asparagine agar and other media.

Color of colony: aerial mass color in the Yellow or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. White or gray aerial mycelium may also be seen on these media. Nearest matching color tab recorded for the Yellow color series is 2ba, pale yellow; nearest tabs in the Red color series are 4ie, light brown, and 3ea, light orange-yellow. Reverse side of colony is strong brown, moderate orange, or orange-yellow on yeast-malt agar and glycerol-asparagine agar; light yellow, yellow or light yellowish brown on oatmeal agar and salts-starch agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. purpurogeneiscleroticus*, AJ621604, 99.9%; S. *violens*, AJ621605, 99.8%; *S. monomycini*, DQ445790, 99.5%; *S. erumpens*, AJ621603, 99.3%; *S. sioyaensis*, DQ026654, 99.1%; *S. olivaceiscleroticus*, AJ621606, 99.1%; *S. niger*, AJ621607, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1096, ATCC 15814, CBS 168.62, CBS 784.72, BCRC 13310, DSM 40594, DSM 43155, NBRC 12394, NBRC 13483, IMET 43492, JCM 3048, JCM 4801, LMG 19349, NRRL B-3041, NRRL-ISP 5594, PCM 2307, RIA 1444, RIA 710, VKM Ac-651.

Sequence accession no. (16S rRNA gene): AB184094.

Further comments: Streptomyces ochraceiscleroticus Pridham 1970 and *Chainia ochracea* Kuznetsov 1962 have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b (1) of the *Bacteriological Code* (1990 Revision)].

349. **Streptomyces odorifer** (Rullman 1895) Waksman *in* Waksman and Lechevalier 1953, 79[AL] ["*Cladothrix odorifera*" Rullmann 1895, 44; "*Oospora odorifera*" Lehmann and Neumann 1896, 392; "*Actinomyces odoriferus rullmanni I*" (*sic*) Berestnev 1897, 167; "*Cladothrix odoriferus rullmanni I*" (*sic*) Berestnev 1897, 167; "*Actinomyces odorifer*" Lachner-Sandoval 1898, 65; "*Streptothrix odorifera*" Foulerton and Price-Jones 1902, 112; "*Nocardia odorifera*" Castellani and Chalmers 1913, 818]

o.do'ri.fer. L. masc. adj. *odorifer* fragrant.

Spore chains in Section *Rectiflexibiles*. Flexuous chains are common. Mature spore chains generally contain 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but aerial mycelium may be poorly developed on salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (1ba, 2ba, or 2db, pale yellow, or 1dc, pale yellow green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (strong brown to olive brown on yeast-malt agar; light yellow to greenish yellow, grayish yellow, or light brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment is found in the medium in yeast-malt agar and salts-starch agar. One observer also reports yellow pigment on oatmeal agar and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and sucrose are utilized for growth. No growth or only traces of growth with iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. violascens*, AY999737, 100%; *S. hydrogenans*, AB184868, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. canescens*, AB184117, 100%; *S. sampsonii*, D63871, 99.9%; *S. koyangensis*, AY079156, 99.7%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 6246, CBS 666.72, BCRC 13704, CECT 3178, DSM 40347, NBRC 13365, IMET 41377, JCM 4198, JCM 4803, NRRL B-1328, NRRL-ISP 5347, RIA 1326, VKM Ac-748.

Sequence accession no. (16S rRNA gene): Z76682.

350. **Streptomyces olivaceiscleroticus** (Thirumalachar and Sukapure 1964) Pridham 1970, 41[AL] (*Chainia olivacea* Thirumalachar and Sukapure 1964, 160)

o.li.va.ce.i.scle.ro'ti.cus. N.L. adj. *olivaceus* olive colored; N.L. n. *sclerotium* sclerotium; N.L. masc. adj. *olivaceiscleroticus* sclerotium with olive color.

Spore chains in Section *Spirales*. Mature spore chains generally contain 10–50 spores per chain. This morphology may be seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, or sporulating aerial mycelium may be poorly developed on various media. Spore surface is smooth. Tight spirals may coalesce. One of three observers reports sclerotia formation.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray; 3ge light grayish yellowish brown; 3–4li, brownish gray; or 2ge, light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. White or yellow (2ba, pale yellow) aerial mycelium is also reported. Reverse side of colony with no distinctive pigments (grayish yellow to olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast

broth. Reddish pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar. Yellowish green pigment may be present in yeast-malt agar and glycerol-asparagine agar, or pigment may be absent in these media; pigments are not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. niger*, AJ621607, 100%; *S. monomycini*, DQ445790, 99.4%; *S. rimosus* subsp. *rimosus*, AB045883, 99.3%; *S. sclerotialus*, AJ621608, 99.2%; *S. purpurogeneiscleroticus*, AJ621604, 99.1%; *S. ochraceiscleroticus*, AB184094, 99.1%.

DNA G+C content (mol%): not known.

Type strain: ATCC 15722, CBS 296.66, CBS 785.72, BCRC 11608, DSM 40595, NBRC 13484, JCM 3045, JCM 4805, NRRL B-2318, NRRL-ISP 5595, RIA 1445.

Sequence accession no. (16S rRNA gene): AJ621606.

Further comments: Streptomyces olivaceiscleroticus Pridham 1970 and *Chainia olivacea* Thirumalachar and Sukapure 1964 have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b (1) of the *Bacteriological Code* (1990 Revision)].

351. **Streptomyces olivaceoviridis** (Preobrazhenskaya and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 65[AL] ("*Actinomyces olivaceoviridis*" Preobrazhenskaya and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 163)

o.li.va.ce.o.vi′ri.dis. N.L. adj. *olivaceus* olive colored; L. adj. *viridis* green; N.L. masc. adj. *olivaceoviridis* olive-green colored, referring to the gray-olive colored aerial mycelium and greenish gray-brown vegetative mycelium on a chemically defined medium.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Hooks, loops, and terminal spirals of only one or two turns are common; flexuous chains and primitive spirals may also be found. Mature spore chains generally contain 10 to 50 or more spores per chain. This morphology is seen on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; spore chains may be short or poorly developed on yeast-malt agar. Spore surface is smooth.

Color of colony: aerial mass color usually in the Gray or Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The aerial mass color is usually pale yellowish green to grayish yellow or even light grayish olive (tabs 1cb or 1½ec from the Yellow color series; 2dc or 2ge from the Gray color series or 3ec from the Red color series; 1½ge from the Green color series). Immature aerial mycelium may also appear to be in the White color series. Reverse side of colony with no distinctive pigments (pale yellow to orange-yellow on yeast-malt agar; pale yellow to grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment, or only a trace of yellow, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth. Some growth is also reported on iso-inositol, but less than with the other carbon sources noted above.

Type strain shows the highest sequence similarity to: *S. canarius*, AB184396, 100%; *S. corchorusii*, AB184267, 99.9%; *S. capoamus*, AB045877, 99.5%; *S. bungoensis*, AB184696, 99.3%; *S. galbus*, X79852, 99.2%; *S. longwoodensis*, AB184580, 99.2%; *S. cellostaticus*, AB184192, 99%; *S. griseochromogenes*, AB184387, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1430, ATCC 23630, ATCC 25478, CBS 888.69, DSM 40334, NBRC 13066, IMET 43128, INA 11584, JCM 4499, KCTC 9132, LMG 19324, NCIMB 9982, NRRL B-12280, NRRL-ISP 5334, RIA 1258, VKM Ac-1852.

Sequence accession no. (16S rRNA gene): AB184288.

352. **Streptomyces olivaceus** (Waksman 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 950[AL] ("*Actinomyces olivaceus*" Waksman 1923, 354)

o.li.va′ce.us. N.L. masc. adj. *olivaceus* olive colored, apparently referring to the color of vegetative mycelium.

Spore chains in Section *Spirales*, with open spirals intergrading through flexuous spore chains suggestive of Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is usually grayed yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Production of dark reverse color is variable on these media; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. pactum*, AB184398, 100%; *S. parvulus*, AB184326, 99.3%; *S. coeruleorubidus*, AY999719, 99.2%; *S. rubrogriseus*, AB184681, 99.2%; *S. lienomycini*, AJ781353, 99.2%; *S. anthocyanicus*, AB184631, 99.1%; *S. tricolor*, AB184687, 99%; *S. malachitospinus*, AB249954, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19794, ATCC 3335, CBS 546.68, CCM 3188, BCRC 11485, CCUG 11111, DSM 40072, NBRC 12805, INA 3200, JCM 4402, NRRL B-1224, NRRL B-3009, NRRL-ISP 5072, RIA 1073, RIA 481, UNIQEM 180, VKM Ac-254.

Sequence accession no. (16S rRNA gene): AB184743.

353. **Streptomyces olivochromogenes** (Waksman 1923) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 941[AL] ["*Actinomyces olivochromogenus*" (*sic*) Waksman 1923; "*Streptomyces olivochromogenus*" (*sic*) Waksman and Henrici 1948]

o.li.vo.chro.mo′ge.nes. L. n. *oliva* olive; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. adj. *olivochromogenes* producing an olive color.

Spore chains in Section *Spirales*, but sporulation aerial mycelium is poorly developed and spore chains are generally short (3–10 spores per chain) so that flexuous chains, hooks, loops, and imperfect or irregular spirals are common. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, Czapek's sucrose agar, and soil agar. The abundant cottony aerial mycelium mentioned in the original description (op. cit) is not seen on ISP media. Spore surface is smooth.

Color of colony: sporulation on yeast-malt agar, oatmeal agar, salts-starch agar and glycerol-asparagine agar is inadequate for accurate spore mass color determination. Reverse side of colony with no distinctive pigments (nearly colorless or grayish yellow to grayish greenish yellow or moderate yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, and tryptone-yeast broth; a faint brown pigment may be also produced in tyrosine agar in 4 d. A trace of yellow or greenish pigment may or may not be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and sucrose are utilized for growth. No growth or only trace of growth with raffinose.

Type strain shows the highest sequence similarity to: *S. mirabilis*, AB184412, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25479, ATCC 3336, CBS 889.69, DSM 40451, NBRC 13067, NBRC 3178, IMET 40352, JCM 4163, JCM 4500, KCTC 9064, NRRL B-1341, NRRL-ISP 5451, RIA 1259.

Sequence accession no. (16S rRNA gene): AY094370.

354. **Streptomyces olivomycini** (Gause and Sveshnikova 1986b) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium olivomycini* Gause and Sveshnikova (Gause and Sveshnikova 1986b)

o.li.vo.my.ci′ni. N.L. n. *olivomycinum* olivomycin; N.L. gen. n. *olivomycini* of olivomycin, intended to mean olivomycin producing.

Spore chains are straight, spores are smooth. On mineral agar 1: aerial mycelium is creamy, pale lilac with a brownish note; substrate mycelium is brownish-greenish, brownish-olive, grayish-greenish; no diffusible pigment. On starch-ammonia agar (ISP 4): aerial mycelium is creamy, poor; substrate mycelium is brownish-gray, weak growth; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is creamy; substrate mycelium is brownish-greenish, olive green; diffusible pigment is greenish, weak. On glycerol-asparagine agar (ISP 5): aerial mycelium is pale lilac; substrate mycelium is brown-gray greenish; no diffusible pigment. On oatmeal agar: aerial mycelium is creamy, pale lilac; substrate mycelium is olive to brownish; diffusible pigment is light greenish. On organic agar 2: aerial mycelium yellowish to light pink; substrate mycelium is yellowish-brownish to greenish; no diffusible pigment.

Melanoid pigments are not formed. Carbon utilization: weak digestion of sucrose, arabinose, rhamnose, xylose, fructose, raffinose, and mannitol. Antibiotic: olivomycin.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: INA 16749.

Sequence accession no. (16S rRNA gene): no sequence available.

355. **Streptomyces olivoreticuli** (Arai, Nakada and Suzuki 1957) Witt and Stackebrandt 1996, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces olivoreticuli*" Arai, Nakada and Suzuki 1957, 441; *Streptoverticillium olivoreticuli* Baldacci, Farina and Locci 1966, 162)

o.li.vo.re.ti′cu.li. L. n. *oliva* olive; L. n. *reticulum* small net; N.L. gen. n. *olivoreticuli* of olive-colored net, itended to mean having the appearance of olive-colored nets.

Spore chains in Umbellate monoverticillate (=*Streptomyces* Section Verticillati, biverticillate). Mature spore chains are generally short with 3–10 spores per chain. This morphology may be observed on Pridham and Gottlieb carbon utilization medium with glucose or inositol, but good sporulation is usually not seen on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on media supporting sporulating aerial growth. In the absence of sporulation, the surface is pale yellow on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar and white on salts-starch agar. Reverse side of colony with no distinctive pigments (colorless to grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Carbon utilization appears to be unusually variable. Reports from three observers differ on utilization of each carbon source tested and results vary on duplicate dishes in the same laboratory. The original description (op. cit.) directs attention to fluctuation of carbon utilization by ultra-violet irridiated strains. This fluctuation appears also to be a characteristic of the type strain.

For sequence similarity, see type strain of *Streptomyces abikoensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23943, CBS 927.68, BCRC 13765, DSM 40105, IFM 1018, NBRC 12896, IMET 43690, JCM 4176, JCM 4657, NRRL B-2091, NRRL-ISP 5105, RIA 1122, VKM Ac-839.

Sequence accession no. (16S rRNA gene): AB184853.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces olivoreticuli* is proposed as a *nomen revictum* (basonym: "*Streptomyces olivoreticuli*" Arai et al. (1957).

Witt and Stackebrandt proposed to transfer *Streptoverticillium olivoreticuli* corrig. (Arai et al. 1957) Baldacci et al. (1966) to the genus *Streptomyces* as *Streptomyces olivoreticuli* (Arai et al. 1957) Witt and Stackebrandt 1991. However, Validation List no. 38 does not include formal propositions about *Streptoverticillium olivoreticuli* subsp. *cellulophilum* corrig. Locci and Schofield 1989 and *Streptoverticillium olivoreticuli* subsp. *olivoreticuli* corrig. (Arai et al. 1957) Baldacci et al. 1966.

According to Hatano et al. (2003), *Streptomyces olivoreticuli* (Arai et al. 1957) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces abikoensis* (Umezawa et al. 1951) Witt and Stackebrandt 1991.

356. **Streptomyces olivoverticillatus** (Shinobu 1956) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces olivoverticillatus*" Shinobu 1956, 92; "*Verticillomyces olivoverticillatus*" Shinobu 1965; *Streptoverticillium olivoverticillatum* Baldacci, Farina and Locci 1966, 163)

o.li.vo.ver.ti.cil.la′tus. L. n. *oliva* olive; L. n. *verticillus* a whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *olivoverticillatus* olive, whorled.

Spore chain Section not determined. The original description of Shinobu ((1956), op. cit) states: "The formation of aerial mycelium of this strain was generally not good, even on a suitable media for growth". ISP observers found some aerial mycelium with straight, flexuous, and abortive spiral spore chains on oatmeal agar. Electron microscope preparations from yeast-malt agar, oatmeal agar, and salts-starch agar contained some flexuous to spiral chains of 13 to 20 or more spores. "Whirls" as described by Shinobu ((1956), op. cit) were not found by ISP observers. Spore surface is spiny.

Color of colony: aerial mass color probably in the Yellow or Gray color series (1db, pale yellow green; 3fe light brownish gray) when mature spores occur on yeast-malt agar, oatmeal agar, and salts-starch agar. Thin or immature aerial mycelium is white. Reverse side of colony with no distinctive pigments (nearly colorless, yellow, greenish yellow or olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Brown or yellow-brown pigment may be found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar or the medium may remain unpigmented.

D-Glucose and iso-inositol are utilized for growth. Utilization of L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose is doubtful.

Type strain shows the highest sequence similarity to: *S. thioluteus*, AB184753, 99.1%; *S. abikoensis*, AB184537, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25480, CBS 890.69, BCRC 13610, CECT 3266, DSM 40250, NBRC 13068, NBRC 15273, NBRC 3842, NBRC 3929, JCM 4100, JCM 4501, NCIMB 97148, NRRL B-1994, NRRL-ISP 5250, RIA 1260, RIA 551, VKM Ac-890.

Sequence accession no. (16S rRNA gene): AB184636.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces olivoverticillatus* is proposed as a *nomen revictum* (basonym: "*Streptomyces olivoverticillatus*" Shinobu 1956).

According to Hatano et al. (2003), *Streptomyces olivoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 is an earlier heterotypic synonym of *Streptomyces viridiflavus* corrig. (Locci and Schofield 1989) Witt and Stackebrandt 1991.

357. **Streptomyces olivoviridis** (Kuchaeva, Krasil'nikov, Skryabin and Taptykova *in* Rautenshtein 1960) Pridham 1970, 23[AL] ["*Actinomyces olivoviridis*" Kuchaeva, Krasil'nikov, Skryabin and Taptykova *in* Rautenshtein 1960; "*Actinomyces olivovirilis*" (*sic*) Kuchaeva, Krasil'nikov, Skryabin and Taptykova *in* Rautenshtein 1960]

o.li.vo.vi′ri.dis. L. n. *oliva* olive; L. adj. *viridis* green; N.L. masc. adj. *olivoviridis* olive-green.

Spore chains in Section *Rectiflexibiles.* The predominantly flexuous or wavy spore chains may also form occasional hooks and open spirals (rare) resembling *Retinaculiaperti* or Spiral morphology. Mature spore chains are generally long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar; aerial mycelium is poorly developed or white on glycerol-asparagine agar. Reverse side of colony is yellow to yellow brown is usually modified by green (olive brown to yellow green or grayish green) on yeast-malt agar, oatmeal agar, and salts-starch agar; no distinctive substrate mycelium pigment on glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar or tyrosine agar. Some coloration may appear in medium in tryptone-yeast broth. Yellow or green pigment is found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth with sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. clavifer*, DQ026670, 100%; *S. atroolivaceus*, AJ781320, 100%; *S. mutomycini*, AB249951, 99.7%; *S. finlayi*, AY999788, 99.7%; *S. sindenensis*, AB184759, 99.5%; *S. fimicarius*, AY999784, 99.5%; *S. pluricolorescens*, DQ442540, 99.5%; *S. griseoplanus*, AY999894, 99.5%; *S. griseinus*, AB184205, 99.5%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.5%; *S. mediolani*, AB184674, 99.5%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.5%; *S. flavofuscus*, AB249935, 99.5%; *S. badius*, AY999783, 99.5%; *S. anulatus*, DQ026637, 99.5%; *S. rubiginosohelvolus*, AB184240, 99.5%; *S. praecox*, AB184293, 99.5%; *S. albovinaceus*, AB249958, 99.4%; *S. cinereorectus*, AB184646, 99.4%; *S. lipmanii*, AB184148, 99.4%; *S. baarnensis*, EF178688, 99.4%; *S. fulvorobeus*,

358. **Streptomyces omiyaensis** Umezawa and Okami *in* Umezawa,Tazaki, Okami and Fukuyama 1950, 293[AL]

o.mi.ya.en′sis. N.L. masc. adj. *omiyaensis* of or belonging to Omiya City near Tokyo, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (d. light gray, or 2dc, yellowish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (light yellow, pale yellow, or grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar or glycerol-asparagine agar.

D-Glucose, D-xylose, and rhamnose are utilized for growth. Only traces of growth are seen on L-arabinose or D-fructose; iso-inositol, D-mannitol, raffinose, and sucrose are not utilized.

Type strain shows the highest sequence similarity to: *S. exfoliatus*, AB184324, 99.6%; *S. wedmorensis*, DQ442557, 99.6%; *S. venezuelae*, AB045890, 99.6%; *S. zaomyceticus*, EF178685, 99.6%; *S. lateritius*, AB184324, 99.5%; *S. litmocidini*, AB184149, 99.5%; *S. yereyanensis* EF178684, 99.3%; *S. narbonensis*, DQ445794, 99.1%.

Source: isolated from soil from Omiya City near Tokyo, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 27454, CBS 750.72, BCRC 11897, DSM 40552, NBRC 13449, IMET 43362, JCM 4806, NRRL B-1587, NRRL-ISP 5552, RIA 1410, VKM Ac-1903.

Sequence accession no. (16S rRNA gene): EF178697.

359. **Streptomyces orinoci** (Cassinelli, Grein, Orezzi, Pennella and Sanfilippo 1967) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium orinoci* Cassinelli, Grein, Orezzi, Pennella and Sanfilippo 1967, 367)

o.ri.no′ci. N.L. gen. n. *orinoci* of Orinoco, named after the Orinoco River, South America, from whose banks it was isolated.

Spore chains in Section Umbellate Monoverticillate (=*Streptomyces* Section Verticillati, biverticillate). Mature spore chains generally contain more than 10 spores per chain. This morphology is usually seen on ISP yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but sporulating aerial mycelium may be observed in the scant growth on carbon-utilization medium enriched with raffinose, D-fructose, rhamnose, or iso-inositol or on half-strength Emerson potato-glucose agar. Spore surface is smooth.

Color of colony: sporulating aerial mycelium is not produced on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Aerial mass color on carbon-utilization medium plus fructose is in the Gray color series. Reverse side of colony is strong yellow or deep yellow on yeast-malt agar, glycerol-asparagine agar, and half-strength Emerson potato-glucose agar. Colorless to pale or grayish yellow on salts-starch agar and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose is utilized for growth. No growth or only traces of growth with L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose.

Type strain shows no sequence similarity over 99%.

Source: isolated from the banks of the Orinoco River, South America.

DNA G+C content (mol%): not known.

Type strain: ATCC 23202, CBS 767.72, CECT 3267, DSM 40571, IFM 1226, NBRC 13466, JCM 4546, JCM 4807, NRRL B-3379, NRRL-ISP 5571, RIA 1427, VKM Ac-929.

Sequence accession no. (16S rRNA gene): AB184866.

360. **Streptomyces pactum** (*sic*) Bhuyan, Dietz and Smith 1962, 185[AL]

pac′tum. L. adj. *pactum* settled (referring to the compactness of the coiled chains of spores).

Spore chains in Section *Spirales*. Mature spore chains contain 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but sporulation is usually poor on glycerol-asparagine agar. Spore surface is hairy.

Color of colony: aerial mass color in the Gray color series (d, light gray, or e, medium gray) on oatmeal agar and salts-starch agar; Gray or Blue color series on oatmeal agar. Nearest matching color tab in the Blue color series is 19fe, pale blue. On glycerol-asparagine agar, aerial mycelium is in the White color series. Reverse side of colony

with no distinctive pigments (light yellowish brown, grayish yellow or grayish greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose is utilized for growth and only traces of growth are reported with D-fructose. No growth with L-arabinose, D-xylose, iso-inositol, D-mannitol, rhamnose, sucrose, or raffinose.

Type strain shows the highest sequence similarity to: *S. olivaceus*, AB184743, 100%; *S. parvulus*, AB184326, 99.4%; *S. coeruleorubidus*, AY999719, 99.2%; *S. rubrogriseus*, AB184681, 99.2%; *S. lienomycini*, AJ781353, 99.2%; *S. malachitospinus*, AB249954, 99.2%; *S. anthocyanicus*, AB184631, 99.1%; *S. tricolor*, AB184687, 99.1%; *S. coelescens*, AF503496, 99%; *S. violaceoruber*, AF503492, 99%; *S. violaceorubidus*, AJ781374, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1443, ATCC 27456, CBS 461.69, CBS 734.72, BCRC 12076, DSM 40530, NBRC 13433, IMET 43357, JCM 4288, JCM 4809, KCTC 9165, LMG 19357, NCIMB 9445, NRRL 2939, NRRL-ISP 5530, RIA 1394, VKM Ac-1911.

Sequence accession no. (16S rRNA gene): AB184398.

361. **Streptomyces paradoxus** (Krasil'nikov and Yuan 1961) Goodfellow, Williams and Alderson 1986a, 575[VP] (Effective publication: Goodfellow, Williams and Alderson 1986e, 62.) (*Actinosporangium violaceum* Krasil'nikov and Yuan 1961, 115)

pa.ra′do.xus. L. masc. adj. *paradoxus* contrary to all expectation.

Spore chains in Section *Retinaculiaperti*. Spore surface is smooth. Forms extensively branched substrate and aerial mycelium. The aerial spore mass is gray; sclerotia are formed. Produces melanin pigments. Allantoin, adenine, esculin, arbutin, gelatin, guanine, hypoxanthine, testosterone, tyrosine, urea, and xanthine are degraded, but chitin, elastin, lecithin, pectin, and starch are not. Hydrogen sulfide is produced but nitrate is not reduced. L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, inulin, D-lactose, mannitol, D-mannose, melezitose, melibiose, raffinose, L-rhamnose, sucrose, trehalose, and D-xylose are used as sole carbon sources but adonitol and xylitol are not. Grows on L-arginine, L-cysteine, L-histidine, L-hydroxyproline, L-methionine, potassium nitrate, L-serine, L-threonine, and L-valine, but not on DL-amino-n-butyric acid or L-phenylalanine, as sole nitrogen sources. Grows at 10 and 37°C, but not at 4 or 45°C.Tolerant to phenol (0.1%, w/v) and sodium chloride (4%, w/v), but not sodium azide (0.01%, w/v). Sensitive to rifampin and inhibited by sodium chloride at 7% (w/v). Antimicrobial activity not shown against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046[T], *Saccharomyces cerevisiae* CBS 171, or *Streptomyces murinus* ISP 5091. The peptidoglycan contains LL-A_2pm as the major diamino acid and is of the A3γ type (Stackebrandt et al., 1981).

Type strain shows the highest sequence similarity to: *S. matensis*, AB184221, 99.6%; *S. collinus*, AB184123, 99.5%; *S. viridochromogenes*, DQ442555, 99.4%; *S. azureus*, EF178674, 99.3%; *S. griseoflavus*, AJ781322, 99.3%; *S. griseorubens*, AB184139, 99.3%; *S. bellus*, AB184849, 99.2%; *S. ambofaciens*, M27245, 99.2%; *S. glaucescens*, AB184843, 99.2%; *S. albaduncus*, AY999757, 99.2%; *S. erythrogriseus*, AJ781328, 99.2%; *S. labedae*, AB184704, 99.2%; *S. griseoincarnatus*, AJ781328, 99.2%; *S. variabilis*, DQ442551, 99.2%; *S. coerulescens*, AY999720, 99.2%; *S. violaceorubidus*, AJ781374, 99.1%; *S. flaveolus*, AB184764, 99.1%; *S. griseoloalbus*, AB184275, 99.1%; *S. capillispiralis*, AB184577, 99.1%; *S. althioticus*, AY999808, 99.1%; *S. pseudogriseolus*, DQ442541, 99%; *S. malachitofuscus*, AB184282, 99%; *S. levis*, AB184670, 99%.

Source: isolated from soil.

DNA G+C content (mol%): 70.4–71.6.

Type strain: ATCC 15813, BCRC 12521, DSM 43350, IFM 1160, NBRC 14887, IMET 43491, INMI 3180, JCM 3052, KCC A-0052, KCTC 9118, NRRL B-3457, NRRL B-3483, PCM 2310, RIA 655, VKM Ac-645.

Sequence accession no. (16S rRNA gene): AB184628.

362. **Streptomyces parvisporogenes** (Locci, Baldacci and Petrolini Baldan 1969) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium parvisporogenes* Locci, Baldacci and Petrolini Baldan 1969, 37)

par.vi.spo.ro′ge.nes. L. adj. *parvus* little; Gr. n. *spora* a seed and in biology a spore; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *parvisporogenes* producing a little number of spores.

Spore chains in Section Verticillate, umbellate monoverticillate (biverticillate). This morphology is seen on yeast-malt agar and oatmeal agar; a sporulating aerial mycelium is usually not produced on salts-starch agar and may also be absent on glycerol-asparagine agar. Spore surface is smooth or with some surface irregularities.

Color of colony: aerial mass color in the Red, White or Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The yellow color (1ba, 2ba, or 2db, pale yellow) is representative of aerial color in the absence of sporulation. Aerial mass color should be determined on a sporulating surface. Mature (21 d) sporulating aerial mycelium on oatmeal agar and on carbon-utilization medium plus fructose is in the Red color series (3ca, pale orange yellow). Reverse side of colony with no distinctive pigments (pale or grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; yellowish brown or olive brown on yeast-malt agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth; weakly or not at all in tyrosine agar. No pigment, or only a trace of yellow, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and iso-inositol are utilized for growth. Reports vary on utilization of D-mannitol, and utilization of D-fructose is doubtful. Only traces of growth are seen on L-arabinose, D-xylose, rhamnose, sucrose, and raffinose.

For sequence similarity, see type strain of *Streptomyces abikoensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 12568, CBS 695.72, DSM 40473, NBRC 13907, JCM 4694, JCM 4812, NRRL B-12386, NRRL B-5464, NRRL-ISP 5473, RIA 1355, VKM Ac-878.

Sequence accession no. (16S rRNA gene): AB249913.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces parvisporogenes* is proposed as a *nomen revictum* (basonym: "*Streptomyces parvisporogenes*" *ignotus* 1960).

According to Hatano et al. (2003), *Streptomyces parvisporogenes* (Locci et al. 1969) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces abikoensis* (Umezawa et al. 1951) Witt and Stackebrandt 1991.

363. **Streptomyces parvulus** corrig. Waksman and Gregory 1954, 1055[AL]

par'vu.lus. L. masc. adj. *parvulus* very small.

Spore chains in Section *Spirales*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow to grayed greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Variable reports on growth with raffinose.

Type strain shows the highest sequence similarity to: *S. pactum*, AB184398, 99.4%; *S. lomondensis*, AB184673, 99.3%; *S. olivaceus*, AB184743, 99.3%; *S. malachitospinus*, AB249954, 99.3%; *S. coeruleorubidus*, AY999719, 99.2%; *S. bellus*, AB184849, 99.2%; *S. coerulescens*, AY999720, 99.2%; *S. luteogriseus*, AB184379, 99.2%; *S. violaceorubidus*, AJ781374, 99.1%; *S. roseoviolaceus*, AJ399484, 99%; *S. lusitanus*, AB184424, 99%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99%; *S. spinoverrucosus*, AB184578, 99%; *S. janthinus*, AB184851, 99%; *S. violaceus*, AB184315, 99%; *S. tendae*, D63873, 99%; *S. purpurascens*, AJ399486, 99%.

Sequence accession no. (16S rRNA gene): AB184326.

Further comments: the original spelling, *Streptomyces parvullus* (*sic*), was corrected by Hill et al. (1984).

364. **Streptomyces parvus** (Krainsky 1914) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 939[AL] ("*Actinomyces parvus*" Krainsky 1914, 685; "*Nocardia parva*" Chalmers and Christopherson 1916, 268)

par'vus. L. masc. adj. *parvus* small.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally contain 10–50 or sometimes more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (1ba, 2ba, pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (light yellow to light greenish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. rubiginosohelvolus*, AB184240, 99.9%; *S. mediolani*, AB184674, 99.9%; *S. badius*, AY999783, 99.9%; *S. pluricolorescens*, DQ442540, 99.9%; *S. griseinus*, AB184205, 99.9%; *S. sindenensis*, AB184759, 99.9%; *S. flavofuscus*, AB249935, 99.8%; *S. globisporus* subsp. *globisporus*, EF178686, 99.8%; *S. griseoplanus*, AY999894, 99.8%; *S. praecox*, AB184293, 99.8%; *S. fimicarius*, AY999784, 99.8%; *S. albovinaceus*, AB249958, 99.8%; *S. anulatus*, DQ026637, 99.8%; *S. microflavus*, DQ445795, 99.7%; *S. cinereorectus*, AB184646, 99.7%; *S. lipmanii*, AB184148, 99.7%; *S. alboviridis*, AB184256, 99.7%; *S. floridae*, AB184656, 99.7%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.7%; *S. cyaneofuscatus*, AB184860, 99.7%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.7%; *S. fulvorobeus*, AB184711, 99.7%; *S. acrimycini*, AY999889, 99.7%; *S. californicus*, AB184755, 99.7%; *S. baarnensis*, EF178688, 99.7%; *S. argenteolus*, AB045872, 99.6%; *S. luridiscabiei*, AF361784, 99.5%; *S. flavogriseus*, AJ494864, 99.5%; *S. griseus* subsp. *griseus*, AY207604, 99.5%; *S. halstedii*, EF178695, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. griseolus*, AB184768, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. flavovirens*, DQ026635, 99.5%; *S. nitrosporeus*, EF178680, 99.4%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. finlayi*, AY999788, 99.3%; *S. yanii*, AB006159, 99.3%; *S. atroolivaceus*, AJ781320, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. olivoviridis*, AB184227, 99.3%; *S. clavifer*, DQ026670, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. atratus*, DQ026638, 99.2%; *S. griseobrunneus*, AB249912, 99.2%; *S. gelaticus*, DQ026636, 99.2%; *S. celluloflavus*, AB184476, 99.2%; *S. candidus*, DQ026663, 99.1%; *S. cremeus*, AB184124, 99%; *S. mutomycini*, AB249951, 99%; *S. spiroverticillatus*, AB184814, 99%.

Sequence accession no. (16S rRNA gene): DQ442537.

365. **Streptomyces paucisporeus** Xu, Wang, Cui, Huang, Liu, Zheng and Goodfellow 2006, 1113[VP]

pau.ci.spo′re.us. L. adj. *paucus* few; N.L. adj. *sporeus* spored; N.L. masc. adj. *paucisporeus* few spored, forming few spores.

Few spores with smooth surfaces are borne in short flexuous spore chains. Forms branched substrate and aerial hyphae. Khaki-colored colonies that carry a white to gray aerial spore mass are formed on acidified oatmeal agar, yeast extract-starch agar, and yeast extract-malt extract agar. Diffusible pigments are not formed, though melanin pigments are produced on tyrosine agar but not on peptone-yeast extract-iron agar. Degrades Tween 80, but not adenine, guanine, starch, or xanthine. Cellobiose, D-galactose, D-glucose, D-mannitol, D-sorbitol (each at 1%, w/v), L-alanine, L-arginine, α-L-aspartic acid, L-cysteine, L-glutamic acid, L-phenylalanine, and L-valine (each at 0.1%, w/v) are used as sole carbon sources for energy and growth, but adonitol, inulin, D-lactose (each at 1%, w/v), adipic acid, DL-aminobutyric acid, sodium acetate, sodium citrate, and sodium oxalate (each at 0.1%, w/v) are not. Does not use L-alanine, L-arginine, L-aspartic acid, L-glutamic acid, L-isoleucine, or L-phenylalanine (each at 0.1%, w/v) as sole carbon and nitrogen sources. Growth occurs at temperatures between 20 and 37°C, but not at 15°C, and at pH values from 4.5–7.5, but not at pH 3.5. Does not grow in the presence of 5% (w/v) NaCl. Sensitive to filter-paper discs soaked in the following (μg/ml unless indicated): azithromycin (30), doxycycline hydrochloride (30), erythromycin (15), josamycin (15), kanamycin sulfate (30), minocycline hydrochloride (30), neomycin sulfate (30), streptomycin sulfate (10), tetracycline hydrochloride (30), and tobramycin sulfate (10), but not to filter-paper discs soaked in acetylspiramycin (15), amoxycillin (10), ampicillin (10), azetreonam (30), carbenicillin (10), penicillin G (10 IU/ml), rifampin (5), or sulfamethoxazole (25). Chemotaxonomic properties are typical of the genus *Streptomyces.*

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. yeochonensis* NRRL B-24245^T, 35.0%; *S. guanduensis* JCM 13274^T, 14.9%; *S. rubidus* JCM 13277^T, 19.9%; *S. yanglinensis* JCM 13275^T, 25.9%.

Source: the type strain was isolated from Dahao pine-forest in Guandu, Yunnan Province, People's Republic of China.

DNA G+C content (mol%): 74.8.

Type strain: 1413, CGMCC 4.2025, JCM 13276.

Sequence accession no. (16S rRNA gene): AY876943.

366. **Streptomyces peucetius** Grein, Spalla, DiMarco and Canevazzi 1963, 109[AL]

peu.ce′ti.us. L. masc. adj. *peucetius* of or pertaining to Peucetia, an ancient name for Central Puglia in Italy, the source of the soil from which the organism was isolated.

Spore chains of atypical *Retinaculiaperti* type. Excellent growth on Czapek's solution agar; reported to form coremia; forms pinkish vegetative mycelium on some media. Produces daunomycin, an anti-bacterial and anti-tumor antibiotic; produces polyenic anti-fungal activity.

Type strain shows the highest sequence similarity to: *S. xantholiticus*, AB184349, 100%; *S. kurssanovii*, AB184325, 99.8%; *S. graminofaciens*, AJ781329, 99.7%.

Source: isolated from soil from Central Puglia, Italy.

DNA G+C content (mol%): not known.

Type strain: ATCC 29050, CCT 4840, CMI 101335, DSM 40754, JCM 9920, KCTC 9199, NBRC 100596, NCIMB 10972.

Sequence accession no. (16S rRNA gene): AB045887.

367. **Streptomyces phaeochromogenes** (Conn 1917) Waksman *in* Breed, Murray and Smith 1957, 778[AL] ["*Actinomyces pheochromogenus*" (*sic*) Conn 1917, 16; "*Streptomyces phaeochromogenus*" (*sic*) Waksman and Henrici 1948, 943; "*Streptomyces pheochromogenus*" Pridham, Hesseltine and Benedict 1958, 74]

pha.e.o.chro.mo′ge.nes. Gr. adj. *phaios* brown; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *phaeochromogenes* producing brown color.

Spore chains in Section *Rectiflexibiles.* Mature spore chains are generally straight chains of 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spirals were reported in Waksman's (1919) description, but not in Conn's original description (Conn, 1917; op. cit). Spore surface is smooth.

Color of colony: aerial mass color usually in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Most representative color-tabs from the Red color series were 3ca (pale orange yellow) and 5ca or 5cb (light yellowish pink to grayish yellowish pink). Aerial mass color may also be white or pale yellow on oatmeal agar and pale yellow on salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale yellow or grayish yellow on oatmeal agar and salts-starch agar; light brown to strong brown on glycerol-asparagine agar and yeast-malt agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment other than trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on utilization of raffinose.

Type strain shows the highest sequence similarity to: *S. ederensis*, AB184658, 99.6%; *S. umbrinus*, AB184305, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23945, ATCC 3338, CBS 282.30, CBS 288.60, CBS 929.68, BCRC 12484, CECT 3070, DSM 40073, IFM 1051, NBRC 12898, NBRC 3180, IMET 40355, JCM 4070, JCM 4659, KCTC 9763, LMG 19348, NCIMB

8505, NRRL B-1248, NRRL B-3010, NRRL-ISP 5073, RIA 1119, RIA 61, VKM Ac-1002.

Sequence accession no. (16S rRNA gene): AB184738.

368. **Streptomyces phaeofaciens** Maeda, Okami, Kosaka, Taya and Umezawa 1952, 327[AL]

pha.e.o.fa'ci.ens. Gr. adj. *phaios* brown; L. part adj. *faciens* producing; N.L. part adj. *phaeofaciens* producing brown, referring to production of brown diffusible pigment.

Spore chains in Section *Spirales*. Mature spore chains are long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color usually in the Gray color series (3ih, dark gray; 3ig, grayish yellowish brown; 3ge, light grayish yellowish brown; or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; the yellow to reddish brown aerial mycelium may also fall in the Red color series as represented by color tab 4ge, light grayish reddish brown. Reverse side of colony with no distinctive pigments (greenish yellow to light olive brown on yeast-malt agar; pale yellow to light olive gray on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but are formed only weakly or as trace amounts in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with sucrose or raffinose.

Type strain shows the highest sequence similarity to: *S. phaeofaciens*, AB184360, 100%; *S. rishiriensis*, EF178691, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 15034, CBS 426.64, CBS 673.72, DSM 40367, IFM 1177, NBRC 13372, JCM 4125, JCM 4814, NRRL B-1516, NRRL-ISP 5367, RIA 1333, VKM Ac-1865.

Sequence accession no. (16S rRNA gene): AB184360.

369. **Streptomyces phaeogriseichromatogenes** Goodfellow, Kumar, Labeda and Sembiring 2008, 1[VP] (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 194.)

pha.e.o.gri.se.i.chro.ma.to'ge.nes. Gr. adj. *phaios* brown; N.L. adj. *griseus* gray; Gr. n. *chroma -atos* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *phaeogriseichromatogenes* producing brown and gray colors.

Spore chains are *Rectiflexibiles*; spore surface is ridged. Aerial spore mass colors range from grayish-white to grayish-brown and substrate mycelium is yellow to yellowish-brown, a yellow diffusible pigment is formed on yeast extract-malt extract agar, but melanin pigments are not produced. Hydrogen sulfide is produced, esculin is hydrolyzed, but not urea. Nitrate is not reduced. Casein, chitin, hypoxanthine, tyrosine, Tween 60, uric acid, and xanthine are degraded, but not adenine, arbutin, guanine, or xylan. L-Arabinose, D-arabitol, butan-1,4-diol, cellobiose, citric acid, dextrin, D-fructose, D-galactose, D-glucose, α-lactose, maltose, D-mannitol, D-mannose, D-ribose, and D-sucrose are used as sole carbon sources, but not L-arabitol, L-fucose, *myo*-inositol, melezitose, methanol, propanol, pyruvic acid, raffinose, L-rhamnose, or salicin. L-Alanine, L-arginine, L-glutamic acid, L-histidine, L-leucine, DL-methionine, DL-norleucine, L-proline, and L-valine are used as sole carbon and nitrogen sources, but not α-alanine, L-aminobutyric acid, L-glycine, L-phenylalanine, L-threonine, or L-tryptophan. Grows from pH 5 to pH 10, at 25 and 37°C, but not at 10 or 40°C. Does not grow in the presence of 13% (w/v) NaCl. Resistant (μg/ml) to cephalosporin (32), cefoxitin (32), cephaloridine (32, 64), doxycycline hydrochloride (4), and rifampin (64), but not to cefoxitin (64), carbenicillin (32, 64), erythromycin (32, 64), oleandomycin phosphate (32, 64), chlortetracycline hydrochloride (4, 8), doxycycline hydrochloride (8), rifampin (32, 64), fusidic acid (8, 16), lincomycin hydrochloride (32, 64), or novobiocin (4, 8).

Type strain shows the highest sequence similarity to: *S. costaricanus*, AB249939, 99.6%; *S. griseofuscus*, AB184206, 99.6%; *S. murinus*, AB184155, 99.6%.

Source: not known.

DNA G+C content (mol%): 71.2.

Type strain: DSM 40710, NRRL 2834.

Sequence accession no. (16S rRNA gene): AJ391813.

370. **Streptomyces phaeoluteichromatogenes** Goodfellow, Kumar, Labeda and Sembiring 2008, 1[VP] (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 195.)

pha.e.o.lu.te.i.chro.ma.to'ge.nes. Gr. adj. *phaios* brown, dark; L. adj. *luteus* yellow; Gr. n. *chroma -atos* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *phaeoluteichromatogenes* producing brown and yellow colors.

Spore chains are *Rectiflexibiles*; spore surface is smooth. On oatmeal agar the aerial spore mass color is brown and the substrate mycelium is yellow; a yellow diffusible pigment is produced. Melanin pigments are not formed. Esculin and urea are hydrolyzed. Does not produce hydrogen sulfide or reduce nitrate. Adenine, casein, chitin, hypoxanthine, tyrosine, and Tween 80 are degraded, but not casein, guanine, uric acid, xanthine, or xylan. Uses L-arabinose, D- and L-arabitol. butan-1,4-diol, cellobiose, citric acid, D-fructose, D-galactose, D-glucose, *myo*-inositol, D-mannitol, D-mannose, melezitose, methanol, propanol, and pyruvic acid as sole carbon sources, but not dextrin, L-fucose, α-lactose, maltose, raffinose, L-rhamnose, D-ribose, D-salicin, or sucrose. α-Alanine, L-glutamic acid, L-glycine, L-leucine, L-proline, L-serine, and L-threonine are used as sole carbon and nitrogen sources, but not L-alanine, L-aminobutyric acid, L-histidine, DL-methionine, DL-norleucine, L-phenylalanine, L-tryptophan, or L-valine. Grows from pH 4 to pH 9 and at 25°C and 40°C, but not at 10°C. Growth occurs in the presence of 13% (w/v) NaCl. Resistant (μg/ml) to carbenicillin (32, 64), cephalosporin (32), cefoxitin (32, 64), cephaloridine (32, 64),

chlortetracycline hydrochloride (4, 8), doxycycline hydrochloride (4, 8), tetracycline hydrochloride (64), rifampin (32, 64), and novobiocin (4), but sensitive to erythromycin (32, 64), oleandomycin phosphate (32, 64), fusidic acid (8, 16), and lincomycin hydrochloride (32, 64).

Type strain shows the highest sequence similarity to: *S. misionensis*, EF178678, 99.8%; *S. diastaticus* subsp. *diastaticus*, AB184785, 99.1%; *S. rutgersensis* subsp. *rutgersensis*, AB184170, 99.1%; *S. gougerotii*, AB184742, 99.1%; *S. intermedius*, AB184277, 99%.

Source: not known.

DNA G+C content (mol%): 69.8.

Type strain: DSM 41898, NRRL B-5799.

Sequence accession no. (16S rRNA gene): AJ391814.

371. **Streptomyces phaeoluteigriseus** Goodfellow, Kumar, Labeda and Sembiring 2008, 1[VP] (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 196.)

pha.e.o.lu.te.o.gri′se.us. Gr. adj. *phaios* brown; L. adj. *luteus* yellow; N.L. adj. *griseus* gray; N.L. masc. adj. *phaeoluteigriseus* brown, yellow, and gray-colored.

Spore chains are *Rectiflexibiles*; spore surface is smooth. On oatmeal agar the aerial spore mass color is gray and the substrate mycelium is yellowish-brown; a yellow diffusible pigment is produced, as are melanin pigments. Esculin is hydrolyzed but not urea. Hydrogen sulfide is produced, but nitrate is not reduced. Adenine, arbutin, chitin, hypoxanthine, Tween 80, and xanthine are degraded, but not arbutin, guanine, tyrosine, uric acid, or xylan. Adonitol, L-arabitol, citric acid, and dextrin are used as sole carbon sources, but not L-arabitol, butan-1,4-diol, cellobiose, D-fructose, L-fucose, D-galactose, D-glucose, *myo*-inositol, α-lactose, D-mannitol, D-mannose, melezitose, methanol, propanol, pyruvic acid, raffinose, L-rhamnose, D-ribose, salicin, or sucrose. α-Alanine, L-histidine, and L-threonine are used as sole carbon and nitrogen sources, but not L-alanine, L-aminobutyric acid, L-arginine, L-glutamic acid, L-leucine, DL-methionine, DL-norleucine, L-phenylalanine, L-serine, L-threonine, L-tryptophan, or L-valine. Grows from pH 4 to pH 10 and at 25 and 37°C, but not at 10 or 40°C. Growth occurs in the presence of 13% (w/v) NaCl. Resistant (μg/ml) to carbenicillin (32, 64), cefocitin (32, 64), cephaloridine (32), oleandomycin phosphate (32), chlortetracycline hydrochloride (4), tetracycline hydrochloride (64), fusidic acid (8, 16), and novobiocin (4), but sensitive to cephalosporin (32), cephaloridine (64), erythromycin (32, 64), oleandomycin phosphate (64), chlortetracycline hydrochloride (8), doxycycline hydrochloride (4, 8), rifampin (32, 64), lincomycin hydrochloride (32, 64), and novobiocin (8).

Type strain shows the highest sequence similarity to: *S. bobili*, AB249925, 99.5%; *S. novaecaesareae*, AB184357, 99.5%; *S. galilaeus*, AB045878, 99.5%; *S. pseudovenezuelae*, AB184233, 99.4%; *S. resistomycificus*, AB184166, 99.4%; *S. chartreusis*, AB184839, 99.1%; *S. prunicolor*, DQ026659, 99%.

Source: not known.

DNA G+C content (mol%): 72.2.

Type strain: DSM 41896, ISP 5182, NRRL ISP-5182.

Sequence accession no. (16S rRNA gene): AJ391815.

372. **Streptomyces phaeopurpureus** Shinobu 1957, 63[AL] emend. Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2004, 88.)

pha.e.o.pur.pu′re.us. Gr. adj. *phaios* brown; L. adj. *purpureus* purple colored; N.L. masc. adj. *phaeopurpureus* brown, purple colored.

Spore chains in Section *Rectiflexibiles*. Aerial mycelium is usually poorly developed or absent on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Mature spore chains may be observed on other media including Gause's medium no. 1 where chains of 10 to 50 or more spores may be formed. Spore surface is smooth.

Color of colony: aerial mass color probably in the Gray or Red color series, but aerial sporulation on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar is usually inadequate for accurate spore mass color determination. Reverse side of colony is yellow to yellow brown modified by red (light brown, strong brown, or grayish reddish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; moderate to strong reddish brown on yeast-malt agar). Substrate mycelium pigment is not a pH indicator (or is changed only slightly from brown to yellow brown by 0.05 M HCl).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow, orange, or red pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is slightly pH-sensitive changing from reddish orange or brown to yellow brown with 0.05 M HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. griseorubiginosus*, AJ781339, 100%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23946, CBS 930.68, BCRC 13754, DSM 40125, HAMBI 950, NBRC 12899, NBRC 3930, JCM 4101, JCM 4660, KCTC 9764, NRRL B-2260, NRRL-ISP 5125, RIA 1128.

Sequence accession no. (16S rRNA gene): DQ026666.

Further comments: according to Lanoot et al. (2004), *Streptomyces phaeopurpureus* Shinobu 1957 is an earlier heterotypic synonym of *Streptomyces phaeoviridis* Shinobu 1957.

373. **Streptomyces phaeoviridis** Shinobu 1957, 63[AL]

pha.e.o.vi′ri.dis. Gr. adj. *phaios* brown; L. adj. *viridis* green; N.L. masc. adj. *phaeoviridis* brown-green.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar and salts-starch agar, but aerial mycelium with mature spore chains is not formed on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar and salts-starch

agar. (White also may be seen on these media and on the poorly sporulated surface of glycerol-asparagine agar) Reverse side of colony is yellow to yellow brown is modified slightly by red or orange (light yellowish brown to strong brown, yellowish pink, or grayish reddish orange). Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar and tryptone-yeast broth. Orange or reddish pigment is found in the medium in yeast-malt agar, oatmeal agar and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl. D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose and raffinose are utilized for growth.

For sequence similarity, see type strain of *Streptomyces phaeopurpureus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23947, CBS 931.68, DSM 40285, NBRC 12900, JCM 4102, JCM 4661, NCIMB 9832, NRRL B-2258, NRRL-ISP 5285, RIA 1199.

Sequence accession no. (16S rRNA gene): AB184230.

Further comments: according to Lanoot et al. (2004), *Streptomyces phaeoviridis* Shinobu 1957 is a later heterotypic synonym of *Streptomyces phaeopurpureus* Shinobu 1957.

374. **Streptomyces pharetrae** Le Roes and Meyers 2005a, 2236[VP] (Effective publication: Le Roes and Meyers 2005b, 489.)

pha.re′tra.e. L. gen. n. *pharetrae* of a quiver for holding arrows, isolated from soil taken from the base of a Giant quiver tree (*Aloe pillansii*).

Aerobic, Gram-stain-positive actinomycete which forms green aerial mycelium and yellow-blue substrate mycelium on ISP 4 (inorganic salts-starch agar). The color of the substrate mycelium is not pH-sensitive. No fragmentation occurs and no verticils are present. Mature spore chains are of the *Spirales*-type with hairy spore ornamentation. Spores are nonmotile. Good growth is observed on Czapek's solution agar, yeast extract-malt extract agar (ISP 2), and inorganic salts-starch agar (ISP 4). Substrate mycelium color is medium-dependent, but aerial mycelium color is constant. No diffusible pigment is produced on glycerol-asparagine agar (ISP 5). Melanin is produced on peptone-yeast extract-iron agar (ISP 6), but not on tyrosine agar (ISP 7). H_2S production occurs and nitrate is reduced (weak reaction after 14 d). Lecithinase, protease, and lipase activities are observed on egg-yolk agar. Pectin is hydrolyzed but not hippurate. Degrades adenine, esculin, arbutin, casein, cellulose, gelatin, hypoxanthine, L-tyrosine, Tween 80, and urea. Starch hydrolysis is negative at 7 d, but weakly positive when tested at 14 and 21 d. Allantoin, guanine, xanthine, and xylan are not degraded. Uses β-alanine, DL-alanine, ammonium phosphate, L-arginine, L-asparagine, L-cysteine, L-glutamic acid, L-glutamine, L-histidine, L-hydroxyproline, L-isoleucine, L-leucine, L-methionine, L-phenylalanine, potassium nitrate, L-proline, L-serine, urea, and L-valine, but not DL-α-amino-*n*-butyric acid as sole nitrogen sources. Uses dextran, D(−) fructose, D(+)glucose, methyl α-D-glucoside, glycerol, glycogen, D(−)ribose, sodium butyrate, and sodium sorbate as sole carbon sources, but not adonitol, *meso*-erythritol, *myo*-inositol, inulin, maltose, D(+)melibiose, D(+)melezitose, raffinose, salicin, sodium benzoate, sodium formate, sodium lactate, sodium maleate, sodium oxalate, sodium salicylate, sodium L(+)tartrate, trehalose, or xylitol. Weak growth is observed after 21 d on L(+)arabinose, D(−)lactose, D(−)mannitol, D(+)mannose, L(+)rhamnose, sodium acetate, sodium citrate, sodium gluconate, sodium DL-malate, sodium succinate, sucrose, and D(+)xylose. Grows in the presence of 0.3% 2-phenylethanol, 0.0001% crystal violet, 7% NaCl (but not 10%), and 0.1% phenol, but not in the presence of sodium azide (0.01%). Growth is also observed in the presence of cephaloridine (100 μg/ml), lincomycin (100 μg/ml), penicillin G (10 IU/ml), and rifampin (50 μg/ml), but not in the presence of neomycin (50 μg/ml), and streptomycin (100 μg/ml). Growth is observed at 30, 37, and 45°C, but not at 4°C or at pH 4.3. Weak antibiosis is exhibited against *Bacillus coagulans* ATCC 7050[T], *Mycobacterium aurum* A+, and *Acinetobacter colcoaceticus* C91, but there is no antibiosis against *Escherichia coli* ATCC 25922, *Pseudomonas aeruginosa* ATCC 27853, and *Staphylococcus aureus* ATCC 25923.

Type strain shows the highest sequence similarity to: *S. glaucescens*, AB184843, 99.3%.

Source: isolated from soil taken from the base of a Giant quiver tree (*Aloe pillansii*).

DNA G+C content (mol%): 76.0 (±1.4).

Type strain: CZA14, DSM 41856, JCM 13860, NRRL B-24333.

Sequence accession no. (16S rRNA gene): AY699792.

375. **Streptomyces pilosus** Ettlinger, Corbaz and Hütter 1958a, 347[AL]

pi.lo′sus. L. masc. adj. *pilosus* hairy, shaggy.

Spore chains in Section *Rectiflexibiles* to *Spirales*. Short spore chains include straight or flexuous chains, hooks, loops, and poorly developed spirals. Hooks and loops of small diameter on short sporophores are not typical of the broad hooks and loops of *Retinaculiaperti* cultures. In the original description (Ettlinger et al., 1958a), spore chains are described as open, regular spirals. Mature spore chains are moderately short with 3–10 or sometimes more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar; sporulation may be poor on glycerol-asparagine agar. Spore surface is hairy, with a tendency toward spines on some spores.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony is grayed yellow to yellow-brown on glycerol-asparagine agar and dark grayed yellow-brown to near black on yeast-malt agar, oatmeal agar, and salts-starch agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast extract broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. flavoviridis*, AB184842, 100%; *S. violaceus*, AB184315, 99.2%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.2%; *S. janthinus*, AB184851, 99.2%; *S. lomondensis*, AB184673, 99.2%; *S. geysiriensis*, DQ442501, 99.2%; *S. minutiscleroticus*, EF178696, 99.2%; *S. roseoviolaceus*, AJ399484, 99.2%; *S. ghanaensis*, AY999851, 99.2%; *S. luteogriseus*, AB184379, 99.2%; *S. djakartensis*, AB184657, 99.1%; *S. plicatus*, AB184291, 99.1%; *S. rochei*, AB184237, 99.1%; *S. vinaceusdrappus*, AY999929, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. hawaiiensis*, AB184143, 99%; *S. atrovirens*, DQ026672, 99%; *S. arenae*, AB249977, 99%; *S. calvus*, AB184329, 99%; *S. tuirus*, AB184690, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 19797, CBS 549.68, BCRC 12091, DSM 40097, NBRC 12807, JCM 4403, NRRL 2721, NRRL-ISP 5097, RIA 1076, UNIQEM 183, VKM Ac-1765.

Sequence accession no. (16S rRNA gene): AB184161.

376. **Streptomyces platensis** Tresner and Backus 1956, 244[AL]

plat.en′sis. Gr. adj. *platus* flat, broad, wide; N.L. masc. adj. *platensis* belonging to flat.

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spores frequently coalesce to form black, moist (hygroscopic) masses of spores. Sometimes much of the aerial growth will be converted to a black, moist surface. Reverse side of colony is grayish yellow on oatmeal agar and salts-starch agar; sometimes modified by red to grayish yellowish pink or light reddish brown on yeast-malt agar and glycerol-asparagine agar. Reddish substrate mycelium pigment may be changed to colorless or pale yellow by 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Traces of red or yellow pigments are found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. The reddish pigment is somewhat pH-sensitive, changing from grayed red to nearly colorless with 0.05 M HCl.

D-Glucose, sucrose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Utilization of L-arabinose and D-xylose is doubtful. No growth or only trace of growth with rhamnose.

Type strain shows the highest sequence similarity to: *S. libani* subsp. *rufus*, AJ781351, 99.9%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.9%; *S. caniferus*, AB184640, 99.8%; *S. libani* subsp. *libani*, AB184414, 99.5%; *S. nigrescens*, DQ442530, 99.5%; *S. tubercidicus*, AJ621612, 99.5%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.4%; *S. misakiensis*, AB217605, 99.2%; *S. catenulae*, AJ621613, 99.2%; *S. ramulosus*, DQ026662, 99.1%; *S. sioyaensis*, DQ026654, 99.1%; *S. monomycini*, DQ445790, 99%.

Sequence accession no. (16S rRNA gene): AB045882.

377. **Streptomyces plicatus** Pridham, Hesseltine and Benedict 1958, 65[AL]

pli.ca′tus. L. masc. part. adj. *plicatus* folded, coiled.

Spore chains in Section *Spirales*. Spirals are characteristically open. Wavy spore chains or long flexuous chains terminating in hooks, loops, or incomplete spirals may also suggest *Retinaculiaperti* morphology. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color usually in the Gray color series (3fe, light brownish gray or 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but color similar to 5dc (grayish yellowish pink) from the Red color series may also be seen on yeast-malt agar and salts-starch agar. Reverse side of colony with no distinctive pigments (pale grayish yellow, yellowish brown or occasionally dark grayish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth with sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. vinaceusdrappus*, AY999929, 100%; *S. ghanaensis*, AY999851, 100%; *S. geysiriensis*, DQ442501, 100%; *S. minutiscleroticus*, EF178696, 100%; *S. rochei*, AB184237, 100%; *S. mutabilis*, EF178679, 99.9%; *S. tuirus*, AB184690, 99.5%; *S. djakartensis*, AB184657, 99.4%; *S. anandii*, AB184402, 99.2%; *S. violaceorubidus*, AJ781374, 99.2%; *S. pilosus*, AB184161, 99.1%; *S. flavoviridis*, AB184842, 99.1%; *S. tendae*, D63873, 99%; *S. calvus*, AB184329, 99%; *S. azureus*, EF178674, 99%; *S. asterosporus*, AB184706, 99%; *S. levis*, AB184670, 99%; *S. luteogriseus*, AB184379, 99%; *S. capillispiralis*, AB184577, 99%.

Sequence accession no. (16S rRNA gene): AB184291.

378. **Streptomyces pluricolorescens** Okami and Umezawa *in* Waksman 1961, 259[AL]

plu.ri.co.lor.es′cens. L. comp. adj. *plus, pluris* more, many; L. n. *color* color; N.L. part. adj. *pluricolorescens* becoming many-colored or variegated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately short with 3–10, or sometimes more than 10 spores per chain. This morphology is observed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (usually pale yellow in 7 d becoming pale orange-yellow or grayish yellowish pink in 14–21 d). Reverse side of colony is grayed yellow to yellow-brown (modified slightly by red in 14–21 d) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, and raffinose. Utilization of L-arabinose is doubtful.

Type strain shows the highest sequence similarity to: *S. sindenensis*, AB184759, 100%; *S. albovinaceus*, AB249958, 100%; *S. griseoplanus*, AY999894, 100%; *S. anulatus*, DQ026637, 100%; *S. globisporus* subsp. *globisporus*, EF178686, 100%; *S. praecox*, AB184293, 100%; *S. flavofuscus*, AB249935, 100%; *S. fimicarius*, AY999784, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. griseinus*, AB184205, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. californicus*, AB184755, 99.9%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.9%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.9%; *S. acrimycini*, AY999889, 99.9%; *S. parvus*, DQ442537, 99.9%; *S. fulvorobeus*, AB184711, 99.8%; *S. lipmanii*, AB184148, 99.8%; *S. microflavus*, DQ445795, 99.8%; *S. cyaneofuscatus*, AB184860, 99.8%; *S. floridae*, AB184656, 99.8%; *S. alboviridis*, AB184256, 99.8%; *S. baarnensis*, EF178688, 99.8%; *S. cinereorectus*, AB184646, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. bacillaris*, AB184439, 99.6%; *S. pulveraceus*, AB184806, 99.6%; *S. halstedii*, EF178695, 99.6%; *S. flavogriseus*, AJ494864, 99.6%; *S. atroolivaceus*, AJ781320, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. albolongus*, AB184425, 99.4%; *S. clavifer*, DQ026670, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. sanglieri*, AB249945, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. yanii*, AB006159, 99.4%; *S. gelaticus*, DQ026636, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. mutomycini*, AB249951, 99.2%; *S. candidus*, DQ026663, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cremeus*, AB184124, 99.1%.

Type strain: ATCC 19798, CBS 550.68, BCRC 13657, DSM 40019, IFM 1101, NBRC 12808, JCM 4302, JCM 4602, NCIMB 9813, NRRL B-2121, NRRL-ISP 5019, RIA 1077, UNIQEM 184, VKM Ac-765.

Sequence accession no. (16S rRNA gene): DQ442540.

379. **Streptomyces polychromogenes** Hagemann, Pénasse and Teillon *in* Hütter 1964, 615[AL]

po.ly.chro.mo′ge.nes. Gr. adj. *polu* many; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *polychromogenes* producing many colors, referring to the characteristic variation of pigmentation.

Spore chains characteristically in Section *Rectiflexibiles* with long, straight spore chains of more than 50 spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. A few spore chains may terminate in spirals. Spore surface is smooth. Knots and nest-like tangles may be seen in the aerial mycelium. Some of these tangles fragment into spore-like bodies and one observer reports that spores may also be seen on the substrate mycelium.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (nearly colorless to grayish yellow or light yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; light grayish reddish brown to strong brown on yeast-malt agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but only weakly or not at all in tyrosine agar. No pigment, or only a trace of yellow, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, and sucrose are utilized for growth. Only traces of growth is seen with iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. racemochromogenes*, DQ026656, 100. *S. flavotricini*, AB184132, 99.7. *S. katrae*, AB184409, 99.5. *S. cinnamonensis*, AB184707, 99.1. *S. tanashiensis*, AJ781362, 99.1. *S. globosus*, AJ781330, 99.1. *S. nojiriensis*, AJ781355, 99. *S. spororaveus*, AJ781370, 99. *S. toxytricini*, DQ442548, 99. *S. nashvillensis*, AB184286, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 12595, ATCC 25484, CBS 311.56, CBS 912.69, BCRC 11899, DSM 40316, NBRC 13072, JCM 4236, JCM 4505, KCTC 9765, NCIMB 8791, NRRL B-12233, NRRL B-2656, NRRL B-3032, NRRL B-5697, NRRL-ISP 5316, RIA 1264, RIA 362, VKM Ac-1207.

Sequence accession no. (16S rRNA gene): AB184292.

380. **Streptomyces poonensis** (Thirumalachar *in* Kalakoutskii and Krasil'nikov *in* Rautenshtein 1960) Pridham 1970, 42[AL] ("*Chainia poonensis*" Thirumalachar *in* Kalakoutskii and Krasil'nikov *in* Rautenshtein 1960, 45)

po.on.en′sis. N.L. masc. adj. *poonensis* of or belonging to Poona, India, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*. Mature spore chains generally contain 3 to 10 or more spores per chain. Aerial mycelium may be absent or spiral spore chains may be seen on yeast-malt agar and salts-starch agar. Straight spore chains are reported on oatmeal agar. Spore surface is smooth. Sclerotia are abundant on yeast-malt agar, oat-

meal agar, salts-starch agar, and glycerol-asparagine agar in 14 d. One observer reports LL-A_2pm and no arabinose in the cell wall, placing this strain in cell-wall type I.

Color of colony: aerial mass color in the White color series on yeast-malt agar, oatmeal agar, and salts-starch agar when aerial mycelium is produced. Aerial mycelium is usually not seen on glycerol-asparagine agar and may be absent on oatmeal agar or other ISP media. Reverse side of colony is colorless on glycerol-asparagine agar; yellow to yellow brown is modified by red becoming reddish brown, brownish pink, or purplish pink on yeast-malt agar, oatmeal agar, and salts-starch agar within 21 d. Only one of three observers reports reverse mycelium pigment is pH-sensitive, changing from pink to violet with the addition of 0.05 M NaOH.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Two observers report no pigment in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer reports pinkish pigment in yeast-malt agar, oatmeal agar, and salts-starch agar; it is reported that this pigment is pH-sensitive, changing from pink to violet with the addition of 0.05 M NaOH.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, and D-fructose are utilized for growth. Reports vary on utilization of rhamnose; no growth or only traces of growth with sucrose or raffinose.

Type strain shows the highest sequence similarity to: *S. fumigatiscleroticus*, DQ442499, 99.3%; *S. ruber*, AB184604, 99.1%.

Source: isolated from soil from Poona, India.

DNA G+C content (mol%): not known.

Type strain: AS 4.1097, ATCC 15723, CBS 295.66, CBS 786.72, BCRC 13311, DSM 40596, HAMBI 987, NBRC 12556, NBRC 13485, IMET 43406, JCM 3071, JCM 3079, JCM 4815, LMG 19326, NRRL B-2319, NRRL B-2951, NRRL-ISP 5596, PCM 2246, RIA 1446, RIA 569, VKM Ac-1715.

Sequence accession no. (16S rRNA gene): DQ445792.

Further comments: Streptomyces poonensis (Thirumalachar 1960) Pridham 1970 and *Chainia poonensis* Thirumalachar 1960 have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b (1) of the *Bacteriological Code* (1990 Revision)].

381. **Streptomyces praecox** (Millard and Burr 1926) Waksman *in* Waksman and Lechevalier 1953, 107[AL] ("*Actinomyces praecox*" Millard and Burr 1926, 633)

pra.e′cox. L. masc. adj. *praecox* premature, precocious.

Spore chains predominantly in Section *Rectiflexibiles* on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One of three ISP observers records strongly flexuous chains on yeast-malt agar to open spirals on oatmeal agar in 14 d. The original work of Millard and Burr (op. cit) describes "widely open spirals". Spore chains are moderately long with 10–50 or sometimes more than 50 spores per chain. Spore surface is smooth.

Color of colony: mature aerial mass color in the Yellow color series (pale yellow or pale yellow-green) on yeast-malt agar, oatmeal agar, and salts-starch agar; White color series on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow to light olive-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment, or only a trace of yellow, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of iso-inositol, sucrose, and raffinose is doubtful.

Type strain shows the highest sequence similarity to: *S. flavofuscus*, AB249935, 100%; *S. lavendulae* subsp. *lavendulae*, AB184080, 100%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 100%; *S. anulatus*, DQ026637, 100%; *S. acrimycini*, AY999889, 100%; *S. griseinus*, AB184205, 100%; *S. fimicarius*, AY999784, 100%; *S. badius*, AY999783, 100%; *S. griseoplanus*, AY999894, 100%; *S. mediolani*, AB184674, 100%; *S. sindenensis*, AB184759, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. globisporus* subsp. *globisporus*, EF178686, 99.9%; *S. alboviridis*, AB184256, 99.9%; *S. lipmanii*, AB184148, 99.9%; *S. fulvorobeus*, AB184711, 99.9%; *S. cyaneofuscatus*, AB184860, 99.9%; *S. albovinaceus*, AB249958, 99.9%; *S. cinereorectus*, AB184646, 99.9%; *S. microflavus*, DQ445795, 99.9%; *S. baarnensis*, EF178688, 99.9%; *S. californicus*, AB184755, 99.8%; *S. parvus*, DQ442537, 99.8%; *S. argenteolus*, AB045872, 99.8%; *S. flavovirens*, DQ026635, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. flavogriseus*, AJ494864, 99.7%; *S. halstedii*, EF178695, 99.7%; *S. floridae*, AB184656, 99.7%; *S. pulveraceus*, AB184806, 99.5%; *S. clavifer*, DQ026670, 99.5%; *S. atroolivaceus*, AJ781320, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. bacillaris*, AB184439, 99.5%; *S. yanii*, AB006159, 99.4%; *S. celluloflavus*, AB184476, 99.3%; *S. griseobrunneus*, AB249912, 99.3%; *S. sanglieri*, AB249945, 99.3%; *S. albolongus*, AB184425, 99.3%; *S. mutomycini*, AB249951, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. gelaticus*, DQ026636, 99.3%; *S. spiroverticillatus*, AB184814, 99.2%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. candidus*, DQ026663, 99.1%; *S. mauvecolor*, AB184532, 99%; *S. cremeus*, AB184124, 99%.

Sequence accession no. (16S rRNA gene): AB184293.

382. **Streptomyces prasinopilosus** Ettlinger, Corbaz and Hütter 1958a, 345[AL]

pra.si.no.pi.lo′sus. L. adj. *prasinus* green; L. adj. *pilosus* hairy; N.L. masc. adj. *prasinopilosus* green-hairy.

Spore chains in Section *Retinaculiaperti*. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is hairy.

Color of colony: aerial mass color in the Green color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow or grayed greenish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar, and grayed yellow modified by orange on yeast-malt agar. Substrate pigment is not a pH indicator (one observer reports slight change form orange to brown with NaOH).

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose. Variable reports on growth with D-xylose and D-mannitol.

Type strain shows the highest sequence similarity to: *S. emeiensis*, DQ462649, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19799, CBS 551.68, BCRC 13678, DSM 40098, NBRC 12809, JCM 4207, JCM 4404, LMG 19345, NCIMB 9842, NRRL B-2711, NRRL-ISP 5098, RIA 1078, UNIQEM 185, VKM Ac-1740.

Sequence accession no. (16S rRNA gene): EF626597.

383. **Streptomyces prasinosporus** Tresner, Hayes and Backus 1966, 162[AL]

pra.si.no′spo.rus. L. adj. *prasinus* green; N.L. n. *spora* a spore; N.L. masc. adj. *prasinosporus* green-spored.

Spore chains in Section *Spirales* with irregular spirals of a few turns and loops and hooks of small diameter. Spirals are often clumped or tangled. Mature spore chains are generally short with 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is hairy, with short hairs.

Color of colony: aerial mass color usually in the Green color series when good sporulation occurs on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (1li, olive gray; 1ig, light grayish olive, or 24½ih, dark greenish gray). Aerial mass color may also be in the Gray color series (2ih, light olive gray or, if sporulating aerial mycelium is less developed, g, medium gray or 2dc, yellowish gray). Reverse side of colony with no distinctive pigments (pale yellow to light olive gray on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; grayish greenish yellow on yeast-malt agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of sucrose and raffinose is doubtful.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1422, ATCC 17918, CBS 720.72, DSM 40506, NBRC 13419, JCM 4816, LMG 19346, NRRL B-12431, NRRL-ISP 5506, RIA 1380, VKM Ac-979.

Sequence accession no. (16S rRNA gene): AB184390.

384. **Streptomyces prasinus** Ettlinger, Corbaz and Hütter 1958a, 343[AL]

pra′si.nus. L. masc. adj. *prasinus* green.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Spirals are poorly developed and show only one to three turns; loops and hooks are of small diameter on short spore chains and therefore are not typical of well developed *Retinaculiaperti* spore chains. Mature spore chains are moderately short with 3–10, or sometimes more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Green color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown on yeast-malt agar and oatmeal agar, and grayed yellow-brown modified slightly by green on salts-starch agar and glycerol-asparagine agar). Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Variable reports on growth with L-arabinose and raffinose.

Type strain shows the highest sequence similarity to: *S. bambergiensis*, AB184869, 99.9%; *S. hirsutus*, AB184844, 99.1%; *S. cyanoalbus*, AB184882, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19800, CBS 552.68, BCRC 13681, DSM 40099, NBRC 12810, JCM 4192, JCM 4603, NRRL B-2712, NRRL-ISP 5099, RIA 1079, UNIQEM 186, VKM Ac-1725.

Sequence accession no. (16S rRNA gene): DQ026658.

385. **Streptomyces prunicolor** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 63[AL] ("*Actinomyces prunicolor*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 184)

pru.ni.co′lor. L. n. *prunum* plum; L. n. *color* color; N.L. *prunicolor* plum colored, referring to the color of the vegetative mycelium of the organism.

Spore chains in Section *Rectiflexibiles*. Straight to flexuous spore chains are generally long with 10–50, or sometimes more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Long aerial hyphae may become entangled into knots or nest-like bodies.

Color of colony: mature aerial mass color in the Red color series (5cb, grayish yellowish pink) on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; immature aerial mycelium may be white to yellow on these media and sporulation on oatmeal agar is usually inadequate for accurate spore mass color determination. Reverse side of colony is light brown to reddish brown on yeast-malt agar; grayish yellow, reddish gray, reddish purple, or dark reddish purple on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reports vary on the production of the reddish purple reverse pigment. Reverse mycelium pigment is not a pH indicator, or is changed only slightly with addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment, or only a trace of pale brown, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. Reports vary on utilization of sucrose.

Type strain shows the highest sequence similarity to: *S. resistomycificus*, AB184166, 99.1%; *S. galilaeus*, AB045878, 99%; *S. phaeoluteigriseus*, AJ391815, 99%; *S. novaecaesareae*, AB184357, 99%; *S. chartreusis*, AB184839, 99%; *S. bobili*, AB249925, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1413, ATCC 25487, CBS 915.69, DSM 40335, NBRC 13075, IMET 43129, INA 8805/64, JCM 4508, LMG 19311, NCIMB 9978, NRRL B-12281, NRRL-ISP 5335, PCM 2370, RIA 1267, VKM Ac-992.

Sequence accession no. (16S rRNA gene): DQ026659.

386. **Streptomyces psammoticus** Virgilio and Hengeller 1960, 167[AL]

psam.mo′ti.cus. Gr. n. *psammos* sand; N.L. masc. adj. *psammoticus* sandy.

Spore chains in Section *Rectiflexibiles* to *Retinaculiaperti* with 10 to 50 or more spores per chain on oatmeal agar and glycerol-asparagine agar. Spore chains may be flexuous or irregularly turned in various forms and coremia or sclerotia-like bodies may be formed. Yeast-malt agar and salts-starch agar are not suitable media for observation of spore chain morphology. Spore surface is smooth; spores are irregular in size and shape.

Color of colony: aerial mass color in the Green color series (1½ge, light grayish olive) on oatmeal agar and salts-starch agar, and sometimes in marginal areas on yeast-malt agar or glycerol-asparagine agar. According to one observer the aerial mass color is in the Yellow color series (color tab 1dc, pale yellow-green). Reverse side of colony with no distinctive pigments (nearly colorless to pale yellow or grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; orange-yellow to yellow-brown on yeast-malt agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or a trace of yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, sucrose, and D-fructose are utilized for growth. Utilization of L-arabinose is doubtful. No growth or only trace of growth with D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. avellaneus*, AB184413, 100%; *S. aureofaciens*, AY207608, 99.6%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.3%; *S. purpureus*, AJ781324, 99.3%; *S. aburaviensis*, AY999779, 99.1%; *S. xanthocidicus*, AY999858, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1465, ATCC 14125, ATCC 25488, CBS 175.61, CBS 299.65, CBS 916.69, BCRC 12241, DSM 40341, NBRC 13877, NBRC 13971, JCM 4434, NRRL B-3291, NRRL B-5753, NRRL-ISP 5341, PCM 2371, RIA 1268, RIA 832, VKM Ac-996.

Sequence accession no. (16S rRNA gene): AY999862.

387. **Streptomyces pseudoechinosporeus** (Konev, Tsyganov, Minbaev and Morogov 1967) Goodfellow, Williams and Alderson 1986a, 575[VP] (Effective publication: Goodfellow, Williams and Alderson 1986a, 52.) ("*Microechinospora grisea*" Konev, Tsyganov, Minbaev and Morogov 1967, 309; *Microellobosporia grisea* Pridham 1970, 17)

pseu.do.e.chi.no.spo′re.us. Gr. adj. *pseudes* false; Gr. n. *ekhinos* hedgehog, sea-urchin; Gr. n. *spora* seed; N.L. masc. adj. *pseudoechinosporeus* false spiny spored.

Forms extensively branched substrate and aerial mycelium. Single or chains of up to three spores are formed on both the substrate and aerial mycelium. Spores have smooth surfaces and are unequal in size (1.8–3.5 µm diameter). They were originally thought to be spiny but are now known to be heavily encrusted in needle-like crystals. The aerial spore mass is white to glaucous gray; the reverse color is pink to light violet pink. Does not form melanin pigments. Gelatin is degraded but cellulose is not. Does not reduce nitrate or produce hydrogen sulfide. L-Arabinose, D-fructose, D-galactose, D-glucose, inulin, D-lactose, maltose, mannitol, raffinose, L-rhamnose, starch, sucrose, and D-xylose are used as sole carbon sources but cellulose and sorbitol are not. Grow at 20, 26, and 37°C, but not at 50°C. The wall peptidoglycan contains LL-A_2pm as the major diamino acid.

Type strain shows the highest sequence similarity to: *S. cinnamoneus*, AB184850, 99.9%; *S. hiroshimensis*, AB184789, 99.5%; *S. caeruleus*, EF178675, 99.2%; *S. aureoversilis*, AB184855, 99.1%; *S. blastmyceticus*, AY999802, 99.1%; *S. lilacinus*, AB184819, 99%; *S. abikoensis*, AB184537, 99%.

Source: isolated from sand collected from the south-west part of the Kyzyl-Kum desert, USSR.

DNA G+C content (mol%): 69.0.

Type strain: ATCC 19618, DSM 43035, IFM 1243, NBRC 12518, IMET 43494, KCC A-0066, KCTC 9178, JCM 3066, NCIMB 9918, RIA 554, RIA 897, VKM Ac-1226.

Sequence accession no. (16S rRNA gene): AB184100.

Further comments: for the transfer of *Microellobosporia grisea* (Konev et al. 1967) Pridham 1970 in the genus *Streptomyces* Waksman and Henrici 1943 it is necessary to substitute a new specific epithet to produce *Streptomyces pseudoechinosporeus* because there is a senior homonym, *Streptomyces*

griseus (Krainsky 1914) Waksman and Henrici 1948, included on the Approved Lists of Bacterial Names [Rules 34a and 41a of the *Bacteriological Code* (1990 Revision)].

388. **Streptomyces pseudogriseolus** Okami and Umezawa *in* Okami, Utahara, Ōyagi, Nakamura, Umezawa, Yanagisawa and Tunematsu 1955, 128[AL]

pseu.do.gri.se.o′lus. Gr. adj. *pseudes* false; N.L. dim. adj. *griseolus* specific epithet; N.L. dim. adj. *pseudogriseolus* the false *griseolus* referring to resemblance to *Streptomyces griseolus*.

Spore chains in Section *Spirales*. Spore chains suggesting *Retinaculiaperti* morphology may also be common. Mature spore chains are moderately short, often with 3–10 spores per chain, but longer chains are formed on suitable media. This morphology is seen on yeast-malt agar and salts-starch agar, but aerial mycelium is poorly developed on oatmeal agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar and salts-starch agar; poor sporulation on oatmeal agar and glycerol-asparagine agar. The aerial mycelium is described as grayish buff in the original description by Okami and Umezawa (1955). Reverse side of colony with no distinctive pigments (colorless to grayish yellow or yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment, or only trace of yellow, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth with sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. gancidicus*, AB184660, 100%; *S. capillispiralis*, AB184577, 100%; *S. cellulosae*, DQ442495, 99.9%; *S. levis*, AB184670, 99.5%; *S. azureus*, EF178674, 99.5%; *S. lusitanus*, AB184424, 99.4%; *S. rubiginosus*, AY999810, 99.4%; *S. carpinensis*, AB184574, 99.4%; *S. albaduncus*, AY999757, 99.2%; *S. matensis*, AB184221, 99.2%; *S. griseoloalbus*, AB184275, 99.1%; *S. djakartensis*, AB184657, 99.1%; *S. tuirus*, AB184690, 99.1%; *S. caelestis*, X80824, 99.1%; *S. paradoxus*, AB184628, 99%; *S. afghaniensis*, AJ399483, 99%; *S. geysiriensis*, DQ442501, 99%; *S. viridiviolaceus*, AY999854, 99%; *S. africanus*, AY208912, 99%; *S. lavendulocolor*, DQ442516, 99%; *S. minutiscleroticus*, EF178696, 99%.

Type strain: ATCC 12770, ATCC 23949, CBS 933.68, BCRC 12132, DSM 40026, NBRC 12902, JCM 4071, JCM 4663, NCIMB 9411, NCIMB 9814, NRRL B-3288, NRRL-ISP 5026, RIA 1106, VKM Ac-1859.

Sequence accession no. (16S rRNA gene): DQ442541.

389. **Streptomyces pseudovenezuelae** (Kuchaeva, Krasil'nikov, Taptykova and Gesheva 1961) Pridham 1970, 24[AL] ("*Actinomyces pseudovenezuelae*" Kuchaeva, Krasil'nikov, Taptykova and Gesheva 1961, 114)

pseu.do.ve.ne.zu.e′la.e. Gr. adj. *pseudes* false; N.L. gen. n. *venezuelae* a specific epithet; N.L. gen. n. *pseudovenezuelae* the false venezuelae, referring to resemblance to *Streptomyces venezuelae.*

Spore chains in Section *Rectiflexibiles.* Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5dc, grayish yellowish pink) on yeast-malt agar, oatmeal agar, and salts-starch agar; Gray or White color series on glycerol-asparagine agar (Gray or White is also sometimes reported for yeast-malt agar, oatmeal agar, and salts-starch agar). Reverse side of colony with no distinctive pigments (light grayish yellow to orange yellow or light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Trace of grayish yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. resistomycificus*, AB184166, 99.5%; *S. novaecaesareae*, AB184357, 99.5%; *S. phaeoluteigriseus*, AJ391815, 99.4%; *S. canus*, AY999775, 99.4%; *S. galilaeus*, AB045878, 99.3%; *S. bobili*, AB249925, 99.2%; *S. ciscaucasicus*, AY508512, 99.2%; *S. flavovariabilis*, EF178691, 99.2%; *S. chartreusis*, AB184839, 99.1%; *S. cyaneus*, AF346475, 99.1%; *S. aureocirculatus*, AB184260, 99.1%; *S. humidus*, DQ442508, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 13875, DSM 41657, NBRC 3855, KCTC 9766, JCM 7545.

Sequence accession no. (16S rRNA gene): AB184806.

391. **Streptomyces puniceus** Patelski *in* Routien and Hofmann 1951, 387[AL]

pu.ni′ce.us. L. adj. *puniceus* reddish, purple.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar and glycerol-asparagine agar. One observer places this culture in the Gray series (tabs 2dc, yellowish gray and 3fe, light grayish brown) on these media. Reverse side of colony is violet on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed from violet to blue-violet or blue by addition of 0.05 M NaOH and from violet to pink or red with 0.05 M HCl.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. Traces of blue or violet pigment found in medium in yeast-malt agar and glycerol-asparagine agar after 14–21 d. Pigment, when present, is changed from blue or violet to red-violet by 0.05 M HCl.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on L-arabinose, iso-inositol, and rhamnose. Utilization of sucrose is doubtful and reports are variable for growth with raffinose.

Type strain shows the highest sequence similarity to: *S. phaeofaciens*, AB184360, 100%; *S. rishiriensis*, EF178691, 99.1%.

Type strain: ATCC 19801, CBS 308.55, CBS 553.68, BCRC 12097, DSM 40083, NBRC 12811, JCM 4406, NRRL B-2895, NRRL-ISP 5083, RIA 1080, UNIQEM 187, VKM Ac-579.

Sequence accession no. (16S rRNA gene): DQ442542.

392. **Streptomyces puniciscabiei** Park, Kim, Kwon, Wilson, Yu, Hur and Lim 2003, 2053[VP]

pu.ni.ci.sca′bi.ei. L. adj. *puniceus* purple or red; L. n. *scabies* roughness, scabbiness; N.L. gen. n. *puniciscabiei* of purple roughness, intended to mean purple or red, scab-causing bacteria.

Spores are pale orange, spiny, and borne in simple rectus flexuous spore chains. Melanin is produced on tyrosine agar, but not on peptone agar. L-Arabinose, D-fructose, D-glucose, D-mannitol, raffinose, rhamnose, sucrose, D-xylose, and iso-inositol are utilized for growth. Minimum pH for growth is 3.5. Sensitive to 10 and 100 μg/ml thallium acetate and 20 μg/ml streptomycin, but not to 5, 6, and 7% (w/v) NaCl, 0.5 μg/ml crystal violet, 0.1% (w/v) phenol, 10 IU/ml penicillin, or 25 or 100 μg/ml oleandomycin.

Type strain shows the highest sequence similarity to: *S. durhamensis*, AY999785, 99.1%. Type strain shows DNA–DNA similarity to: *S. scabies* ATCC 49173[T], 13%; *S. turgidiscabies* ATCC 700248[T], 13%; *S. acidiscabies* ATCC 49003[T], 11%; *S. bottropensis* DSM 40262[T], 12%; *S. neyagawaensis* DSM 40588[T], 6%; *S. diastatochromogenes* DSM 40449[T], 17%; *S. setonii* DSM 40395[T], 13%; *S. griseus* subsp. *griseus* DSM 40236[T], 16%; *S. sampsonii* DSM 40394[T], 42%; *S. eurythermus* DSM 40014[T], 14%; *S. tendae* DSM 40101[T], 15%; *S. coelicolor* DSM 40233[T], 8%; " *S. lividans*" DSM 40434, 29%; *S. ambofaciens* DSM 40053[T], 12%; *S. luridiscabiei* LMG 21390[T], 14%; *S. niveiscabiei* LMG 21392[T], 13%.

Source: isolated from raised corky lesions on potato cv. Daeji-ma and pathogenic on potato cv. Daeji-ma.

DNA G+C content (mol%): 68.3.

Type strain: S77, KACC 20253, LMG 21391.

Sequence accession no. (16S rRNA gene): AF361785.

393. **Streptomyces purpeofuscus** Yamaguchi and Saburi 1955, 207[AL]

pur.pe.o.fus′cus. L. adj. *purpureus* purple; L. adj. *fuscus* dark, tawny; N.L. masc. adj. *purpeofuscus* dark purple, referring to color of vegetative mycelium.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow to olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but dark brown to reddish brown substrate mycelium pigment may be produced. The original description (Yamaguchi and Saburi, 1955) describes purple to brown reverse mycelium color but notes that this coloration may be lost on repeated transfer.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, but only traces of brownish black color in tyrosine agar or tryptone-yeast broth. Traces of red, violet, or yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. Utilization of fructose is doubtful. No growth or only trace of growth with sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. indigoferus*, AB184214, 99.2%; *S. herbaricolor*, AB184801, 99.2%; *S. aburaviensis*, AY999779, 99.1%. Type strain shows the highest sequence similarity to following *Kitasatospora* species: *Kitasatospora azatica*, U93312, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23952, CBS 935.68, BCRC 12093, DSM 40283, NBRC 12905, JCM 4156, JCM 4665, NCIMB 9822, NRRL B-1817, NRRL-ISP 5283, RIA 1197.

Sequence accession no. (16S rRNA gene): AJ781364.

394. **Streptomyces purpurascens** Lindenbein 1952, 371[AL]

pur.pur.as′cens. L. part. adj. *purpurascens* making purple.

Spore chains in Section *Spirales*. Mature spore chains are generally long with 10–50 or often more than 50 spores per chain. This morphology is seen on oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but spiral spore chains may be absent on yeast-malt agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink) or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (aerial mycelium may be thin and white or absent on yeast-malt agar or on glycerol-asparagine agar). Reverse side of colony is grayish yellowish pink to reddish brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator changing from red or purple to blue with addition of 0.05 M NaOH and to red or orange with addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tryptone-yeast broth and may or may not develop after 4 d in tyrosine agar. Red to violet pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When present, this pigment is pH-sensitive showing the same color changes recorded for reverse mycelium pigments.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. indiaensis*, AB184553, 99.6%; *S. hawaiiensis*, AB184143, 99.5%; *S. bellus*, AB184849, 99.4%; *S. coerulescens*, AY999720, 99.4%; *S. arenae*, AB249977, 99.3%; *S. lomondensis*, AB184673, 99.3%; *S. massasporeus*, AB184152, 99.3%; *S. coeruleorubidus*, AY999719, 99.2%; *S. lusitanus*, AB184424, 99.2%; *S. luteogriseus*, AB184379, 99.1%; *S. iakyrus*, AB184877, 99.1%; *S. parvulus*, AB184326, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 25489, CBS 917.69, BCRC 11872, DSM 40310, NBRC 13077, JCM 4509, NRRL B-12230, NRRL-ISP 5310, PCM 2299, RIA 1269, VKM Ac-755.

Sequence accession no. (16S rRNA gene): AB045888.

395. **Streptomyces purpureus** (Matsumae and Hata 1968) Goodfellow, Williams and Alderson 1986a, 575[VP] (Effective publication: Goodfellow, Williams and Alderson 1986b, 65.) (*Kitasatoa purpurea* Matsumae and Hata *in* Matsumae, Ohtani, Takeshima and Hata 1968, 617.)

pur.pur′e.us. L. masc. adj. *purpureus* purple colored.

Forms extensively branched substrate and aerial mycelium. Spore chains in Section *Rectiflexibiles*. Spore surface is smooth. Hyphae have been reported to carry club-shaped sporangia enclosing chains of zoospores with a single polar flagellum. The aerial spore mass is either gray or red and a yellow-brown diffusible pigment is produced. Melanin pigments are formed. Adenine, esculin, allantoin, arbutin, casein, elastin, guanine, hypoxanthine, starch, testosterone, tyrosine, urea, and xanthine are degraded but pectin and xylan are not. Nitrate is reduced to nitrite and hydrogen sulfide is produced. L-Arabinose, cellobiose, D-fructose, D-glucose, glycerol, *myo*-inositol, maltose, D-mannose, melezitose, salicin, and trehalose are used as sole carbon sources but adonitol, dulcitol, inulin, D-lactose, mannitol, melibiose, raffinose, L-rhamnose, sucrose, xylitol, and D-xylose are not. Grows on L-arginine and potassium nitrate but not on DL-amino-n-butyric acid, L-cysteine, L-histidine, L-hydroxyproline, L-methionine, L-phenylalanine, L-serine, L-threonine, or L-valine as sole nitrogen source. Growth occurs at 37°C but not at 10 or 45°C. Tolerant to sodium chloride (4%, w/v) but not to phenol (0.1%, w/v) or sodium azide (0.01%, w/v). Resistant to rifampin but sensitive to sodium chloride at 7% (w/v). Some strains show antimicrobial activity against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Micrococcus luteus* NCIB 196, and *Streptomyces murinus* ISP 5091, but such activity is not shown against *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Pseudomonas fluorescens* NCIB 9046[T], or *Saccharomyces cerevisiae* CBS 1171[T]. The peptidoglycan contains LL-A_2pm as the major diamino acid and is of the A3γ type (Stackebrandt et al., 1981). Have a type II phospholipid pattern (*sensu* Lechevalier et al., 1977) and contain octahydrogenated menaquinones with nine isoprene units as the major isoprenolog. Produces the antibiotic chloramphenicol.

Type strain shows the highest sequence similarity to: *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.9%; *S. herbaricolor*, AB184801, 99.6%; *S. indigoferus*, AB184214, 99.6%; *S. aburaviensis*, AY999779, 99.5,%; *S. xanthocidicus*, AY999858, 99.5%; *S. psammoticus*, AY999862, 99.3%; *S. avellaneus*, AB184413, 99.2%. Type strain shows the highest sequence similarity to following *Kitasatospora* species: *Kitasatospora kifunensis*, AB022874, 99.2%.

Source: isolated from soil in Hawaii and Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 27787, BCRC 12101, DSM 43362, NBRC 13927, IMET 9041, JCM 3172, KCC A-0172, KCTC

9187, LMG 19368, NCIMB 11311, NRRL B-5403, VKM Ac-1298.

Sequence accession no. (16S rRNA gene): AJ781324.

Further comments: Goodfellow et al. (1986a) proposed that *Kitasatoa diplospora* Matsumae et al. 1968, *Kitasatoa kauaiensis* Matsumae et al. 1968, and *Kitasatoa nagasakiensis* Matsumae and Hata 1968 become later synonyms of *Kitasatoa purpurea* Matsumae and Hata 1968, and that the latter be transferred to the genus *Streptomyces* as *Streptomyces purpureus* (Matsumae and Hata 1968) Goodfellow et al. 1986b, comb. nov.

396. **Streptomyces purpurogeneiscleroticus** (Thirumalachar *in* Thirumalachar and Sukapure 1964) Pridham 1970, 43[AL] ("*Chainia purpurogena*" Thirumalachar *in* Thirumalachar and Sukapure 1964, 160)

pur.pur.o.ge.ni.scle.ro′ti.cus. L. adj. *purpureus* purple colored; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. n. *sclerotium* sclerotium; N.L. part. adj. *purpurogeneiscleroticus* sclerotium along with producing purple color.

Spore chains in Section *Spirales* on yeast-malt agar and salts-starch agar. Sporulation may be thin on these media and is generally absent on oatmeal agar and glycerol-asparagine agar. Mature spore chains generally contain 10 or more spores per chain. Spore surface is smooth. Sclerotia are produced on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 14 d.

Color of colony: aerial mass color in the White color series on yeast-malt agar and salts-starch agar; aerial mycelium is not produced on oatmeal agar or glycerol-asparagine agar. Reverse side of colony is grayish yellow on salts-starch agar; brown or reddish brown on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. One of three observers reports the reddish brown reverse mycelium pigment is changed from dark brown to light brown with the addition of 0.05 M HCl. The other observers report no change.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Reddish or yellowish pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. This pigment is pH-sensitive, changing from brown to reddish brown or red with the addition of 0.05 M NaOH and from brown to yellowish brown or yellow with the addition of 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. ochraceiscleroticus*, AB184094, 99.9%; S. *violens*, AJ621605, 99.7%; *S. monomycini*, DQ445790, 99.3%; *S. olivaceiscleroticus*, AJ621606, 99.1%; *S. sioyaensis*, DQ026654, 99.1%; *S. erumpens*, AJ621603, 99.1%; *S. niger*, AJ621607, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19348, CBS 409.66, CBS 659.72, BCRC 13317, CM 3103, CMI 112722, DSM 43156, HAMBI 1061, NBRC 13001, NBRC 13903, JCM 3080, JCM 4818, NCIMB 10981, NRRL B-2952, NRRL-ISP 5271, PCM 2306, RIA 1319, RIA 886.

Sequence accession no. (16S rRNA gene): AJ621604.

Further comments: Streptomyces purpurogeneiscleroticus Pridham 1970 and *Chainia purpurogena* Thirumalachar and Sukapure 1964 have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b (1) of the *Bacteriological Code* (1990 Revision)].

397. **Streptomyces racemochromogenes** Sugai 1956, 171[AL]

ra.ce.mo.chro.mo′ge.nes. L. n. *racemus* a raceme or cluster of berries; N.L. part. adj. *chromogenes* producing color; N.L. part. adj. *racemochromogenes* raceme, producing color (probably referring to morphology of spore chains and to chromogenicity).

Spore chains in Section *Retinaculiaperti* including many *Rectiflexibiles* spore chains, and some long chains with terminal hooks or primitive spirals of wide diameter. Mature spore chains are generally long with 10–50, or often more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5ec and 5cb, grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Areas of gray or white sporulation may also be seen. Reverse side of colony with no distinctive pigments on oatmeal agar, but yellow to yellow brown substrate mycelium color may be modified in some areas by blue pigment (dark olive green, grayish green or grayish blue) on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. The blue pigment is not always present. When present, it can be intensified from grayish green to reddish gray by 0.05 M HCl.

Color in medium: melanoid pigments are produced in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment other than a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, and sucrose are utilized for growth. Only traces of growth are found on D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. polychromogenes*, AB184292, 100%; *S. flavotricini*, AB184132, 99.7%; *S. katrae*, AB184409, 99.5%; *S. cinnamonensis*, AB184707, 99.1%; *S. tanashiensis*, AJ781362, 99.1%; *S. globosus*, AJ781330, 99.1%; *S. toxytricini*, DQ442548, 99.1%; *S. nashvillensis*, AB184286, 99.1%; *S. nojiriensis*, AJ781355, 99%; *S. sporoaveus*, AJ781370, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23954, CBS 937.68, BCRC 12318, DSM 40194, NBRC 12906, JCM 4407, NRRL B-5430, NRRL-ISP 5194, RIA 1147, VKM Ac-1206.

Sequence accession no. (16S rRNA gene): DQ026656.

398. **Streptomyces radiopugnans** Mao, Tang, Zhang, Wang, Wei, Huang, Liu, Shi and Goodfellow 2007, 2581[VP]

ra.di.o.pug′nans. L. n. *radius* a beam or ray; N.L. pref. *radio-* pertaining to radiation; L. part. adj. *pugnans* fighting or resisting; N.L. part. adj. *radiopugnans* radiation-resisting.

Radiation-resistant actinomycete that forms an extensively branched substrate mycelium which carries aerial

hyphae that differentiate into spiral chains of spores with rough to warty surfaces. Moderate to abundant, white to pale gray aerial spore mass is formed on modified Bennett's, Gause's synthetic medium no. 1, inorganic salts-starch, yeast extract-malt extract, and yeast-starch agars. Substrate mycelium is yellowish brown on modified Bennett's, Gause's synthetic medium no. 1, and yeast-starch agars, and light pinkish yellow on inorganic salts-starch and yeast extract-malt extract agars. Diffusible pigments are not formed on any of the media nor are melanin pigments formed on peptone-yeast extract iron or tyrosine agars. L-Arabinose, melezitose, and ribose are used as sole carbon sources for energy and growth, but not cellobiose, lactose, lactulose, melibiose, raffinose, or trehalose (all at 1%, w/v). Similarly, L-cysteine, L-glycine, D-glutamate, sodium azelate, sodium isobutyrate, and sodium malonate are used as sole carbon sources for energy and growth, but not D-glutamic acid, L-hydroxyproline, DL-isoleucine, L-leucine, methyl-D-glucopyranoside, methyl α-D-mannopyranoside, L-phenylalanine, sodium propionate, sodium pyruvate, sodium suberate, or spermidine (all at 0.1%, w/v).

The fatty acid profile consists of $C_{16:0}$ iso (34.5%), $C_{15:0}$ anteiso (15.4%), $C_{16:1}$ iso-H (14.2%), $C_{17:0}$ anteiso (9.1%), $C_{14:0}$ iso (5.6%), and $C_{17:1}$ anteiso ω9*c* (5.2%).

Type strain shows no sequence similarity over 99%.

Source: strain R97^{T} was isolated from a radiation-contaminated soil sample collected from Yinjiang Province, Northwestern China.

DNA G+C content (mol%): 72.7.

Type strain: R97, CGMCC 4.3519, DSM 41901.

Sequence accession no. (16S rRNA gene): DQ912930.

399. **Streptomyces rameus** Shibata 1959, 398^{AL}

ra′me.us. L. masc. adj. *rameus* pertaining to branches.

Produces streptomycin.

Type strain shows the highest sequence similarity to: *S. bangladeshensis*, AY750056, 99.8%; *S. glomeratus*, AB249917, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 21273, DSM 41685, NBRC 16196, JCM 5064, KCTC 9767.

Sequence accession no. (16S rRNA gene): AY999821.

Further comments: in a Request for an Opinion, Hatano (1999) proposed that the type strain of *Streptomyces rameus* Shibata 1959 is strain 43797, NBRC 3782, which was the originally designated type strain. The Judicial Commission supported this request and decided that strain 43797 [NBRC (previously IFO) 3782, ATCC 700861, JCM 11574] has to replace ATCC 21273 (DSM 41685, NBRC 16196, JCM 5064) as given in the Approved Lists.

400. **Streptomyces ramulosus** Ettlinger, Gäumann, Hütter, Keller-Schierlein, Kradolfer, Neipp, Prelog and Zähner 1958b, 217^{AL}

ra.mu.lo′sus. L. masc. adj. *ramulosus* much branched.

Spore chains in Section *Retiflexibiles*. Short dichotomous spore chains often occur in dense clumps of clusters. Short spore chains of 3–10 spores per chain. This morphology is seen on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar; poor sporulation on oatmeal agar. Reverse side of colony: substrate is colorless on oatmeal agar and grayed reddish brown to dark brown on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar (one observer, only, reports reverse color as changed from grayed red to grayed yellow by 0.05 M NaOH and from grayed red to grayed purplish color by 0.05 M HCl).

Color in medium: melanoid pigments probably not formed in peptone-yeast-iron agar and tyrosine agar (a light orange pigment is formed in peptone-yeast-iron agar). Red pigment found in medium in yeast-malt agar and glycerol-asparagine agar; red to violet pigment found in oatmeal agar and salts-starch agar. One observer, only, reports pigment changed to yellow by 0.05 M NaOH and to violet by 0.05 M HCl (two observers reported no change).

D-Glucose, D-mannitol, and raffinose are utilized for growth. Doubtful growth on D-fructose. No growth or only trace of growth on L-arabinose, sucrose, D-xylose, iso-inositol, and rhamnose.

Type strain shows the highest sequence similarity to: *S. hygroscopius* subsp. *glebosus*, AB184479, 99.3%; *S. libani* subsp. *rufus*, AJ781351, 99.3%; *S. caniferus*, AB184640, 99.3%; *S. catenulae*, AJ621613, 99.1%; *S. misakiensis*, AB217605, 99.1%; *S. platensis*, AB045882, 99.1%; *S. rimosus* subsp. *rimosus*, AB045883, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1434, ATCC 19802, CBS 554.68, BCRC 12343, DSM 40100, HAMBI 981, NBRC 12812, NBRC 15798, JCM 4193, JCM 4604, KCTC 9768, LMG 19354, NRRL B-2714, NRRL-ISP 5100, RIA 1081, UNIQEM 188, VKM Ac-1001.

Sequence accession no. (16S rRNA gene): DQ026662.

401. **Streptomyces rangoonensis** corrig. (Erikson 1935) Pridham, Hesseltine and Benedict 1958, 61^{AL} ["*Actinomyces rangoon*" (*sic*) Erikson 1935, 37; "*Nocardia rangoonensis*" (*sic*) Waksman and Henrici 1948, 911]

ran.goon.en′sis. N.L. masc. adj. *rangoonensis* of or belonging to Rangoon, Burma.

Spore chains in Section *Spirales*. Flexuous chains and irregular spirals are also common. Mature spore chains generally have 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to pale yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; yellowish brown to light olive brown on yeast-malt agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Utilization of L-arabinose is doubtful. Only traces of growth or no growth is found on iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. almquistii*, AB184258, 100%; *S. gibsonii*, AB184663, 100%; *S. albus* subsp. *albus*, AJ621602, 100%; *S. flocculus*, AB184272, 99.9%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25490, ATCC 6860, CBS 918.69, DSM 40452, HUT 6616, NBRC 13078, IMET 41357, JCM 4510, NRRL B-12378, NRRL B-16595, NRRL-ISP 5452, RIA 1270, VKM Ac-1899.

Sequence accession no. (16S rRNA gene): AB184295.

Further comments: the original spelling of the specific epithet, *rangoon* (*sic*), has been corrected by Trüper and De'Clari (1997).

In the opinion of Kilian (1998), the change of the well-established name *Streptomyces rangoon* may be a source of confusion. So, with reference to the first Principle of the *Bacteriological Code* (1990 Revision), Kilian (2001) requested that the original name *Streptomyces rangoon* be conserved. The Judicial Commission 2005 denied this request and no opinion will be issued upon this request.

402. **Streptomyces recifensis** (Gonçalves de Lima, Machado, Araujo, Falcão de Morais and Biermann 1955) Falcão de Morais, Gonçalves de Lima and Maia 1957, 249^{AL} ("*Nocardia recifei*" Gonçalves de Lima, Machado, Araujo, Falcão de Morais and Biermann 1955, 26)

re.cif.en'sis. N.L. masc. adj. *recifensis* of or belonging to Recife, Brazil, the source of the soil from which the organism was isolated.

Spore chains in Section *Retinaculiaperti*; spore chains representative of Section *Rectiflexibiles* are also present. Mature spore chains generally have 10–50 spores per chain. This morphology is found on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on oatmeal agar, salts-starch agar, and glycerol-asparagine agar, grayed yellow modified by dark grayish green on yeast-malt agar. Substrate pigment is not a pH indicator.

Color in medium: Melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only traces of growth on iso-inositol and rhamnose.

Type strain shows the highest sequence similarity to: *S. griseoluteus*, AY999751, 99.9%; *S. seoulensis*, AB249970, 99.8%.

Source: isolated from soil from Recife, Brazil.

DNA G+C content (mol%): not known.

Type strain: ATCC 19803, CBS 555.68, BCRC 12086, DSM 40115, NBRC 12813, JCM 4408, NRRL B-3811, NRRL-ISP 5115, RIA 1082, UNIQEM 189, VKM Ac-1890.

Sequence accession no. (16S rRNA gene): AB184165.

403. **Streptomyces rectiverticillatus** (Krasil'nikov and Yuan 1965) Witt and Stackebrandt 1991, 456^{VP} (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Actinomyces rectiverticillatus*" Krasil'nikov and Yuan 1965, 49; *Streptoverticillium rectiverticillatum* Locci, Baldacci and Petrolini Baldan 1969, 41)

rec.ti.ver.ti.cil.la'tus. L. adj. *rectus* straight; L. masc. n. *verticillus* whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *rectiverticillatus* straight and whorled.

Spore chains in Section *Verticillati*, umbellate monoverticillate. Monoverticillate morphology is also common. Mature spore chains are generally short with 3–10 or sometimes more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red or White color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony grayish yellowish pink to strong brown or reddish orange on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth, but may be weak in tyrosine agar. Yellow or red pigment is found in the medium in yeast-malt agar and oatmeal agar. Traces of yellow may also be present in salts-starch agar and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, iso-inositol, and D-fructose are utilized for growth. Utilization of sucrose and raffinose is doubtful. No growth or only trace of growth with L-arabinose, D-xylose, D-mannitol, or rhamnose.

For sequence similarity, see type strain of *Streptomyces hiroshimensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19845, ATCC 25491, CBS 951.69, BCRC 13306, CECT 3268, DSM 40436, NBRC 13079, INMI 380, JCM 4511, NRRL B-12369, NRRL-ISP 5436, RIA 1271, VKM Ac-1503.

Sequence accession no. (16S rRNA gene): AB184296.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces rectiverticillatus* is proposed as a *nomen revictum* (basonym: "*Streptomyces rectiverticillatus*" Krasil'nikov and Yuan (1965).

According to Hatano et al. (2003), *Streptomyces rectiverticillatus* (Krasil'nikov and Yuan 1965) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

404. **Streptomyces rectiviolaceus** (*ex* Artamonova *in* Krasil'nikov 1965) Sveshnikova 1986, 575^{VP} (Effective

publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces rectiviolaceus*" Artamonova *in* Krasil'nikov 1965, 234; *Streptomyces rectivioleceus* Pridham 1970, 25)

rec.ti.vio.la'ce.us. L. adj. *rectus* straight; L. adj. *violaceus* violet colored; N.L. masc. adj. *rectiviolaceus* straight, violet colored.

Spore chains are straight or flexuous (*Rectiflexibiles*). Spore surface is smooth. Forms violet or red-colored vegetative mycelium on some media. On mineral agar 1: aerial mycelium is white to light pink, poor; substrate mycelium is violet; diffusible pigment is poor, light violet or not extant. Pigment is able to act as an indicator: alkaline reaction, blue; acidic reaction, red. On glycerol-nitrate agar: aerial mycelium is white, good developed; substrate mycelium is reddish violet; no diffusible pigment. On starch-ammonia agar: aerial mycelium is white, poor; substrate mycelium is colorless to light violet; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is white, good developed; substrate mycelium is pale violet; no diffusible pigment. On glucose-nitrate agar SP-1: aerial mycelium is whitish, poor; substrate mycelium violet; no diffusible pigment. On oatmeal agar: aerial mycelium is white, poor; substrate mycelium is red-violet; no diffusible pigment. On organic agar 2: no aerial mycelium; substrate mycelium is pale violet; no diffusible pigment. Melanoid pigments are not formed. Grows on glucose, arabinose, xylose, rhamnose, sucrose, raffinose, mannitol and inositol. Exhibits anti-bacterial and anti-fungal activity.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 43690, DSM 41459, INMI 563, JCM 9092, NBRC 100765, NRRL B-16374, VKM Ac-282.

Sequence accession no. (16S rRNA gene): DQ026660.

405. **Streptomyces regensis** Gupta, Sobti and Chopra 1963, 15[AL]

reg.en'sis. N.L. masc. adj. *regensis* of or belonging to reg (unknown derivation, possibly referring to a place in India).

Spore chains in Section *Spirales* or *Rectiflexibiles*. Spirals are poorly developed, usually with only one or two turns or with hooks and loops of small diameter on short lateral spore chains. Flexuous or straight chains are also common. Aerial hyphae may be long, but spore chains are often moderately short with 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth or irregularly folded.

Color of colony: aerial mass color in the Gray or Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Representative color tabs from the Gray color series are 2dc, yellowish green; 2ge, light olive brown; and 3fe, light brownish gray. Representative color chips from the Yellow color series are 1½ec – 1cb, pale yellow green, and 1ba – 2ba, pale yellow. Reverse side of colony is moderate to strong or dark yellow, greenish yellow, or olive on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Strong yellow or strong brown on yeast-malt agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. capoamus*, AB045877, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27461, CBS 749.72, BCRC 11890, DSM 40551, NBRC 13448, JCM 4820, NRRL B-11479, NRRL-ISP 5551, RIA 1409, VKM Ac-1289.

Sequence accession no. (16S rRNA gene): DQ026649.

406. **Streptomyces resistomycificus** Lindenbein 1952, 376[AL]

re.sis.to.my.ci'fi.cus. L. v. *restisto* to resist; Gr. n. *mukês* fungus; L. masc. suff. *-ficus* (from L. v. *facio* to make) making, producing; N.L. masc. adj. *resistomycificus* making resistant to a fungus; producing resistomycin.

Spore chains in Section *Spirales*, but with many spore chains representative of Section *Retinaculiaperti* (especially when sporophores are immature). Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony dark reddish brown on yeast-malt agar; grayed brown to reddish brown on oatmeal agar and glycerol-asparagine agar; and grayed yellow to faint pinkish yellow on salts-starch agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast extract broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth.

Type strain shows the highest sequence similarity to: *S. pseudovenezuelae*, AB184233, 99.5%; *S. galilaeus*, AB045878, 99.5%; *S. chartreusis*, AB184839, 99.5%; *S. bobili*, AB249925, 99.5%; *S. phaeoluteigriseus*, AJ391815, 99.4%; *S. novaecaesareae*, AB184357, 99.3%; *S. canus*, AY999775, 99.3%; *S. aureocirculatus*, AB184260, 99.1%; *S. prunicolor*, DQ026659, 99.1%; *S. ciscaucasicus*, AY508512, 99.1%; *S. alboniger*, AY845349, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19804, CBS 556.68, BCRC 13755, DSM 40133, NBRC 12814, JCM 4409, NCIMB 9843, NRRL

2290, NRRL-ISP 5133, PCM 2296, RIA 1083, UNIQEM 190, VKM Ac-1895.

Sequence accession no. (16S rRNA gene): AB184166.

407. **Streptomyces reticuliscabiei** Bouchek-Mechiche, Gardan, Normand and Jouan 2000, 98[VP]

re.ti.cu.li.sca'bi.ei. L. n. *reticulum* reticulum; L. n. *scabies* mange; N.L. gen. n. *reticuliscabiei* referring to the reticulum aspect of the symptoms of the disease.

Spores are light gray and borne in mature flexuous chains. Melanin is not produced on tyrosine agar. Fructose, D-glucose, D-mannitol, inositol, raffinose, rhamnose, sucrose, and D-xylose are used as carbon sources. Utilizes α-D(+)melibiose, mucate, D-saccharate, D(+)trehalose, and 5-keto-D-gluconate. Does not grow in the presence of 0.5 μg/ml crystal violet, 20 μg/ml streptomycin, 100 μg/ml oleandomycin, or 5% (w/v) NaCl. Strains are not susceptible to 10 IU/ml penicillin G and some (about 60%) of the strains are not susceptible to 25 μg/ml oleandomycin. Does not assimilate *trans*-aconitate or ONPG. Most (about 80%) of the strains utilize DL-lactate and turanose. Some strains use betaine.

Type strain shows the highest sequence similarity to: *S. turgidiscabies*, AB026221, 99.1%. Type strain shows DNA–DNA similarity to: *S. europaeiscabiei* DSM 41802[T], 47%; *S. stelliscabiei* DSM 41803[T], 24%.

Source: isolated from netted scab lesions on potato cv. Bintje and have been confirmed to be pathogenic only on potato cv. Bintje.

DNA G+C content (mol%): 69.8.

Type strain: CFBP 4531, CIP 107061, DSM 41804, ICMP 13716, NCPPB 4041.

Sequence accession no. (16S rRNA gene): AJ007428.

Further comments: a numerical analysis of phenotypic characteristics showed that *Streptomyces reticuliscabiei* Bouchek-Mechiche et al. 2000 and *Streptomyces turgidiscabies* Miyajima et al. 1998 belong to the same cluster and share almost all morphological and biochemical traits that are important in the identification of *Streptomyces* species. DNA–DNA hybridization and phylogenetic comparisons of 16S rRNA gene sequences confirm that the two species are genomically closely related. In contrast, pathological data showed that *Streptomyces turgidiscabies* and *Streptomyces reticuliscabiei* cause two distinct diseases. For the pathologist, the fusion of *Streptomyces reticuliscabiei* and *Streptomyces turgidiscabies* under a single species denomination would cause confusion of separate diseases and create a discrepancy between taxonomists and pathologists. Therefore, Bouchek-Mechiche et al. think that the two groups should continue to carry their current denominations, i.e. *Streptomyces reticuliscabiei* Bouchek-Mechiche et al. 2000 for the strains inducing netted scab and *Streptomyces turgidiscabies* Miyajima et al. 1998 for those causing common scab.

408. **Streptomyces rhizosphaericus** corrig. Sembiring, Ward and Goodfellow 2001, 1619[VP] (Effective publication: Sembiring, Ward and Goodfellow 2000, 362.)

rhi.zo.spha.e'ri.cus. Gr. n. *rhiza* root; L. adj. *sphaericus* of or belonging to a ball, spherical; N.L. masc. adj. *rhizosphaericus* belonging to the sphere of the root.

Spore chains are *Spirales*; spore surface is rugose. On oatmeal agar, the spore mass is gray, the substrate mycelium is grayish-yellow, and the diffusible pigment is yellow. Melanin pigments are not produced. Degrades adenine and pectin and grows at 10°C.

Type strain shows the highest sequence similarity to: *S. asiaticus*, AB249947, 100%; *S. cangkringensis*, AJ391831, 99.8%; *S. griseinger*, AJ391818, 99.8%; *S. indonesiensis*, DQ334783, 99.7%; *S. antimycoticus*, AB184185, 99.1%; *S. sporoclivatus*, AB249934, 99.1%; *S. rutgersensis* subsp. *castelarensis*, AY508511, 99.1%; *S. geldanamycininus*, DQ334781, 99%. Type strain shows DNA–DNA similarity to: *S. albiflaviniger* NRRL B-1356[T], 98.1%; *S. geldanamycinus* NRRL 3602[T], 98.7%; *S. griseiniger* NRRL B1865[T], 99.2%; *S. asiaticus* DSM 41761[T], 98.6%; *S. indonesiensis* DSM 41759[T], 98.3%; *S. javensis* DSM 41764[T], 98.3%; *S. yogyakartensis* DSM 41766[T], 97.9%; *S. cangkringensis* DSM 41769[T], 99.0%.

Source: isolated from the rhizosphere of the tropical legume, *Paraserianthes falcataria*.

DNA G+C content (mol%): not known.

Type strain: A10P1, DSM 41760, JCM 11447, NBRC 100778, NCIMB 13674.

Sequence accession no. (16S rRNA gene): AB249941.

Further comments: the original spelling of the specific epithet, *rhizosphaerius* (*sic*), has been corrected on validation according to Rule 61 of the *Bacteriological Code* (1990 Revision).

409a. **Streptomyces rimosus subsp. rimosus** Sobin, Finlay and Kane *in* Waksman and Lechevalier 1953, 47[AL]

ri.mo'sus. L. masc. adj. *rimosus* full of fissures.

Spore chains in Section *Spirales*, but many imperfect spirals, hooks, and loops suggesting *Retinaculiaperti* morphology are also present. Mature spore chains are short to moderately long with 3–10, or often more than 10, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, and carbon utilization medium plus D-glucose. Spore surface is smooth.

Color of colony: aerial mass color in the Red or White color series on yeast-malt agar and in the Yellow or White color series on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Representative color tabs are 3ca (pale orange yellow), 5cb (grayish yellowish pink), and 2ca (pale yellow) from the Red color-wheel; 2db and 2ba (pale yellow) from the Yellow color-wheel; and a (white) from the White color-wheel. Reverse side of colony is grayish yellow on oatmeal agar and salts-starch agar; grayish yellow modified slightly by red (moderate to dark orange yellow) on yeast-malt agar and glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. A trace of yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Utilization of

D-xylose is doubtful. No growth or only trace of growth with sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. erumpens*, AJ621603, 99.7%; *S. sclerotialus*, AJ621608, 99.4%; *S. niger*, AJ621607, 99.3%; *S. olivaceiscleroticus*, AJ621606, 99.3%; *S. monomycini*, DQ445790, 99.1%; *S. ramulosus*, DQ026662, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Sequence accession no. (16S rRNA gene): AB184237.

412. **Streptomyces roseiscleroticus** (Thirumalachar *in* Rautenshtein 1960) Pridham 1970, 42[AL] (*Chainia poonensis* Thirumalachar *in* Rautenshtein 1960, 45)

ro.se.i.scle′ro.ti.cus. L. adj. *roseus* rosy; N.L. n. *sclerotium* a sclerotium; N.L. masc. adj. *roseiscleroticus* rosy, belonging to sclerotium.

Spore chains in Section *Spirales*. Mature spore chains are short to long, sometimes with more then 50 spores per chain. This morphology is sometimes seen on yeast-malt

agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, and or Gause's medium no. 1. Sporulating aerial mycelium is often absent on various media. Spore surface is smooth. Special morphological characteristics: sclerotia are produced on yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, and Gause's medium no. 1 in 7–14 d.

Color of colony: aerial mass color in the White color series when adequate aerial mycelium is produced on yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, or Gause's medium no. 1. Reports vary on the media supporting good growth of aerial mycelium. Reverse side of colony is yellow to yellow brown is modified by red to strong (reddish) brown on yeast-malt agar and to reddish orange or deep orange on oatmeal agar. Reverse mycelium on salts-starch agar and glycerol-asparagine agar may be colorless, light yellow, orange, or strong brown. No change is reported in reverse mycelium color after the addition of 0.05 M NaOH or HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of brown is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of sucrose, iso-inositol, and raffinose is doubtful.

Type strain shows the highest sequence similarity to: *S. ruber*, AB184604, 100%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 17755, CBS 226.65, CBS 664.72, BCRC 12541, CMI 112788, DSM 40303, NBRC 13002, NBRC 13363, IMET 43586, JCM 3104, JCM 4823, NCIMB 11013, NRRL B-3348, NRRL-ISP 5303, RIA 1324, RIA 887, VKM Ac-1718.

Sequence accession no. (16S rRNA gene): AB184251.

Further comments: Streptomyces roseiscleroticus Pridham 1970 and *Chainia rosea* Thirumalachar et al. 1966 have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b (1) of the *Bacteriological Code* (1990 Revision)].

413. **Streptomyces roseodiastaticus** (Duché 1934) Waksman *in* Waksman and Lechevalier 1953, 27[AL] ["*Actinomyces roseodiastaticus*" Duché 1934, 329; *Streptomyces roseodiastaticus* (Wollenweber 1920) Waksman 1961]

ro.se.o.di.a.sta′ti.cus. L. adj. *roseus* rosy; N.L. adj. *diastaticus* diastatic, starch, digesting; N.L. masc. adj. *roseodiastaticus* rosy, diastatic.

Excellent growth on Czapek's solution agar. Inhibited by streptomycin.

For sequence similarity, see type strain of *Streptomyces tricolor*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: CBS 102.34, DSM 41703, NBRC 15457, JCM 4295, JCM 13861, NRRL B-1906.

Sequence accession no. (16S rRNA gene): AB184683.

Further comments: according to Lanoot et al. (2004), *Streptomyces roseodiastaticus* (Duché 1934) Waksman 1953 is a later heterotypic synonym of *Streptomyces tricolor* (Wollenweber 1920) Waksman 1961.

414. **Streptomyces roseoflavus** Arai 1951, 218[AL] [*Streptomyces fradiae* (Waksman and Curtis 1916, 125) Waksman and Henrici 1948, 954]

ro.se.o.fla′vus. L. adj. *roseus* rosy; L. adj. *flavus* yellow; N.L. masc. adj. *roseoflavus* rose-yellow.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Flexuous spore chains are common; *Retinaculiaperti* and *Spirales* spore chains may not be seen on some media. Mature spore chains of more than 50 spores per chain may be seen if good sporulation occurs, but sporulation is often poor on yeast-malt agar, oatmeal agar, and salts-starch agar, and especially on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red or Yellow color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Yellow color series on oatmeal agar. Representative color tabs from the Red color series are 3ca, pale orange yellow; 4ec, grayish yellowish pink; and 5ca, light yellowish pink. Representative chips from the Yellow color series are 1 or 2ba, pale yellow; and 1½ec, pale yellowish green (yellow colors may represent poor sporulation). Reverse side of colony is moderate to deep orange on yeast-malt agar; grayish yellow to orange yellow or yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, or glycerol-asparagine agar; a trace of yellow to orange pigment may or may not be present in salts-starch agar.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. Utilization of fructose is doubtful. No growth or only traces of growth with iso-inositol, D-mannitol, rhamnose, sucrose, or raffinose.

For sequence similarity, see type strain of *Streptomyces fradiae*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 13167, CBS 740.72, DSM 40536, NBRC 13439, JCM 4824, NRRL B-1563, NRRL B-2789, NRRL-ISP 5536, RIA 1400, VKM Ac-1907.

Sequence accession no. (16S rRNA gene): no sequence available.

Further comments: according to Lanoot et al. (2004), *Streptomyces roseoflavus* Arai 1951 is a later heterotypic synonym of *Streptomyces fradiae* (Waksman and Curtis 1916) Waksman and Henrici 1948.

415. **Streptomyces roseofulvus** (Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 61[AL] ("*Actinomyces roseofulvus*" Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 55)

ro.se.o.ful′vus. L. adj. *roseus* rosy: L. adj. *fulvus* deep yellow; N.L. masc. adj. *roseofulvus* rosy, deep yellow, referring to color of aerial mycelium and vegetative mycelium, respectively.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long and straight, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, and salts-starch agar; poor sporulation on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar in 21 d. Younger cultures or cultures on media giving poor sporulation may show white aerial mycelium. Reverse side of colony is colorless or pale grayed yellow to pale pinkish yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed from colorless or pale yellow to pale pink by addition of 0.05 M NaOH, or from pinkish yellow to pale yellow with 0.05 M HCl.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast extract broth. Traces of pale grayish yellow or pale brownish gray pigment may be found in yeast-malt agar, oatmeal agar, and salts-starch agar. This faint pigment may be pH-sensitive (one observer only); the change is from pale yellow to pale pink by 0.05 M NaOH.

D-Glucose, L-arabinose, sucrose, D-xylose, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only trace of growth on iso-inositol and D-mannitol.

Type strain shows the highest sequence similarity to: *S. laurentii*, AJ781342, 99.2%; *S. roseolus*, AB184168, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19805, ATCC 19921, CBS 557.68, BCRC 12051, DSM 40172, NBRC 13194, NBRC 15816, NBRC 15817, INA 14535, JCM 4334, JCM 4605, NRRL B-2729, NRRL-ISP 5172, RIA 1084, UNIQEM 191, VKM Ac-1080.

Sequence accession no. (16S rRNA gene): AB184327.

416. **Streptomyces roseolilacinus** (Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 68[AL] ("*Actinomyces roseolilacinus*" Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 35)

ro.se.o.li.la.ci′nus. L. adj. *roseus* rosy; N.L. adj. *lilacinus* lilac colored; N.L. masc. adj. *roseolilacinus* rose, lilac colored, referring to color of the aerial mycelium of the organism.

Spore chains in Section *Retinaculiaperti* to *Spirales*. Spirals are prominent on salts-starch agar, but spore chains representative of Section *Retinaculiaperti* are more common on yeast-malt agar and oatmeal agar; poor sporulation on glycerol-asparagine agar. Mature spore chains generally have 10–50 spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator (or shows only slight change with 0.05 M HCl or NaOH on salts-starch agar and glycerol-asparagine agar).

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. Pigments not formed in medium or found only as traces of pale yellowish or brownish gray, in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and L-arabinose are utilized for growth. No growth or only trace of growth on sucrose, D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose. Doubtful growth with D-fructose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19806, ATCC 19922, CBS 558.68, BCRC 12329, DSM 40173, NBRC 12815, INA 14250, JCM 4335, JCM 4606, NRRL B-2699, NRRL-ISP 5173, RIA 1085, UNIQEM 192, VKM Ac-1276.

Sequence accession no. (16S rRNA gene): AB184167.

417. **Streptomyces roseolus** (Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 61[AL] ("*Actinomyces roseolus*" Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 37)

ro.se.o′lus. N.L. dim. masc. adj. *roseolus* somewhat rosy, referring to the color of the aerial mycelium.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long with 10–50 spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar and salts-starch agar, and in the Red or Yellow series on oatmeal agar. Sporulation may be poor on glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, D-mannitol, and raffinose. Variable reports of slight growth with D-fructose.

Type strain shows the highest sequence similarity to: *S. filamentosus*, AB184130, 99.4%; *S. roseofulvus*, AB184327, 99.2%; *S. tanashiensis*, AJ781362, 99.1%; *S. nashvillensis*, AB184286, 99%.

ro.se.o.spo′rus. L. adj. *roseus* rosy; N.L. n. *spora* a spore; N.L. masc. adj. *roseosporus* rosy-spored.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar (White, Yellow, or Red color series on glycerol-asparagine agar). Reverse side of colony with no distinctive pigments (grayish yellow to yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, and rhamnose are utilized for growth. Utilization of D-fructose is doubtful. No growth or only trace of growth with sucrose, iso-inositol, D-mannitol, and raffinose.

For sequence similarity, see type strain of *Streptomyces filamentosus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23958, CBS 941.68, BCRC 13771, DSM 40122, NBRC 12910, JCM 4412, KCTC 9568, NCIMB 13008, NRRL B-5411, NRRL-ISP 5122, RIA 1125.

Sequence accession no. (16S rRNA gene): AB184238.

Further comments: according to Lanoot et al. (2004), *Streptomyces roseosporus* Falcão de Morais and Dália Maia 1961 is a later heterotypic synonym of *Streptomyces filamentosus* Okami and Umezawa 1953.

419. **Streptomyces roseoverticillatus** (Shinobu 1956) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ("*Streptomyces roseoverticillatus*" Shinobu 1956; "*Verticillomyces roseoverticillatus*" Shinobu 1965; *Streptoverticillium roseoverticillatum* Farina and Locci 1966, 49)

ro.se.o.vert.i.cil.la′tus. L. adj. *roseus* rosy; L. masc. n. *verticillus* whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *roseoverticillatus* rosy whorled.

Spore chains in Umbellate Monoverticillate (=*Streptomyces* Section Verticillati, biverticillate). Mature spore chains are short, generally 3–10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow is modified by red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Only slight changes, if any, occur when pH is changed by addition of 0.05 NaOH or HCl.

Color in medium: melanoid pigments formed on peptone-yeast-iron agar and tryptone-yeast extract broth. Traces of yellow, orange, or red pigment may be found in yeast-malt agar and oatmeal agar. This pigment, when present, is not affected by pH or is changed slightly from orange in the presence of 0.05 M NaOH to pink in presence of 0.05 M HCl.

D-Glucose is utilized for growth. No growth or only trace of growth on L-arabinose, D-xylose, D-mannitol, rhamnose, and raffinose. Variable reports of doubtful growth to no growth with sucrose, iso-inositol, and D-fructose.

For sequence similarity, see type strain of *Streptomyces hiroshimensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19807, CBS 560.68, CECT 3269, DSM 40039, NBRC 12817, NBRC 3844, JCM 4103, JCM 4607, NRRL B-1993, NRRL-ISP 5039, PCM 2248, RIA 1087, RIA 552, UNIQEM 194, VKM Ac-880.

Sequence accession no. (16S rRNA gene): AB184169.

Further comments: Streptomyces roseoverticillatus (Shinobu 1956) Witt and Stackebrandt 1991 is an earlier synonym of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991, an earlier synonym of *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991, and an earlier synonym of *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991.

Labeda (1996) proposes *Streptomyces biverticillatus* (Preobrazhenskaya and Ryabova 1957) Witt and Stackebrandt 1991, *Streptomyces fervens* (DeBoer et al. 1959–1960) Witt and Stackebrandt 1991, and *Streptomyces roseoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 as later synonyms of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991. This proposal is in violation of Rule 24b(1) of the *Bacteriological Code* (1990 Revision) because the senior epithet is *roseoverticillatus*. *Streptomyces baldaccii*, *Streptomyces biverticillatus*, and *Streptomyces fervens* are therefore to be regarded as later synonyms of *Streptomyces roseoverticillatus*.

According to Hatano et al. (2003), *Streptomyces roseoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

420. **Streptomyces roseoviolaceus** (Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 68[AL] ("*Actinomyces roseoviolaceus*" Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 67)

ro.se.o.vi.o.la′ce.us. L. adj. *roseus* rosy; L. adj. *violaceus* violet colored; N.L. adj. *roseoviolaceus* rosy, violet colored, referring to color of aerial mycelium, vegetative mycelium, and diffusible pigment.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10 to 50 or more spores per chain.

This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red color series on oatmeal agar and salts-starch agar; Red or Violet color series on yeast-malt agar and glycerol-asparagine agar. The most representative color-tabs in the Red color series are 5cb or 5ec, grayish yellowish pink and the most representative tab in the Violet color series is 11ca, very pale purple. Reverse side of colony is purplish pink or purplish red on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator changing from red or pink to violet or blue-violet with addition of 0.05 M NaOH and violet to red or pinkish orange with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Red to violet pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive, showing the same changes noted for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. janthinus*, AB184851, 100%; *S. violaceus*, AB184315, 100%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 100%; *S. luteogriseus*, AB184379, 99.5%; *S. lomondensis*, AB184673, 99.3%; *S. hawaiiensis*, AB184143, 99.2%; *S. flavoviridis*, AB184842, 99.2%; *S. pilosus*, AB184161, 99.2%; *S. arenae*, AB249977, 99.2%; *S. africanus*, AY208912, 99.2%; *S. tuirus*, AB184690, 99.2%; *S. bellus*, AB184849, 99%; *S. mutabilis*, EF178679, 99%; *S. massasporeus*, AB184152, 99%; *S. afghaniensis*, AJ399483, 99%; *S. levis*, AB184670, 99%; *S. coerulescens*, AY999720, 99%; *S. parvulus*, AB184326, 99%; *S. coeruleorubidus*, AY999719, 99%.

Sequence accession no. (16S rRNA gene): AB184239.

422. **Streptomyces ruber** (Shirling and Gottlieb 1972) Goodfellow, Williams and Alderson 1986a, 575[AL] (Effective publication: Goodfellow, Willams and Alderson 1986d, 58.) (*Chainia rubra* Shirling and Gottlieb 1972, 347.)

ru′ber. L. masc. adj. *ruber* red.

Forms extensively branched substrate and aerial mycelium. Spiral spore chains containing 10 to over 50 spores are borne on the aerial mycelium. Spore surface is smooth or bears very short spines. Aerial spore mass is white or red and the substrate mycelium red. Sclerotia are formed in 14–21 d on agar medium. Melanin pigments are not produced. Xanthine is degraded but urea is not. Nitrate reductase is not formed. L-Arabinose, D-fructose, D-glucose, D-mannitol, rhamnose, and D-xylose are used as sole carbon sources, but raffinose is not utilized. Acid is formed from D-lactose, D-mannitol, melibiose, methyl α-D-glucoside, L-rhamnose, sucrose, and D-xylose but not from adonitol, dulcitol, *meso*-erythritol, *myo*-inositol, raffinose, or D-sorbitol. Grows at 42°C but not at 10°C. The organism contains major amounts of hexa- and octa-hydrogenated menaquinones with nine isoprene units (Collins et al., 1984).

Type strain shows the highest sequence similarity to: *S. roseiscleroticus*, AB184251, 100%; *S. poonensis*, DQ445792, 99.1%; *S. spiralis*, EF178683, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 17754, CBS 228.65, BCRC 12358, CMI 112789, DSM 40304, NBRC 14600, JCM 3131, KCC A-0131, NCIB (now NCIMB) 10983, NRRL B-5315, NRRL-ISP 5304.

Sequence accession no. (16S rRNA gene): AB184604.

423. **Streptomyces rubidus** Xu, Wang, Cui, Huang, Liu, Zheng and Goodfellow 2006, 1113[VP]

ru′bi.dus. L. masc. adj. *rubidus* dark red.

Neutrotolerant, acidophilic streptomycete that forms branched substrate and aerial hyphae. Smooth-surfaced

spores are borne in flexuous spore chains. Mahogany-colored substrate mycelium, sparse aerial hyphae and diffusible pigments are formed on oatmeal agar and yeast extract-malt extract agar. Melanin pigments are not produced on tyrosine agar or peptone-yeast extract-iron agar. Starch and Tween 80 are degraded, but adenine, guanine, and xanthine are not. Cellobiose, D-galactose, D-glucose, D-lactose, D-mannitol, D-salicin (each at 1%, w/v), L-arginine, and sodium citrate (0.1%, w/v) are used as sole carbon sources for energy and growth, but adonitol, inulin, D-sorbitol (each at 1%, w/v), adipic acid, L-alanine, DL-aminobutyric acid, α-L-aspartic acid, L-cysteine, L-phenylalanine, sodium acetate, sodium oxalate, and L-valine (each at 0.1%, w/v) are not. L-Alanine is used as a sole carbon and nitrogen source, but L-arginine, α-L-aspartic acid, L-glutamic acid, L-isoleucine, and L-phenylalanine (each at 0.1%, w/v) are not. Growth occurs at temperatures between 20 and 37°C, but not at 15°C, and at pH values from 4.5 to7.0, but not at pH 3.5. Does not grow in the presence of 5% (w/v) NaCl. Sensitive to filter-paper discs soaked in the following (μg/ml unless indicated): azithromycin (30), azetreonam (30), carbenicillin (10), cephalothin (30), ciprofloxacin (5), doxycycline hydrochloride (30), erythromycin (15), josamycin (15), kanamycin sulfate (30), minocycline hydrochloride (30), neomycin sulfate (30), streptomycin sulfate (10), tetracycline hydrochloride (30), and tobramycin sulfate (10), but resistant to filter-paper discs soaked in acetylspiramycin (15), amoxycillin (10), ampicillin (10),ofloxacin (5), penicillin G (10 IU/ml), rifampin (5), and sulfamethoxazole (25). Chemotaxonomic properties are typical of the genus *Streptomyces*.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. yeochonensis* NRRL B-24245^T, 43.0%; *S. guanduensis* JCM 13274^T, 21.4%; *S. paucisporeus* JCM 13276^T, 19.9%; *S. yanglinensis* JCM 13275^T, 23.8%.

Source: the type strain was isolated from a pine-forest Yanglin, Yunnan Province, People's Republic of China.

DNA G+C content (mol%): 70.6.

Type strain: 13c15, CGMCC 4.2026, JCM 13277.

Sequence accession no. (16S rRNA gene): AY876941.

424. **Streptomyces rubiginosohelvolus** (Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 59^{AL} ("*Actinomyces rubiginosohelvolus*" Kudrina *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 89)

ru.bi.gi.no.so.hel′vo.lus. L. masc. adj. *rubiginosus* rusty; L. adj. *helvolus* pale yellow, yellowish; N.L. masc. adj. *rubiginosohelvolus* rusty, yellowish.

Spore chains in Section *Rectiflexibiles*. Aerial mycelium is sometimes poorly developed on ISP media. Mature spore chains, when formed, contain 10 to 50 or more spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Aerial mycelium is poorly developed on oatmeal agar. One observer also recorded tabs 2ca (pale yellow) and 3ca (pale orange yellow) from the Red color series as a second color on yeast-malt agar and glycerol-asparagine agar. Reverse side of colony is colorless to pale yellow or grayed yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. However, yellowish reverse pigment is a pH indicator changing from yellow to pink with addition 0.05 M NaOH.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigments or only trace of yellow pigment found in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. sindenensis*, AB184759, 100%; *S. albovinaceus*, AB249958, 100%; *S. griseoplanus*, AY999894, 100%; *S. anulatus*, DQ026637, 100%; *S. globisporus* subsp. *globisporus*, EF178686, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. praecox*, AB184293, 100%; *S. flavofuscus*, AB249935, 100%; *S. fimicarius*, AY999784, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. griseinus*, AB184205, 100%; *S. californicus*, AB184755, 99.9%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.9%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.9%; *S. acrimycini*, AY999889, 99.9%; *S. parvus*, DQ442537, 99.9%; *S. fulvorobeus*, AB184711, 99.8%; *S. lipmanii*, AB184148, 99.8%; *S. microflavus*, DQ445795, 99.8%; *S. cyaneofuscatus*, AB184860, 99.8%; *S. floridae*, AB184656, 99.8%; *S. alboviridis*, AB184256, 99.8%; *S. baarnensis*, EF178688, 99.8%; *S. cinereorectus*, AB184646, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. bacillaris*, AB184439, 99.6%; *S. pulveraceus*, AB184806, 99.6%; *S. halstedii*, EF178695, 99.6%; *S. flavogriseus*, AJ494864, 99.6%; *S. atroolivaceus*, AJ781320, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. albolongus*, AB184425, 99.4%; *S. clavifer*, DQ026670, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. sanglieri*, AB249945, 99.4%; *S. cellulоflavus*, AB184476, 99.4%; *S. yanii*, AB006159, 99.4%; *S. gelaticus*, DQ026636, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. mutomycini*, AB249951, 99.2%; *S. candidus*, DQ026663, 99.2%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cremeus*, AB184124, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19926, ATCC 23960, CBS 943.68, BCRC 13780, DSM 40176, NBRC 12912, INA 10/53, JCM 4415, NRRL B-5425, NRRL-ISP 5176, RIA 1136, VKM Ac-1072.

Sequence accession no. (16S rRNA gene): AB184240.

425. **Streptomyces rubiginosus** (Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 70^{AL} ("*Actinomyces rubiginosus*"

Preobrazhenskaya, Blinov and Ryabova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 134)

ru.bi.gi.no′sus. L. masc. adj. *rubiginosus* rusty, referring to the red-gray-brown color of vegetative mycelium.

Spore chains in Section *Spirales*. Spirals are best developed on salts-starch agar. Aerial mycelium and spore chains may be poorly developed and atypical on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. Mature spore chains generally have 10–50 spores per chain. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigment (yellowish brown, grayed orange brown or yellowish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, salts-starch agar, or glycerol-asparagine agar. There may be a trace of red soluble pigment in oatmeal agar; this pigment is not pH-sensitive.

D-Glucose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Growth on sucrose is less abundant than on other carbon sources. No growth or only trace of growth on raffinose.

Type strain shows the highest sequence similarity to: *S. pseudogriseolus*, DQ442541, 99.4%; *S. gancidicus*, AB184660, 99.4%; *S. capillispiralis*, AB184577, 99.3%; *S. cellulosae*, DQ442495, 99.2%.

Source: not known.

Type strain: ATCC 19927, ATCC 23961, CBS 944.68, DSM 40177, NBRC 12913, INA 11852, JCM 4416, KCTC 9042, NRRL B-3983, NRRL-ISP 5177, RIA 1137, VKM Ac-1089.

Sequence accession no. (16S rRNA gene): AY999810.

426. **Streptomyces rubrogriseus** (*ex* Kurylowicz et al. *in* Prauser 1970) Terekhova 1986, 575[VP] (Effective publication: Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces rubrogriseus*" Kurylowicz et al. *in* Prauser 1970)

Synonym: "*Actinomyces rubrogriseus*" Kurylowicz *et al. in* Prauser (1970).

ru.bro.gri′se.us. L. adj. *ruber -bra -brum* red; N.L. adj. *griseus* gray; N.L. masc. adj. *rubrogriseus* red, gray.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1, oatmeal agar: aerial mycelium is light gray, sometimes pink; substrate mycelium is red; no diffusible pigment. On glycerol-nitrate agar, starch ammonia agar, glycerol-asparagine agar: aerial mycelium is white to light gray; substrate mycelium is yellowish to red, raspberry red; no diffusible pigment. On organic agar 2: aerial mycelium is white to light gray; substrate mycelium is yellowish red to raspberry red; no diffusible pigment. Melanoid pigments are not formed. Antibiotic: prodigiosin-pigment; streptothricin.

Type strain shows the highest sequence similarity to: *S. anthocyanicus*, AB184631, 99.9%; *S. lienomycini*, AJ781353, 99.9%; *S. tricolor*, AB184687, 99.9%; *S. humiferus*, AF503491, 99.7%; *S. coelescens*, AF503496, 99.7%; *S. violaceorubidus*, AJ781374, 99.7%; *S. violaceolatus* AF503497, 99.7%; *S. violaceoruber*, AF503492, 99.7%; *S. tendae*, D63873, 99.6%; *S. coelicoflavus*, AB184650, 99.3%; *S. olivaceus*, AB184743, 99.2%; *S. pactum*, AB184398, 99.2%; *S. ambofaciens*, M27245, 99%; *S. mutabilis*, EF178679, 99%; *S. matensis*, AB184221, 99%; *S. malachitospinus*, AB249954, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 43691, DSM 41477, NBRC 15455, INA 2626, JCM 6927, VKM Ac-1216.

Sequence accession no. (16S rRNA gene): AB184681.

427a. **Streptomyces rutgersensis subsp. rutgersensis** (Waksman and Curtis 1916) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 952[AL] ("*Actinomyces rutgersensis*" Waksman and Curtis 1916, 123)

rut.gers.en′sis. N.L. masc. adj. *rutgersensis* of or belonging to Rutgers; named for Rutgers University, New Brunswick, New Jersey, USA.

Spore chains in Section *Rectiflexibiles* to *Retinaculiaperti*. Short spore chains on this strain are irregularly bent or turned and are not typical of either *Rectiflexibiles* or *Retinaculiaperti* cultures [the characterization of Waksman and Curtis (1916) describes spiral spore chains; atypical spirals are now very rare and reported by only one observer]. Usually only 3–10 spores per chain on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is grayed yellow modified by green on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate color is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast extract broth. Pigments not formed in significant amounts in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth on sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. diastaticus* subsp. *diastaticus*, AB184785, 100%; *S. gougerotii*, AB184742, 100%; *S. intermedius*, AB184277, 99.8%; *S. misionensis*, EF178678, 99.2%; *S. phaeoluteichromatogenes*, AJ391814, 99.1%; *S. matensis*, AB184221, 99%; *S. aureoverticillatus*, AY999774, 99%.

Sequence accession no. (16S rRNA gene): AB184170.

427b. **Streptomyces rutgersensis subsp. castelarensis** corrig. Cercós 1954, 263[AL]

cas.te.lar.en′sis. N.L. masc. adj. *castelarensis* of or belonging to Castelar, Argentina, South America, the source of the organism (from dust).

Spores are short, cylindrical, phalangiform, and may appear roughened. Probably grows well on Czapek's solution agar. Produces camphomycin (two components); NaCl tolerance >4%, but <7%.

Type strain shows the highest sequence similarity to: *Streptomyces sporoclivatus*, AB249934, 99.8; *Streptomyces antimycoticus*, AB184185, 99.8; *Streptomyces geldanamycininus*, DQ334781, 99.6; *Streptomyces melanosporofaciens*, AJ271887, 99.4; *Streptomyces asiaticus*, AB249947, 99.1; *Streptomyces rhizosphaericus*, AB249941, 99.1%.

Source: isolated from dust from Castelar, Argentina, South America.

DNA G+C content (mol%): not known.

Type strain: ATCC 15191, CBS 309.55, BCRC 11879, DSM 40830, NBRC 15875, INA R-43, JCM 4978, RIA 851, VKM Ac-832.

Sequence accession no. (16S rRNA gene): AY508511.

Further comments: the original spelling, *Streptomyces rutgersensis* subsp. *castelarense* (*sic*), has been corrected by Hill et al. (1984).

428. **Streptomyces salmonis** (Baldacci, Farina and Locci 1966) Witt and Stackebrandt 1996, 836[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Streptoverticillium salmonicida*" (Rucker 1949) Baldacci, Farina and Locci 1966, 164; *Streptoverticillium salmonis* Locci, Baldacci and Petrolini Baldan 1969, 27]

sal′mo.nis. L. gen. n. *salmonis* of a salmon.

Good growth on potato-glucose agar (Baldacci et al., 1954). Color: reverse, brick red; aerial mycelium, yellowish white; traces of soluble pigment. On Bacto Czapek agar: traces of growth only. On Casamino acids-Czapek agar (1 g/l Difco vitamin-free Casamino acids, replacing sodium nitrate): very poor, colorless growth. On glucose-asparagine agar (ISP medium 5 with 1% glucose replacing glycerol): good growth. Color: reverse, orange-yellow; aerial mycelium, white with traces of pink and yellow. On glucose-asparagine agar: good growth. Color: reverse orange-yellow; aerial mycelium, whitish with shades of yellow. On yeast extract-malt extract agar: good growth. Color: reverse, brick red; aerial mycelium, yellowish white. On Bacto Emerson agar: good growth. Color: reverse, brick red; aerial mycelium, dirty white; brown soluble pigment. On Bennett agar (1% glucose, 0.1% Bacto beef agar, 0.1% yeast extract, 0.2% peptone, 1.5% agar): good growth. Color: reverse, dirty red; aerial mycelium, dirty white. On Oxoid nutrient agar: medium growth. Color: reverse, brown; aerial mycelium, poor pink; brown soluble pigment. The strain grows also at 37°C, very poor or no aerial mycelium being formed. No growth at 45°C. The type strain exhibits anti-bacterial and anti-fungal activity.

For sequence similarity, see type strain of *Streptomyces hiroshimensis*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: BCRC 12456, DSM 40895, HUT 6085, NBRC 15865, JCM 4083, NRRL B-1472, VKM Ac-944.

Sequence accession no. (16S rRNA gene): X53169.

Further comments: according to Hatano et al. (2003), *Streptomyces salmonis* (Baldacci et al. 1966) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

429. **Streptomyces sampsonii** (Millard and Burr 1926) Waksman *in* Waksman and Lechevalier 1953, 155[AL] ("*Actinomyces sampsonii*" Millard and Burr 1926, 614)

samp.so′ni.i. N.L. gen. masc. n. *sampsonii* of Sampson, a patronymic.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long and flexuous with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (1ba-2ba, pale yellow, or 1db, pale yellowish green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; or sometimes in the Gray color series (2dc, yellowish gray) on yeast-malt agar and salts-starch agar. Reverse side of colony with no distinctive pigments (pale yellow to light olive brown on salts-starch agar and glycerol-asparagine agar; strong yellow to orange-yellow or yellowish brown on yeast-malt agar and oatmeal agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth with iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. albidoflavus*, AB184255, 99.9%; *S. odorifer*, Z76682, 99.9%; *S. daghestanicus*, DQ442497, 99.8%; *S. felleus*, AB184129, 99.8%; *S. hydrogenans*, AB184868, 99.8%; *S. violascens*, AY999737, 99.8%; *S. limosus*, AB184147, 99.8%; *S. griseus* subsp. *solvifaciens*, AB249915, 99.7%; *S. canescens*, AB184117, 99.7%; *S. koyangensis*, AY079156, 99.5%; *S. champavatii*, DQ026642, 99.3%.

DNA G+C content (mol%): not known.

Type strain: ATCC 25495, CBS 955.69, BCRC 13705, DSM 40394, NBRC 13083, JCM 4515, NRRL B-12325, NRRL-ISP 5394, RIA 1275, VKM Ac-851.

Sequence accession no. (16S rRNA gene): D63871.

430. **Streptomyces sanglieri** Manfio, Atalan, Zakrzewska-Czerwinska, Mordarski, Rodríguez, Collins and Goodfellow 2003b, 1219[VP] (Effective publication: Manfio, Atalan, Zakrzewska-Czerwinska, Mordarski, Rodríguez, Collins and Goodfellow 2003a, 252.)

san.gli.e′ri. N.L. gen. masc. n. *sanglieri* of Sanglier, named in honor of Jean-Jacques Sanglier, a Belgian biotechnologist.

Aerobe, Gram-stain-positive, mesophilic actinomycetes which form extensively branched substrate and aerial hyphae. Spiral and open loops of smooth-surfaced spores are evident on aerial hyphae. A gray aerial spore mass and a reddish-orange substrate mycelium are formed on modified Bennett's, glycerol-asparagine, oatmeal, and yeast extract-malt extract agars; a reddish-orange pigment is produced on oatmeal agar. Hippurate is hydrolyzed and nitrate is reduced. Cleaves methoxysuccinyl-L-alanine-L-lysine-7AMC, L-citrulline-7AMC, *N*-acetyl-L-phenylalanine-L-arginine-7AMC (endopeptidase substrates), L-cysteine-7AMC (exopeptidase substrates), 4MU-*N*-acetyl-β-D-glucosaminde, 4MU-2-deoxy-β-D-glucopyranoside and 4MU-β-D-xyloside (glycosides), and 4MU-oleate (organic ester), but not L-phenylalanine-7AMC (endopeptidase substrate), L-glutamine-7AMC (exopeptidase substrates), 4MU-α-D-mannopyranoside (glycoside), or 4MU-elaidate (organic ester). L-Phenylalanine is used as sole carbon and nitrogen source but not L-histidine, L-hydroxyproline, or potassium nitrate. Does not use dextran, *myo*-inositol, inulin, mannitol, or pyruvate as sole sources of carbon for energy and growth. Grows between 10 and 35°C, but not at 45°C, or in the presence of sodium azide (0.01%, w/v), sodium chloride (7.0%, w/v), or neomycin sulfate (50 μg/ml) but is sensitive to oleandomycin phosphate (100 μg/ml).

Type strain shows the highest sequence similarity to: *S. atratus*, DQ026638, 100%; *S. yanii*, AB006159, 99.7%; *S. pulveraceus*, AB184806, 99.7%; *S. gelaticus*, DQ026636, 99.5%; *S. badius*, AY999783, 99.4%; *S. pluricolorescens*, DQ442540, 99.4%; *S. sindenensis*, AB184759, 99.4%; *S. mediolani*, AB184674, 99.4%; *S. griseinus*, AB184205, 99.4%; *S. rubiginosohelvolus*, AB184240, 99.4%; *S. albovinaceus*, AB249958, 99.3%; *S. globisporus* subsp. *globisporus*, EF178686, 99.3%; *S. flavofuscus*, AB249935, 99.3%; *S. fimicarius*, AY999784, 99.3%; *S. anulatus*, DQ026637, 99.3%; *S. praecox*, AB184293, 99.3%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.3%; *S. argenteolus*, AB045872, 99.3%; *S. parvus*, DQ442537, 99.3%; *S. cinereorectus*, AB184646, 99.3%; *S. griseoplanus*, AY999894, 99.3%; *S. californicus*, AB184755, 99.3%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.3%; *S. alboviridis*, AB184256, 99.2%; *S. griseolus*, AB184768, 99.2%; *S. baarnensis*, EF178688, 99.2%; *S. lipmanii*, AB184148, 99.2%; *S. cyaneofuscatus*, AB184860, 99.2%; *S. fulvorobeus*, AB184711, 99.2%; *S. acrimycini*, AY999889, 99.2%; *S. flavovirens*, DQ026635, 99.2%; *S. microflavus*, DQ445795, 99.2%; *S. floridae*, AB184656, 99.2%; *S. halstedii*, EF178695, 99.1%; *S. flavogriseus*, AJ494864, 99.1%; *S. luridiscabiei*, AF361784, 99.1%; *S. nitrosporeus*, EF178680, 99.1%; *S. griseus* subsp. *griseus*, AY207604, 99%; *S. bacillaris*, AB184439, 99%.

Source: isolated from soil taken from meadow hay plots.

DNA G+C content (mol%): 70–76.

Type strain: A46R51, DSM 41791, JCM 12607, NBRC 100784, NCIMB 13929.

Sequence accession no. (16S rRNA gene): AB249945.

431. **Streptomyces sannanensis** Iwasaki, Itoh and Mori 1981, 283[VP]

san.nan.en′sis. N.L. masc. adj. *sannanensis* of or pertaining to Sannan, a town in Japan.

Spore chains in Section *Spirales*. Mature spore chains are generally moderately short, often with 20 or more spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the gray color series on sucrose-nitrate agar, glucose-asparagine agar, inorganic salts-starch agar, and oatmeal agar. Reverse side of colony with no distinctive pigments (colorless to buff in color) on all media. Diffusible pigment: melanoid pigments are not formed in peptone-yeast extract-iron agar, tyrosine agar, or tryptone-yeast extract broth. No pigment other than a trace of yellow is produced in the media used. Starch is hydrolyzed and gelatin is liquefied. Does not grow in skim milk medium. Melanoid pigment is not produced. No growth or only traces of growth with L-arabinose, D-xylose, D-glucose, D-fructose, sucrose, iso-inositol, L-rhamnose, raffinose, or D-mannitol with Pridham and Gottlieb's basal mineral salts agar. On $CuSO_4$-free Pridham and Gottlieb's basal mineral salts agar and Czapek's solution agar, D-xylose and D-glucose are utilized for growth; D-glucose gives only faint growth. Mesophilic (growth range is from 17–37°C; temperature for optimum growth is between 27 and 34°C). Cell-wall composition: LL-A_2pm occurs in whole-cell hydrolysates. The cell-wall composition is believed to be of Type I. Produces sannamycins.

Type strain shows the highest sequence similarity to: *S. mauvecolor*, AB184532, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: KC-7038, ATCC 31530, DSM 41705, NBRC 14239, JCM 9651, KCTC 9770.

Sequence accession no. (16S rRNA gene): AB184579.

432. **Streptomyces sapporonensis** (Locci 1985) Witt and Stackebrandt 1996, 836[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Streptomyces sapporonensis*" Sakai and Miyoshi 1972; "*Streptoverticillium sapporonense*" (*ex* Arai 1976) Locci 1985, 232]

sap.po.ro.nen′sis. N.L. masc. adj. *sapporoensis* of or pertaining to Sapporo, a town in Japan.

Reddish spore mass, aerial mycelium is cottony. Melanin pigment is not produced. Acid is produced from D-galactose and *myo*-inositol, but not from D-fructose, trehalose, or D-ribose. L-Methionine, shikimic acid, and DL-α-aminobutyric acid are utilized, but not coumarin, mannitol, melibiose, proline, raffinose, or sorbitol. Degrades citrate, but not esculin or L-tyrosine. H_2S production. No NO_3^- reduction. Resistant to carbenicillin (100 μg/ml), cephaloridine (30 μg/ml), cephalotin (30 μg/ml), and colistin (30 μg/ml). *Aspergillus niger* and *Bacillus subtilis* are inhibited, *Candida albicans* is not.

Type strain shows the highest sequence similarity to: *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99.5%; *S. varsoviensis*, DQ026653, 99.5%; *S. abikoensis*, AB184537, 99.5%; *S. ehimensis*, AY999834, 99.4%; *S. lilacinus*, AB184819, 99.3%; *S. luteireticuli* AB249969, 99.2%; *S. mobaraensis*, DQ442528, 99.1%; *S. caeruleus*, EF178675, 99.1%; *S. lavenduligriseus*, DQ442515, 99%; *S. hiroshimensis*, AB184789, 99%; *S. thioluteus* AB184753, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 21532, DSM 41675, NBRC 13823, JCM 4934.

Sequence accession no. (16S rRNA gene): AB184508.

Further comments: according to Hatano et al. (2003), *Streptomyces sapporonensis* (Locci and Schofield 1989) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces cinnamoneus* (Benedict et al. 1952) Witt and Stackebrandt 1991.

433. **Streptomyces scabiei** corrig. (*ex* Thaxter 1891) Lambert and Loria 1989b, 391[VP] ("*Oospora scabies*" Thaxter 1891; "*Actinomyces scabies*" Güssow 1914; "*Streptomyces scabies*" Waksman and Henrici 1948)

sca′bi.ei. L. gen. n. *scabiei* of mange, in reference to the ability to cause potato scab.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately short with 3–10, or sometimes more than 10, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is yellow to yellow brown is usually modified by green to light grayish olive, olive, or olive brown on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Substrate mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow or greenish yellow pigment may be found in the medium in yeast-malt agar and oatmeal agar, but not in salts-starch agar or glycerol-asparagine agar; this pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth with sucrose, iso-inositol, and raffinose.

Type strain shows the highest sequence similarity to: *S. europaeiscabiei*, AY207598, 99.8%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: RL-34, ATCC 49173, CIP 105438, DSM 41658, ICMP 12542, JCM 7914.

Sequence accession no. (16S rRNA gene): D63862.

Further comments: the original spelling of the specific epithet, *scabies* (*sic*), has been corrected by Trüper and De'Clari (1997).

434. **Streptomyces scabrisporus** Xu, Takahashi, Seino, Iwai and Ōmura 2004b, 580[VP]

sca.bri.spo′rus. L. adj. *scaber -bra -brum* scabby, rough; N.L. n. *spora* spore; N.L. masc. adj. *scabrisporus* referring to the rugose surface of the spores.

Mature spore chains are spiral, with more than 20 spores per chain. Spores are cylindrical in shape, 0.6–0.8 × 1.2–1.6 µm in diameter; the spore surface is rugose. Substrate and aerial mycelia are produced. The reverse sides of colonies are colorless to light ivory. The aerial mass on some agar media, such as water agar, oatmeal agar, and 1/10 V8 juice agar, is gray. Mycelia do not fragment into coccoid or bacillary elements. Melanoid or soluble pigments are not produced on any medium tested. Starch is weakly hydrolyzed, gelatin is not liquefied and milk is weakly coagulated. D-Glucose, D-fructose, D-xylose, *myo*-inositol, and rhamnose are utilized for growth, but D-mannitol, raffinose, and melibiose are not; little if any growth is observed with sucrose, L-arabinose, or salicin. Menaquinone composition is MK-9(H_4), MK-9(H_2), and MK-9(H_6) in the ratio 12:4:3.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. chrestomyceticus* ATCC 14947^T, 54%.

Source: the type strain was isolated from a soil sample collected from Ushiku-cho, Ibaraki Prefecture, Japan.

DNA G+C content (mol%): 70.6.

Type strain: KM-4927, JCM 11712, NBRC 100760, NRRL B-24202.

Sequence accession no. (16S rRNA gene): AB030585.

435. **Streptomyces sclerotialus** (Thirumalachar 1955) Pridham 1970, 44[AL] (*Chainia antibiotica* Thirumalachar 1955, 935)

scle.rot.i′a.lus. N.L. neut. n. *sclerotium* sclerotium; N.L. masc. adj. *sclerotialus* pertaining to sclerotia.

Spore chains in Section *Spirales*. Spirals are best developed on salts-starch agar. Aerial mycelium may be poorly developed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, but some spirals or chains can usually be found on these media. Spore surface is smooth. One of three observers reports sclerotia and fragmentation of substrate mycelium on glycerol-asparagine agar in 21 d. A second observer reports "globular sporangia" on yeast-malt agar, oatmeal agar, and salts-starch agar and "coremia" on yeast-malt agar in 7–14 d. Scanning electron microscopy shows coalesced masses of spores.

Color of colony: aerial mycelium is generally poorly developed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Sporulating aerial mycelium adequate for color determination may be formed on salts-starch agar; it is in the White color series. One observer reports aerial mycelium in the Yellow color series (2fb, light yellowish red; 1db, pale yellow green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this may be the color of the vegetative (substrate mycelium) growth. Reverse side of colony with no distinctive pigments (orange yellow to yellowish brown on yeast-malt agar, light grayish yellow or light yellowish brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. rimosus* subsp. *rimosus*, AB045883, 99.4%; *S. olivaceiscleroticus*, AJ621606, 99.2%; *S. niger*, AJ621607, 99.2%; *S. chresto-*

myceticus, AJ621609, 99.1%; *S. rimosus* subsp. *paromomycinus*, AJ621610, 99.1%; *S. erumpens*, AJ621603, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 15721, CBS 167.62, BCRC 13307, DSM 43032, IFM 1141, NBRC 12246, NBRC 13356, NBRC 13904, JCM 3039, JCM 4828, KCTC 9065, NRRL B-2317, NRRL-ISP 5269, RIA 1317, VKM Ac-1909.

Sequence accession no. (16S rRNA gene): AJ621608.

Further comments: Streptomyces sclerotialus Pridham 1970 and *Chainia antibiotica* Thirumalachar 1955 have the same type strain and therefore are homotypic synonyms [Rules 24a and 24b(1) of the *Bacteriological Code* (1990 Revision)].

436. **Streptomyces scopiformis** Li, Lanoot, Zhang, Vancanneyt, Swings and Liu 2002a, 1632[VP]

sco.pi.for′mis. L. fem. n. *scopa* a broom; L. adj. suffix *-formis -is -e* (from L. n. *forma* figure, shape, appearance) -like, in the shape of; N.L. masc. adj. *scopiformis* in the form of a broom, referring to the structure of the spore chains.

Rectiflexibiles chains of roundish, spiny-surfaced spores (0.7–0.8 μm) are arranged in fastigiate form. Spore mass is gray or blue-gray, the reverse is blue to gray-blue. Substrate hyphae are extensively branching, septate, and swollen. Diffusible pigment is not formed. Tests for esculin, starch, dextrin, elastin, nitrate reduction, and gelatin are positive and tests for hippurate, cellulose, and lipolysis are negative. Utilizes L-arabinose, D-fructose, D-galactose, D-glucose, D-maltose, L-rhamnose, D-xylose, D-sucrose, dulcitol, *myo*-inositol, melibiose, trehalose, sodium acetate, and sodium citrate as sole carbon sources but not D-mannitol, D-raffinose, adonitol, methyl α-glucoside, iso-erythritol, or inulin. Grows in presence of penicillin G, biomycin, phenol, and ethanol, at 20–45°C and at pH 5–10 but not in the presence of bacteracin, lysozyme, sodium azide, or methyl violet, or at 10 or 50°C or at pH 4.0 or 11.0. Cell-wall type I, phospholipid type PII and menaquinone MK-9($H_{4,6}$) are detected. The fatty acids are type II. Mycolic acids are not present.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. ambofaciens* AS 41528^T, 13±1%; *S. coerulescens* JCM 4358^T, 34±3%; *S. caelestis* JCM 218^T, 23±4%; *S. nogalater* JCM 4799^T, 31±4%; *S. intermedius* JCM 4483^T, 26±3%; *S. albidoflavus* JCM 4446^T, 19±6%.

Source: not known.

DNA G+C content (mol%): 71.0.

Type strain: A25, AS 4.1331, DSM 41825, JCM 12114, LMG 20251, NBRC 100244.

Sequence accession no. (16S rRNA gene): AB249927.

437. **Streptomyces seoulensis** Chun, Youn, Yim, Lee, Kim, Hah and Kang 1997, 495[VP]

se.oul.en′sis. N.L. masc. adj. *seoulensis* of or belonging to Seoul, Republic of Korea, the geographical origin of the species.

Long-chain *Rectiflexibiles* spores with smooth surfaces are produced. Forms a yellow substrate mycelium on glycerol-asparagine agar and a gray aerial mycelium and spores on inorganic salts-starch agar. Verticils are not present. Diffusible pigments are not produced on ISP 5 medium. Melanin is not produced on peptone-yeast extract-iron agar and tyrosine agar. It utilizes L-histidine as sole nitrogen source but not DL-α-amino-*n*-butyric acid, L-cysteine, L-valine, L-phenylalanine, L-hydroxyproline, or potassium nitrate. Uses D-fructose, lactose, mannitol, D-melibiose, raffinose, L-rhamnose, salicin, sodium pyruvate, sucrose, and D-glucose as sole sources of carbon, but not adonitol, L-arabinose, dextran, *myo*-inositol, melezitose, sodium acetate, sodium citrate, sodium propionate, or xylitol. Tests for lecithinase, lipolysis, pectin hydrolysis, and H_2S production are positive but not those for hippurate hydrolysis or nitrate reduction. Degrades allantoin, arbutin, and elastin but not guanine, xanthine, or xylan. Grows in the presence of potassium tellurite, rifampin, and penicillin G but not at 45°C or in the presence of sodium chloride, sodium azide, thallous acetate, neomycin, or oleandomycin. The cell wall contains LL-A_2pm and no diagnostic sugars are present in the cell-wall fraction (chemotype I). Phosphatidylethanolamine, phosphatidylinositol, diphosphatidylglycerol, and phosphatidylinositol mannosides are present in the polar lipid fraction (phospholipid type II). The fatty acids are mainly saturated straight-chain as well as iso- and anteiso-branched fatty acids (fatty acid type 2c). Activity is not exhibited against *Aspergillus niger*, *Bacillus subtilis*, *Candida albicans*, *Micrococcus luteus*, *Saccharomyces cerevisiae*, or *Streptomyces murinus*.

Type strain shows the highest sequence similarity to: *S. recifensis*, AB184165, 99.8%; *S. griseoluteus*, AY999751, 99.7%.

Source: isolated from Seoul, Korea.

DNA G+C content (mol%): 68.0.

Type strain: IMSNU-1 (deposited in the Institute of Microbiology, Seoul National University, under accession number IMSNU 21266), CIP 105312, NBRC 16255, NBRC 16668, JCM 10116.

Sequence accession no. (16S rRNA gene): AB249970.

438. **Streptomyces septatus** (Locci, Baldacci and Petrolini Baldan 1969) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptoverticillium septatum* Locci, Baldacci and Petrolini Baldan 1969, 59)

sep.ta′tus. L. masc. adj. *septatus* surrounded by a bulwark, fenced.

Spore chains in Section Umbellate Monoverticillate (=*Streptomyces Verticillati*, biverticillate). Mature spore chains are generally short, with 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (white is also present). Nearest matching color tabs in the Yellow color series are 2db and 2ba, pale yellow, and 1cb, pale yellow green. Nearest matching tabs in the Red color series are 4ec and 5cb, grayish yellowish pink, and 3ca, pale orange yellow. Red aerial mycelium may sometimes occur as scattered tufts of longer aerial hyphae in a yellow or white background.

Reverse side of colony with no distinctive pigments (olive brown to strong brown on yeast-malt agar; pale grayish yellow on oatmeal agar and salts-starch agar; grayish yellow to pale yellowish green on glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar in 14 d or a trace of yellow may sometimes be seen in yeast-malt agar, oatmeal agar, and salts-starch agar in 21 d.

D-Glucose and iso-inositol are utilized for growth. Reports vary on growth on D-fructose, but utilization of this sugar is doubtful. No growth or only traces of growth with L-arabinose, D-xylose, D-mannitol, rhamnose, sucrose, and raffinose.

For sequence similarity, see type strain of *Streptomyces griseocarneus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27464, CBS 772.72, BCRC 11895, CECT 3251, DSM 40577, NBRC 13471, JCM 4547, JCM 4829, NCIMB 12982, NRRL 2974, NRRL-ISP 5577, RIA 1432, VKM Ac-888.

Sequence accession no. (16S rRNA gene): AB184883.

Further comments: according to Hatano et al. (2003), *Streptomyces septatus* (Locci et al. 1969) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces griseocarneus* (Benedict et al. 1950) Witt and Stackebrandt 1991.

439. **Streptomyces setonii** (Millard and Burr 1926) Waksman *in* Waksman and Lechevalier 1953, 107[AL] ("*Actinomyces setonii*" Millard and Burr 1926, 604)

se.to'ni.i. N.L. gen. masc. n. *setonii* of Seton, named for a person, Seton (Probably R.S. Seton of the Harris Insitute, Preston, England).

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow (2ba, pale yellow) or Gray (2dc, yellowish gray) color series on yeast-malt agar and glycerol-asparagine agar; White color series on oatmeal agar and salts-starch agar. Reverse side of colony with no distinctive pigments (pale or grayish yellow to light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth with iso-inositol, sucrose, and raffinose.

For sequence similarity, see type strain of *Streptomyces griseus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25497, CBS 105.27, CBS 957.69, CFBP 4549, CIP 105279, DSM 40395, ICMP 12543, NBRC 13085, JCM 4226, JCM 4516, KCTC 9144, NRRL B-2555, NRRL-ISP 5395, RIA 1277.

Sequence accession no. (16S rRNA gene): D63872.

Further comments: according to Liu et al. (2005b), *Streptomyces setonii* (Millard and Burr 1926) Waksman 1953 is a later heterotypic synonym of *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 emend. Liu et al. 2005b.

440. **Streptomyces showdoensis** Nishimura, Mayama, Komatsu, Kato, Shimaoka and Tanaka 1964, 150[AL]

show.do.en'sis. N.L. masc. adj. *showdoensis* of or belonging to Shodo, an island in Kagawa Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long, with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. White aerial mycelium may also be seen on these media. Most representative color tabs from the Gray color series are 2dc, yellowish gray, and 3ge, light grayish yellowish brown, and from the Yellow color series, 2db and 2ba, pale yellow. Reverse side of colony with no distinctive pigments (orange yellow or yellowish brown on yeast-malt agar; pale or grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, and weakly in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-xylose, and D-fructose are utilized for growth. Utilization of L-arabinose and sucrose is doubtful. No growth or only traces of growth with iso-inositol, D-mannitol, rhamnose, or raffinose.

Type strain shows the highest sequence similarity to: *S. viridobrunneus*, AJ781372, 100%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99.5%; *S. roseoviridis*, AB184239, 99.4%; *S. tanashiensis*, AJ781362, 99.1%; *S. nashvillensis*, AB184286, 99.1%; *S. violaceorectus*, AB184314, 99.1%; *S. vietnamensis*, DQ311081, 99%; *S. bikiniensis*, X79851, 99%.

Source: isolated from soil from Shodo, an island in Kagawa Prefecture, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 15105, CBS 718.72, BCRC 11868, DSM 40504, NBRC 13417, JCM 4830, NRRL B-12430, NRRL-ISP 5504, RIA 1378, VKM Ac-1219.

Sequence accession no. (16S rRNA gene): AB184389.

441. **Streptomyces sindenensis** Nakazawa and Fujii 1957, 109[AL]

sin.den.en'sis. N.L. masc. adj. *sindenensis* of or belonging to Sinda Village, Osaka Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are short, often with only 3–10 spores per chain (longer chains may be found on impression mounts or electron micrographs) This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color is difficult to determine because sporulating aerial mycelium is poorly developed on ISP media. When sporulation occurs, it is usually in the White or Red (5cb, grayish yellowish pink) color series on yeast-malt agar and in the White or Yellow color series on oatmeal agar. When present, sporulation aerial mycelium is in the White color series on salts-starch agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless or pale grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth with sucrose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. albovinaceus*, AB249958, 100%; *S. griseoplanus*, AY999894, 100%; *S. anulatus*, DQ026637, 100%; *S. globisporus* subsp. *globisporus*, EF178686, 100%; *S. pluricolorescens*, DQ442540, 100%; *S. praecox*, AB184293, 100%; *S. flavofuscus*, AB249935, 100%; *S. fimicarius*, AY999784, 100%; *S. mediolani*, AB184674, 100%; *S. badius*, AY999783, 100%; *S. griseinus*, AB184205, 100%; *S. rubiginosohelvolus*, AB184240, 100%; *S. californicus*, AB184755, 99.9%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.9%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.9%; *S. acrimycini*, AY999889, 99.9%; *S. parvus*, DQ442537, 99.9%; *S. fulvorobeus*, AB184711, 99.8%; *S. lipmanii*, AB184148, 99.8%; *S. microflavus*, DQ445795, 99.8%; *S. cyaneofuscatus*, AB184860, 99.8%; *S. floridae*, AB184656, 99.8%; *S. alboviridis*, AB184256, 99.8%; *S. baarnensis*, EF178688, 99.8%; *S. cinereorectus*, AB184646, 99.8%; *S. griseus* subsp. *griseus*, AY207604, 99.7%; *S. griseolus*, AB184768, 99.7%; *S. luridiscabiei*, AF361784, 99.7%; *S. flavovirens*, DQ026635, 99.7%; *S. argenteolus*, AB045872, 99.7%; *S. bacillaris*, AB184439, 99.6%; *S. pulveraceus*, AB184806, 99.6%; *S. halstedii*, EF178695, 99.6%; *S. flavogriseus*, AJ494864, 99.6%; *S. atroolivaceus*, AJ781320, 99.5%; *S. olivoviridis*, AB184227, 99.5%; *S. finlayi*, AY999788, 99.5%; *S. nitrosporeus*, EF178680, 99.5%; *S. albolongus*, AB184425, 99.4%; *S. clavifer*, DQ026670, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. sanglieri*, AB249945, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. yanii*, AB006159, 99.4%; *S. gelaticus*, DQ026636, 99.3%; *S. atratus*, DQ026638, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. mutomycini*, AB249951, 99.2%; *S. candidus*, DQ026663, 99.2%; *S. spiroverticillatus*, AB184814, 99.1%; *S. cremeus*, AB184124, 99.1%.

Source: isolated from soil from Sinda Village, Osaka Prefecture, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 23963, CBS 946.68, BCRC 11887, DSM 40255, NBRC 12915, NBRC 3399, JCM 4164, JCM 4669, NRRL B-1866, NRRL-ISP 5255, RIA 1181.

Sequence accession no. (16S rRNA gene): AB184759.

442. **Streptomyces sioyaensis** Nishimura, Okamoto, Mayama, Ohtsuka, Nakajima, Tawara, Shimohira and Shimaoka 1961, 257[AL]

si.o.ya.en′sis. N.L. masc. adj. *sioyaensis* of or belonging to Sioya, Kobe, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales*. Mature spore chains generally have 10–50 spores per chain; longer chains are sometimes observed. Morphology can be observed on oatmeal agar and glycerol-asparagine agar in 14–21 d. Typical aerial mycelium may develop slowly or fail to develop on yeast-malt agar and salts-starch agar. Spore surface is smooth. One observer reports disintegration of spiral spore chains in dark liquid droplets.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayed yellow or grayed yellow modified by green) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar and tyrosine agar. Trace of yellow pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is not pH-sensitive.

D-Glucose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. No growth or only trace of growth on L-arabinose and rhamnose.

Type strain shows the highest sequence similarity to: *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.6%; *S. nigrescens*, DQ442530, 99.5%; *S. libani* subsp. *libani*, AB184414, 99.5%; *S. tubercidicus*, AJ621612, 99.5%; *S. lydicus*, Y15507, 99.3%; *S. chattanoogensis*, AJ621611, 99.3%; *S. libani* subsp. *rufus*, AJ781351, 99.2%; *S. misakiensis*, AB217605, 99.2%; *S. caniferus*, AB184640, 99.2%; *S. catenulae*, AJ621613, 99.2%; *S. erumpens*, AJ621603, 99.2%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.2%; *S. ochraceiscleroticus*, AB184094, 99.1%; *S. purpurogeneiscleroticus*, AJ621604, 99.1%; *S. platensis*, AB045882, 99.1%; *S. chrestomyceticus*, AJ621609, 99%; *S. albospinus*, AB184527, 99%; *S. monomycini*, DQ445790, 99%; *S. auratus*, AJ391816, 99%; *S. rimosus* subsp. *paromomycinus*, AJ621610, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 13989, ATCC 19810, CBS 563.68, BCRC 11878, DSM 40032, NBRC 12820, JCM 4418, KCTC 9043, NRRL B-5408, NRRL-ISP 5032, RIA 1090, UNIQEM 197, VKM Ac-1260.

Sequence accession no. (16S rRNA gene): DQ026654.

443. **Streptomyces sodiiphilus** Li, Zhang, Zhang, Tang, Yu, Xu and Jiang 2005, 1332[AL]

so.di.i′phi.lus. N.L. n. *sodium -i* sodium; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. masc. adj. *sodiiphilus* sodium ion-loving, referring to the characteristic of Na^+-dependent growth.

Long or short chains of spores are straight to flexuous and spores are nonmotile. Both vegetative and aer-

ial hyphae are well-developed and not fragmented. No diffusible pigments are produced except on nutrient agar medium (pale orange-yellow). Positive for gelatin liquefaction and nitrate reduction, but negative for urease, melanin production, starch hydrolysis, H_2S production, milk coagulation, and milk peptonization. Sodium acetate and rhamnose can be used as sole carbon sources for growth, but not most other carbon sources, such as lactose, maltose, fructose, xylose, ribose, arabinose, sucrose, glucose, galactose, sodium citrate, cellobiose, raffinose, mannitol, sorbitol, glycerol, and starch. Grows optimally at 28°C and in ISP medium 2 with 3% NaCl and pH 9.0–10.0. Cell wall contains LL-A_2pm and glycine. Whole-cell hydrolysates mainly contain galactose and glucose and no diagnostic sugars. Predominant menaquinones are MK-9(H_4) (13%), MK-9(H_6) (68%), and MK-9(H_8) (19%), and the diagnostic phospholipid is phosphatidylethanolamine. Major fatty acid components are $C_{15:0}$ anteiso (16.46%), $C_{17:0}$ anteiso (13.30%), and $C_{16:0}$ iso (31.32%).

Type strain shows no sequence similarity over 99%.

Source: the type strain was isolated from soil sample collected from Chaka salt lake, Qinghai Province, China.

DNA G+C content (mol%): 70.5.

Type strain: YIM 80305, CCTCC AA 203015, CIP 107975, JCM 13581.

Sequence accession no. (16S rRNA gene): AY236339.

444. **Streptomyces somaliensis** (Brumpt 1906) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 965[AL] ("*Indiella somaliensis*" Brumpt 1906, 555)

so.ma.li.en′sis. N.L. masc. adj. *somaliensis* of or pertaining to Somalia.

Spore chains in Section *Rectiflexibiles*; flexuous chains are most common. Mature spore chains generally have 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (2db or 2ba, pale yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (one observer selected color tab 3ca, pale orange yellow, from the Red color-wheel as the most representative color). Aerial mycelium is often poorly developed on much of the culture surface on ISP media. Good sporulation in the Yellow color series was observed on Czapek's agar. Reverse side of colony with no distinctive pigments (grayish yellow to grayish greenish yellow and light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, D-mannitol, and D-fructose are utilized for growth. No growth or only trace of growth iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. coeruleoprunus*, AB184651, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 33201, DSM 40738, JCM 12659, IMRU 1274, NCTC 11332.

Sequence accession no. (16S rRNA gene): AJ007403.

445. **Streptomyces sparsogenes** Owen, Dietz and Camiener 1963, 772[AL] emend. Goodfellow, Kumar, Labeda and Sembiring 2008, 5 (Effective publication: Goodfellow, Kumar, Labeda and Sembiring 2007, 192.) ("*Streptomyces sparsogenes* var. *sparsogenes*" Owen, Dietz and Camiener 1963, 772)

spar.so′ge.nes. L. part. adj. *sparsus* scattered; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *sparsogenes* scattered producing, probably referring to the sparse formation of aerial mycelium.

Spore chains in Section *Spirales*. Aerial hyphae and spirals may emerge from coremia-like structures. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology may be seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, although sporulation is not always uniformly good on these media. One observer notes autolysis or lysis on media in 14 d. Spore surface is spiny; individual spores are indistinct.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray or 3fe, light brownish gray to 5fe, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; aerial mycelium in the Yellow color series (2ba, pale yellow) may also be seen on yeast-malt agar and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (light or pale yellow to moderate yellow or orange-yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth. Utilization of iso-inositol is doubtful.

Type strain shows the highest sequence similarity to: *S. cuspidosporus*, AB184090, 99.9%.*Source:* not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25498, CBS 672.69, CBS 958.69, BCRC 12085, DSM 40356, NBRC 13086, JCM 4517, LMG 5985, NCIMB 9449, NRRL 2940, NRRL-ISP 5356, RIA 1278, VKM Ac-1744.

Sequence accession no. (16S rRNA gene): AB184301.

446. **Streptomyces specialis** Kämpfer, Huber, Buczolits, Thummes, Grün-Wollny and Busse 2008, 2605[VP]

spe.ci.a′lis. L. masc. adj. *specialis* particular, special, because of the unusual quinone type and the separate phylogenetic position.

Forms extensively branched substrate mycelium and aerial hyphae that differentiate into spiral chains of spores. Spore chains consist of up to 15 spores. Spores are elliptical or short rods. Good growth on all ISP media (ISP 1 through 5, according to Shirling and Gottlieb,

1966) after 2 weeks incubation at 28°C. On all media, a pinkish white aerial mycelium and a pale yellow substrate mycelium is produced. The isolate produces a black pigment on all tested ISP media. *N*-Acetyl-D-glucosamine, D-glucose, D-gluconate, D-ribose, D-sucrose, adonitol, D-arabitol, D-sorbitol, iso-inositol, propionate, glutarate, butyrate, isobutyrate, iso-valeric acid, L-arginine, and L-asparagine are utilized for growth. The following carbon sources are not utilized: L-arabinose, cellobiose, D-fructose, D-galactose, maltose, D-mannose, melibiose, L-rhamnose, salicin, and D-xylose. Good growth occurs on nutrient agar and medium 65 at 25–30°C; Major fatty acids are $C_{16:0}$ iso, $C_{16:0}$, $C_{17:1}$ anteiso ω9*c*, $C_{17:0}$ anteiso, and $C_{16:1}$ iso H. The quinone system is composed of the major compound MK-10(H_4) and moderate to minor amounts of MK-10(H_6), MK-9(H_4), and MK-9(H_6). In the polar lipid profile, diphosphatidylglycerol is predominant. Phosphatidylethanolamine, phosphatidylglycerol, and phosphatidylinositol are present in moderate amounts and phosphatidylinositol mannosides, an unknown aminolipid, an unknown phospholipid, and three unknown polar lipids are present in minor to trace amounts.

Type strain shows no sequence similarity over 99%.

Source: isolated from soil.

DNA G+C content (mol%): not known.

Type strain: GW41-1564, DSM 41924, CCM 7499.

Sequence accession no. (16S rRNA gene): AM934703.

447. **Streptomyces spectabilis** Mason, Dietz and Smith 1961, 118[AL]

spec.ta′bi.lis. L. masc. adj. *spectabilis* visible, notable, remarkable.

Spore chains in Section *Rectiflexibiles* with straight to flexuous spore chains. Distribution of sporophores sometimes suggests verticillate morphology, but true whorls or verticils are not produced. Mature spore chains are long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (7ca or 5ca, light yellowish pink; 5gc, light reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. White aerial mycelium is sometimes produced. Reverse side of colony with distinctive reddish orange pigments on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is changed only slightly by the addition of 0.05 M NaOH or HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and sometimes in tryptone-yeast broth, but not in tyrosine agar. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and raffinose are utilized for growth. Utilization of rhamnose is doubtful. No growth or only traces of growth with sucrose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27465, CBS 725.72, BCRC 12648, CECT 3146, DSM 40512, NBRC 13424, NBRC 15441, JCM 4308, JCM 4832, KCTC 9218, LMG 5986, NCIMB 9733, NRRL 2494, NRRL-ISP 5512, RIA 1385.

Sequence accession no. (16S rRNA gene): AB184393.

448. **Streptomyces speibonae** Meyers, Porter, Omorogie, Pule and Kwetane 2003, 804[VP]

spei.bo′na.e. L. n. *spes -ei* hope; L. adj. *bonus* good; N.L. gen. n. *speibonae* of good hope, to indicate Cape Town, the Cape of Good Hope, South Africa, the geographical location from which the type strain was isolated.

Spirales-type spore chains with hairy spore sheaths are produced. Forms gray aerial mycelium. The color of the substrate mycelium is not pH-sensitive. Verticils are not present. The mycelium does not fragment. No diffusible pigments are produced on glycerol-asparagine agar or on any other medium. Melanin pigment is produced on both peptone-yeast extract-iron agar and tyrosine agar. Although growth on inorganic salts-starch agar is initially slow, very good growth with profuse sporulation is observed on this medium after 14 d. Very good growth occurs on yeast extract-malt extract agar. Good growth is observed on oatmeal agar and moderate growth on Czapek's solution agar (Atlas, 1993). Growth on glycerol-asparagine agar is poor. The substrate mycelium is blue on yeast extract-malt extract agar and oatmeal agar, but light gray on Czapek and glycerol-asparagine media. Degrades casein, DNA, gelatin, guanine, hypoxanthine, starch (weakly), Tween 80, L-tyrosine, xanthine, and xylan but not adenine, allantoin, or urea. Uses L(+)-arabinose, D(+)-cellobiose, D(−)-fructose, D(+)-galactose, glycerol, *myo*-inositol, lactose, maltose, D-mannitol, D(+)-mannose, L(+)-rhamnose, D(−)-ribose, sodium acetate, sodium butyrate, sodium DL-malate, sodium malonate, sodium propionate, sodium pyruvate, sodium succinate, sucrose (weak growth), trehalose, and D(+)-xylose as sole carbon sources but not adonitol, *meso*-erythritol, inulin, D(+)-melezitose, D(+)-melibiose, methyl α-D-glucoside, raffinose, salicin, sodium benzoate, sodium citrate, sodium formate, sodium maleate, sodium oxalate, sodium salicylate, sodium L(+)-tartrate, L(−)-sorbose, or xylitol. Tests for nitrate reductase and the production of H_2S are positive, but pectin is not hydrolyzed. Lipase and lecithinase are produced on egg-yolk agar, but protease activity is not seen on this medium after the recommended 2 d of incubation (there is weak activity after 6 d). The cell wall contains LL-A_2pm (cell-wall type I). The whole-cell sugar pattern contains no diagnostic sugars. No antibiosis is exhibited against *Escherichia coli* ATCC 25922 or *Pseudomonas aeruginosa* ATCC 27853. Grows in the presence of (µg/ml unless stated otherwise): cefotaxime (100), cephaloridine (100), D-cycloserine (50), lincomycin (100), oleandomycin (100), penicillin G (10 IU/ml), phenol (0.1%), 2-phenylethanol (0.1%), sodium chloride (10%), and vancomycin (50) and at 45°C but not at 4°C, pH 4.3, or in the presence of sodium azide (0.01%), capreomycin (20), gentamicin (100), kanamycin (10), neomycin (50), rifampin (50), streptomycin (100), tobramycin (50), or viomycin (8). Uses DL-α-amino-*n*-butyric acid, 4-amino-*n*-butyric acid, L-arginine, DL-citrulline, L-cysteine,

L-histidine, L-methionine, DL-ornithine, potassium nitrate, L-serine, L-threonine, and L-valine as sole nitrogen sources, but not L-hydoxyproline or L-phenylalanine.

Type strain shows the highest sequence similarity to: *S. iakyrus*, AB184877, 99.3%; *S. longispororuber*, AB184440, 99.1%; *S. griseoflavus*, AJ781322, 99%; *S. viridodiastaticus*, AY999852, 99%; *S. lusitanus*, AB184424, 99%; *S. griseorubens*, AB184139, 99%.

Source: type strain was isolated from Cape Town, the Cape of Good Hope, South Africa.

DNA G+C content (mol%): 73.4.

Type strain: PK-Blue, ATCC BAA-411, CIP 108060, DSM 41797, JCM 12682, KCTC 9973, NRRL B-24240.

Sequence accession no. (16S rRNA gene): AF452714.

449. **Streptomyces speleomycini** Preobrazhenskaya and Szabó 1986, 575[VP] (Effective publication: Preobrazhenskaya and Szabó *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

spe.le.o.my.ci′ni. N.L. n. *speleomycinum* speleomycin; N.L. gen. n. *speleomycini* of speleomycin, intended to mean spelomycin producing.

Spore chains are straight (*Rectiflexibiles*); spores are smooth. On mineral agar 1: aerial mycelium is light yellowish creamy, yellow; substrate mycelium is reddish gray brownish; no diffusible pigment. On glycerol-nitrate agar, oatmeal agar, glucose-nitrate agar, glycerol-asparagine agar: aerial mycelium is mealy, whitish yellow, light yellow, yellow; substrate mycelium is colorless; no diffusible pigment. On starch-ammonia agar, starch agar (Waksman, 1961): aerial mycelium is whitish, light yellow; substrate mycelium is colorless to gray, olive gray; no diffusible pigment. On organic agar 2: aerial mycelium is whitish; substrate mycelium is gray brownish yellow; no diffusible pigment. Melanoid pigments are not formed. Growth on ribose, fructose, xylose, and galactose; no growth on rhamnose, arabinose, or inositol. Antibiotic: speleomycin.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: B-23.

Sequence accession no. (16S rRNA gene): no sequence available.

Further comments: strain B-23 was first described as *Actinomyces erythreus* subsp. *speleomycini* Szabó and Preobrazhenskaya 1962.

450. **Streptomyces spheroides** (Baldacci 1944) Wallick, Harris, Reagan, Ruger and Woodruff 1956, 911[AL] (*Actinomyces caeruleus* Baldacci 1944, 180; *Streptomyces caeruleus* Pridham, Hesseltine and Benedict 1958, 60 emend. Lanoot, Vancanneyt, Cleenwerck,Wang, Li, Liu and Swings 2002, 828)

sphe.ro.i′des. Gr. n. *sphaira* a ball, a sphere; Gr. adj. suff. *eides* similar; N.L. masc. adj. *spheroides* similar to a ball referring to the characteristic compact coils of spores, resembling spheres.

Spore chains in Section *Spirales*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to pale yellow or light yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, sucrose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Only traces of growth are found on iso-inositol and raffinose. A trace of growth also occurs on the carbon-free basal medium.

For sequence similarity, see type strain of *Streptomyces caeruleus*.

Type strain: ATCC 23965, CBS 491.62, CBS 948.68, BCRC 11559, DSM 40292, NBRC 12917, JCM 4252, JCM 4670, LMG 19392, NCIMB 11891, NRRL 2449, NRRL-ISP 5292, RIA 1200, RIA 700.

Sequence accession no. (16S rRNA gene): EF178698.

Further comments: Streptomyces spheroides Wallick et al. 1956 is a later heterotypic synonym of *Streptomyces caeruleus* (Baldacci 1944) Pridham et al. 1958 emend. Lanoot et al. 2002.

451. **Streptomyces spinoverrucosus** Diab and Al-Gounaim 1982, 331[VP]

spi.no.ver.ru.co′sus. L. adj. *spinosus* thorny; L. adj. *verrucosus* warty; N.L. masc. adj. *spinoverrucosus* spiny and warty, referring to the spiny and warty spore surface.

Spore chains are in the form of terminal, closed, or compact spirals with two or more turns. There are 10 to 20 or more spores per chain. Spore surfaces are spiny; some spores have spiny and warty surfaces. Mature aerial mass colors in the green color series on salts starch agar, yeast malt agar, oatmeal agar, and glycerol-asparagine agar (Tresner–Backus color series tabs) were matched to the red, yellow, green, and gray color wheels. T.G. Pridham (who confirmed the color series) stated that strain 163MA represents a good example of the problem involved in use of color as a major criterion in characterization and classification of streptomycetes and streptoverticillia. The reverse sides of the colonies are colorless or faint yellow on salts starch agar and brownish red on yeast malt agar, oatmeal agar, and glycerol asparagine agar. The red color is pH-sensitive.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone yeast broth. The water-soluble pigments produced are brown on yeast malt agar and glycerol-asparagine agar and red or reddish brown on oatmeal agar. An orange water-soluble pigment may be formed in salts-starch agar.

D-Glucose, D-xylose, L-arabinose, iso-inositol, D-mannitol, fructose, rhamnose, sucrose, and raffinose were utilized for growth. Growth on Czapek's solution was good.

A whole-cell hydrolysate analysis revealed the presence of LL-A_2pm.

Type strain shows the highest sequence similarity to: *S. lusitanus*, AB184424, 99.2%; *S. levis*, AB184670, 99.1%; *S. bellus*, AB184849, 99.1%; *S. coerulescens*, AY999720, 99.1%; *S. coeruleorubidus*, AY999719, 99%; *S. carpinensis*, AB184574, 99%; *S. parvulus*, AB184326, 99%; *S. gancidicus*, AB184660, 99%; *S. lomondensis*, AB184673, 99%.

Type strain: Diab 163MA, NCIB (now NCIMB) 11666, ATCC 33692, DSM 41648, NBRC 14228, NBRC 14250, JCM 5077, NRRL B-16932.

Sequence accession no. (16S rRNA gene): AB184578.

452. **Streptomyces spiralis** (Falcão de Morais 1970) Goodfellow, Williams and Alderson 1986a, 575[VP] (Effective publication: Goodfellow, Williams and Alderson 1986a, 50.) (*Elytrosporangium spirale* Falcão de Morais 1970, 79)

spi.ra′lis. L. n. *spira* a spiral; N.L. masc. adj. *spiralis* spiraled, referring to spiral spore chains.

Forms extensively branched substrate and aerial mycelium. The latter bears long spirals spore chains and the former occasional chains of spores. The spore surface is smooth. The aerial spore mass is yellowish gray; the reverse color is cream to yellow. Does not form melanin pigments. Adenine, esculin, casein, guanine, hypoxanthine, pectin, starch, testosterone, and tyrosine are degraded but allantoin, arbutin, chitin, elastin, lecithin, urea, and xanthine are not. Hydrogen sulfide is produced but nitrate is not reduced. L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, inulin, D-lactose, mannitol, D-mannose, melibiose, raffinose, L-rhamnose, salicin, sucrose, trehalose, and xylitol are used as sole carbon sources but adonitol, melezitose, and D-xylose are not. Grows on L-arginine, L-cysteine, L-histidine, potassium nitrate, L-serine, L-threonine, and L-valine, but not on DL-amino-n-butyric acid, L-hydroxyproline, L-methionine, or L-phenylalanine, as sole nitrogen source. Growth occurs at 37 and 45°C but not at 10°C. Tolerant to phenol (0.1%, w/v), sodium azide (0.02%, w/v), and sodium chloride (7%, w/v). Resistant to rifampin but sensitive to sodium chloride at 10% (w/v). Does not show antimicrobial activity against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046^T, *Saccharomyces cerevisiae* CBS 1171^T, or *Streptomyces murinus* ISP 5091. Contains octahydrogenated menaquinones with nine isoprene units as the predominant isoprenolog.

Type strain shows the highest sequence similarity to: *S. ruber*, AB184604, 99%; *S. fumigatiscleroticus*, DQ442499, 99%.

Source: isolated from soil, Brazil.

DNA G+C content (mol%): not known.

Type strain: ATCC 25664, DSM 43836, NBRC 14215, KCC A-0302, JCM 3302, NRRL B-16922, VKM Ac-1311.

Sequence accession no. (16S rRNA gene): EF178683.

453. **Streptomyces spiroverticillatus** Shinobu 1958, 93[AL]

spi.ro.ver.ti.cil.la′tus. L. n. *spira* a coil, spiral; L. n. *verticillus* a whorl; N.L. adj. *verticillatus* whorled; N.L. masc. adj. *spiroverticillatus* coiled and whorled.

Spore chains in Section *Retinaculiaperti*. Shinobu's original description makes note of verticils or whorls "near the base of the aerial mycelium". Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth. Conidia-like fragments in substrate mycelium (one observer); sclerotia (two observers).

Color of colony: aerial mass color in the White color series on yeast-malt agar and glycerol-asparagine agar; White or Red series on oatmeal agar and salts-starch agar. Reverse side of colony is grayed yellow to yellow-brown is modified by red or orange on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed slightly from yellow-brown to reddish brown with the addition of 0.05 M NaOH and from reddish-brown to yellow-brown with 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar and tyrosine agar. Pigments other than traces of yellow are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer reports a trace of yellow pigment that may change to pink with addition of 0.05 M NaOH.

D-Glucose, L-arabinose. D-xylose, and D-fructose are utilized for growth. No growth or only trace of growth on iso-inositol, D-mannitol, rhamnose, and raffinose. Variable reports on growth with sucrose.

Type strain shows the highest sequence similarity to: *S. cremeus*, AB184124, 99.7%; *S. albolongus*, AB184425, 99.4%; *S. celluloflavus*, AB184476, 99.4%; *S. griseobrunneus*, AB249912, 99.4%; *S. candidus*, DQ026663, 99.3%; *S. cavourensis* subsp. *cavourensis*, DQ445791, 99.3%; *S. praecox*, AB184293, 99.2%; *S. fulvorobeus*, AB184711, 99.2%; *S. lipmanii*, AB184148, 99.2%; *S. fimicarius*, AY999784, 99.2%; *S. flavovirens*, DQ026635, 99.2%; *S. anulatus*, DQ026637, 99.2%; *S. flavofuscus*, AB249935, 99.2%; *S. microflavus*, DQ445795, 99.2%; *S. alboviridis*, AB184256, 99.2%; *S. pluricolorescens*, DQ442540, 99.1%; *S. albovinaceus*, AB249958, 99.1%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.1%; *S. argenteolus*, AB045872, 99.1%; *S. griseolus*, AB184768, 99.1%; *S. mediolani*, AB184674, 99.1%; *S. luridiscabiei*, AF361784, 99.1%; *S. acrimycini*, AY999889, 99.1%; *S. californicus*, AB184755, 99.1%; *S. flavogriseus*, AJ494864, 99.1%; *S. baarnensis*, EF178688, 99.1%; *S. badius*, AY999783, 99.1%; *S. rubiginosohelvolus*, AB184240, 99.1%; *S. floridae*, AB184656, 99.1%; *S. globisporus* subsp. *globisporus*, EF178686, 99.1%; *S. griseinus*, AB184205, 99.1%; *S. sindenensis*, AB184759, 99.1%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.1%; *S. griseoplanus*, AY999894, 99.1%; *S. pulveraceus*, AB184806, 99%; *S. parvus*, DQ442537, 99%; *S. cyaneofuscatus*, AB184860, 99%; *S. cinereorectus*, AB184646, 99%; *S. halstedii*, EF178695, 99%.

454. **Streptomyces spitsbergensis** Wieczorek, Mordarska, Zakrzewska-Czerwinska, Gamian and Mordarski 1993, 86[VP]

spits.ber.gen′sis. N.L. masc. adj. *spitsbergensis* of or belonging to Spitsbergen, the source of the soil sample from which the type strain was isolated.

Spore chains are *Rectiflexibiles*. Spore surface is smooth. Color of branching substrate mycelium ranges from red to reddish brown, depending on the growth medium. Aerial mycelium is pink to violet. Soluble pigments (including melanin) are not produced. Hydrolyzes gelatin and starch. Nitrate is not reduced. Grows well at 25–37°C; no growth occurs at 45°C. Type I cell wall and type PII phospholipid pattern (saturated iso and anteiso fatty acids, lack of mycolic acids and major glycolipids). The species produces some prodiginine-like metabolites with immunosuppressive activity.

For sequence similarity, see type strain of *Streptomyces hiroshimensis*.

Source: the type strain was isolated from soil from Spitsbergen.

DNA G+C content (mol%): 71.0.

Type strain: S-2, ATCC 51269, NBRC 15745, JCM 8881, PCM 2404.

Sequence accession no. (16S rRNA gene): AB184700.

Further comments: Hatano et al. (1997) propose *Streptomyces spitsbergensis* Wieczorek et al. 1993 as a later heterotypic synonym of *Streptomyces baldaccii* corrig. (Farina and Locci 1966) Witt and Stackebrandt 1991.

According to Hatano et al. (2003), *Streptomyces spitsbergensis* Wieczorek et al. 1993 is a later heterotypic synonym of *Streptomyces hiroshimensis* (Shinobu 1955) Witt and Stackebrandt 1991.

455. **Streptomyces sporocinereus** (*ex* Krasil'nikov 1970b) Preobrazhenskaya 1986, 575[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces sporocinereus*" Krasil'nikov 1970b)

spo.ro.ci.ne′re.us. Gr. n. *spora* seed; L. adj. *cinereus* ash-colored; N.L. masc. adj. *sporocinereus* ash-colored spores.

Spore chains are spiral (*Spirales*); spores are warty. On mineral agar 1 and oatmeal agar: aerial mycelium is gray, dark gray, black; substrate mycelium is colorless; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is white or beige; substrate mycelium colorless; no diffusible pigment. On starch-ammonia agar: aerial mycelium is gray; substrate mycelium is colorless to yellowish beige; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is gray; substrate mycelium colorless; no diffusible pigment. On organic agar 2: aerial mycelium is gray; substrate mycelium and diffusible pigment are yellow-brown, brown. Melanoid pigments are not formed. Utilization of glucose, galactose, and starch; no digestion of fructose.

Type strain shows the highest sequence similarity to: *S. endus*, AY999911, 100%; *S. hygroscopius* subsp. *hygroscopius*, AB184428, 100%; *S. demainii*, DQ334782, 99.9%; *S. yogyakartensis*, AB249942, 99.5%; *S. violaceusniger*, AJ391823, 99.5%; *S. albiflaviniger*, AJ391812, 99.3%.

Source: not known.

Type strain: ATCC 43692, DSM 41460, INMI 32, JCM 9093, NBRC 100766, NRRL B-16376, VKM Ac-312.

Sequence accession no. (16S rRNA gene): AB249933.

456. **Streptomyces sporoclivatus** (*ex* Krasil'nikov 1970b) Preobrazhenskaya 1986, 575[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces sporoclivatus*" Krasil'nikov 1970b).

Etymology is not provided.

Spore chains are spiral (*Spirales*); spores are warty. On mineral agar 1, oatmeal agar, starch-ammonia agar: aerial mycelium is whitish gray or gray; substrate mycelium is colorless; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is white or light yellow; substrate mycelium is dark yellow; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is white, light gray; substrate mycelium is colorless to yellow; no diffusible pigment. On organic agar 2: aerial mycelium is white; substrate mycelium is yellow; no diffusible pigment. Melanoid pigments are not formed. Grows on glucose, fructose, xylose, galactose, raffinose, and mannitol; no growth on rhamnose or arabinose.

Type strain shows the highest sequence similarity to: *S. antimycoticus*, AB184185, 100%; *S. geldanamycininus*, DQ334781, 99.8%; *S. rutgersensis* subsp. *castelarensis*, AY508511, 99.8%; *S. melanosporofaciens*, AJ271887, 99.6%; *S. rhizosphaericus*, AB249941, 99.1%; *S. asiaticus*, AB249947, 99.1%.

Sequence accession no. (16S rRNA gene): DQ442544.

459. **Streptomyces stelliscabiei** Bouchek-Mechiche, Gardan, Normand and Jouan 2000, 98[VP]

stel.li.sca'bi.ei. L. n. *stella -ae* a star; L. n. *scabies -ei* mange; N.L. gen. n. *stelliscabei* referring to lesions from which these strains were isolated, which looks like stars.

Spores are gray and are borne in mature spiral chains. Melanin is produced on tyrosine agar. L-Arabinose, D-fructose, D-glucose, D-mannitol, inositol, raffinose, rhamnose, sucrose, and D-xylose are utilized for growth. Most strains studied degrade xanthine. All strains are susceptible to 20 µg/ml streptomycin, 0.5 µg/ml crystal violet, 100 µg/ml oleandomycin, and 5% (w/v) NaCl, but not to 25 µg/ml oleandomycin or 10 IU/ml penicillin G. Utilizes *trans*-aconitate, D(+)trehalose, and α-D(+)melibiose but do not assimilate 5-keto-D-gluconate, ONPG, betaine, mucate, D-saccharate, DL-lactate, gentisate, or turanose.

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. europaeiscabiei* DSM 41802[T], 47%; *S. reticuliscabiei* DSM 41804[T], 20%.

DNA G+C content (mol%): 71.7.

Type strain: CFBP 4521, CIP 107060, CIP 107126, DSM 41803, ICMP 13715, NCPPB 4040.

Sequence accession no. (16S rRNA gene): AJ007429.

460. **Streptomyces stramineus** Labeda, Lechevalier and Testa 1997, 752[VP]

stra.mi'ne.us. L. masc. adj. *stramineus* made of straw, of straw, intended to mean straw colored, referring to the color of the aerial mycelium and spore mass.

Aerial mycelium forms verticils on which umbels consisting of straight chains of ovoid, smooth surface, straw yellow spores (0.5 × 1.0 µm) are produced. The substrate mycelium is yellow to yellowish brown. Soluble pigments that range from yellowish to shades of brown are produced on several media, such as yeast extract-malt extract. Casein, esculin, gelatin, hypoxanthine, starch, tyrosine, and xanthine are hydrolyzed; adenine and urea are not hydrolyzed. Phosphatase is produced; nitrate is not reduced. Melanin pigments are not produced from tyrosine. Growth occurs in the presence of glycerol, 5% NaCl, and lysozyme; no growth occurs in the presence of salicylate. Acetate, citrate, malate, propionate, pyruvate, and succinate are assimilated; benzoate, lactate, mucate, oxalate, and tartrate are not assimilated. Acid is produced from adonitol, dextrin, fructose, glucose, glycerol, inositol, maltose, mannitol, mannose, sorbitol, and trehalose; no acid is produced from arabinose, cellobiose, dulcitol, erythritol, galactose, melibiose, methyl α-D-glucoside, raffinose, rhamnose, salicin, sucrose, xylose, or methyl β-D-xyloside. Growth occurs on fructose, glucose, inositol, and mannitol as the sole carbon source but not on galactose, raffinose, rhamnose, salicin, or xylose. Growth occurs at 10 and 42°C, but not 52°C. Produces the antibiotics LL-BO1208α and LL-BO1208β.

Type strain shows the highest sequence similarity to: *S. eurocidicus*, AY999790, 99.2%; *S. netropsis*, AB184848, 99.2%; *S. albireticuli*, AB184881, 99.1%.

Source: isolated from a grassland soil sample from South Dakota.

DNA G+C content (mol%): 75.0.

Type strain: CIP 105398, DSM 41783, NBRC 16131, JCM 10649, NRRL 12292.

Sequence accession no. (16S rRNA gene): AB184720.

461. **Streptomyces subrutilus** Arai, Kuroda, Yamagishi and Katoh 1964, 25[AL]

sub.ru′ti.lus. L. masc. adj. *subrutilus* reddish.

Spore chains in Section *Rectiflexibiles*. Long, straight, or slightly flexuous spore chains often contain more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (4ec, 5ec, 6ec, 5cb, grayish yellowish pink) on yeast-malt agar, oatmeal agar, and salts-starch agar; Red or White color series on glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (moderate orange yellow or moderate orange brown on yeast-malt agar; pale yellow or grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth but are formed only weakly or not at all in tyrosine agar. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and D-fructose are utilized for growth. Reports vary on utilization of sucrose and D-mannitol, but growth is not abundant on these media. No growth or only traces of growth with L-arabinose, D-xylose, iso-inositol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. nojiriensis*, AJ781355, 99.7%; *S. spororaveus*, AJ781370, 99.7%; *S. avidinii*, AB184395, 99.7%; *S. xanthophaeus*, DQ442560, 99.6%; *S. vinaceus*, AB184394, 99.5%; *S. goshikiensis*, EF178693, 99.5%; *S. cirratus*, AY999794, 99.5%; *S. cinnamonensis*, AB184707, 99.4%; *S. sporoverrucosus*, DQ442544, 99.3%; *S. virginiae*, D85119, 99.3%; *S. colombiensis*, DQ026646, 99.3%.

Type strain: ATCC 27467, CBS 689.72, BCRC 11921, DSM 40445, IFM 1222, NBRC 13388, JCM 4695, JCM 4834, KCTC 9045, NRRL B-12377, NRRL-ISP 5445, RIA 1349, VKM Ac-1210.

Sequence accession no. (16S rRNA gene): X80825.

462. **Streptomyces sulfonofaciens** Miyadoh, Shomura, Ito and Niida 1983, 323[VP]

sul.fon.o.fa′ci.ens N.L. n. *acidum sulfonicum* sulfonic acid; L. part. adj. *faciens* producing; N.L. part. adj. *sulfonofaciens* producing sulfonic acid.

Spores are 0.7–0.8 × 1.0–1.5 μm and oval or cylindrical; Spore surface is smooth. Spore chains are nearly straight and moderately short, bearing 10–30 spores. Fragmentation of mycelium is not observed on agar or in liquid cultures. Neither sclerotia nor sporangia are formed. Colors of the mature aerial masses produced on inorganic salts-starch agar, oatmeal agar, and yeast extract-malt extract agar belong to the Red color series (5cb, grayish yellowish pink). Undersides of colonies are colorless to pale yellowish brown. No diffusible pigments are formed, except for a light rose beige pigment formed on inorganic salts-starch agar. Frequent subculturing of strain SF-2130[T] onto fresh agar media results in the loss of the ability to produce aerial mycelium, and small aerial mycelium tends to be formed and then lysed. Positive physiological properties include gelatin liquefaction, starch hydrolysis, and milk peptonization. Negative properties include production of melanoid pigment on peptone-yeast extract-iron agar and tryptone-yeast extract broth, milk coagulation, and nitrate reduction. On ISP 9 medium, good or moderate growth is obtained with D-glucose, L-arabinose, D-xylose, L-rhamnose, and D-fructose, and poor growth is obtained with D-mannitol and sucrose. No growth is observed with iso-inositol or raffinose. The temperature range for growth is 15–42°C. Optimum growth occurs between 27 and 33°C. Cell Analysis of the cell-wall hydrolysates by paper chromatography demonstrates the presence of LL-A_2pm in addition to glycine. Thus, strain SF-2130[T] can be considered to have cell-wall type I. Produces a new β-lactam antibiotic.

Type strain shows no sequence similarity over 99%.

Source: soil.

DNA G+C content (mol%): not known.

Type strain: SF-2103, ATCC 31892, DSM 41679, NBRC 14260, JCM 5069, NRRL B-16438.

Sequence accession no. (16S rRNA gene): AB249974.

463. **Streptomyces sulphureus** (Gasperini 1894) Waksman *in* Waksman and Lechevalier 1961, 278[AL] ("*Actinomyces sulphureus*" Gasperini 1894, 78; "*Streptothrix sulphurea*" Caminiti 1907, 197; "*Nocardia sulfurea*" Vuillemin 1931, 129)

sul.phu′re.us. L. masc. adj. *sulphureus* of sulfur, sulphurous, referring to the bright sulfur-yellow color of the aerial mycelium.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Short, crooked chains form irregular and imperfect spirals, hooks, or loops. These are not representative of the large hooks, loops, and primitive spirals seen in typical *Retinaculiaperti* cultures. This morphology is seen on yeast-malt agar and oatmeal agar and sometimes on glycerol-asparagine agar. Morphology may also be observed on carbon-utilization medium enriched with D-glucose. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series (1½fb, light yellow, or 1½db, pale greenish yellow) on yeast-malt agar and oatmeal agar and sometimes on salts-starch agar or glycerol-asparagine agar if adequate aerial mycelium is developed. Reverse side of colony with no distinctive pigments (yellowish brown to olive brown on yeast-malt agar; grayish yellow, grayish greenish yellow, or olive on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth or are formed very weakly in peptone-yeast-iron agar and tryptone-yeast broth. No pigment is usually found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar, but one of three observers reports a pale violet pigment in oatmeal agar in 14 d. This pigment becomes pale yellowish brown with the addition of 0.05 M HCl.

Growth is poor on carbon-utilization medium enriched with D-glucose. Comparison with growth on D-glucose suggests equal or better utilization of L-arabinose, D-xylose, D-mannitol, D-fructose, and rhamnose, but utilization of all carbon sources should be verified on a basal medium supporting better growth. Sucrose apparently is not utilized, and reports vary on the utilization of raffinose and iso-inositol.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27468, CBS 646.72, BCRC 13764, DSM 40104, HUT 6080, NBRC 13345, IMET 40623, JCM 4085, JCM 4835, LMG 19355, NRRL B-1627, NRRL B-2195, NRRL-ISP 5104, RIA 1306, VKM Ac-1820.

Sequence accession no. (16S rRNA gene): DQ442546.

464. **Streptomyces synnematoformans** Hozzein and Goodfellow 2007, 2012[VP]

syn.ne.ma.to.for′mans. Gr. prep. *syn* in company with, together with; Gr. n. *nema* thread; N. Gr. n. *synnema* threads wrapping together; L. part. adj. *formans* forming; N.L. part. adj. *synnematoformans* synnemata-forming, referring to the ability of the organism to form synnemata.

Non-acid–alcohol-fast actinomycete; forms extensively branched substrate mycelium that carries aerial hyphae which differentiate into short straight to flexuous chains of smooth-surfaced spores. Forms synnemata-like structures but not sclerotia. Grayish to blackish red aerial spore mass and a dark red to reddish black substrate mycelium are formed on synthetic agar media. Deep grayish red diffusible pigment is produced on inorganic salts-starch agar. Does not hydrolyze arbutin or degrade adenine or uric acid. Cellobiose, D-fructose, D-galactose, D-glucose, maltose, D-mannose, and trehalose are used as sole carbon sources for energy and growth, but not L-arabitol, *meso*-erythritol, melezitose, D-salicin, D-sorbitol, or D-xylitol (all at 1%, w/v). Similarly, pyruvate is used as a sole carbon source, but not acetate, malonate, or succinate (all at 0.1%, w/v). Grows from 10°C to 37°C and from pH 6.5 to 9.5. Grows in the presence of 7% (w/v) sodium chloride.

Type strain shows no sequence similarity over 99%.

Source: the type strain was isolated from a sand dune soil collected at Borg El-Arab in Egypt.

DNA G+C content (mol%): not known.

Type strain: S155, CGMCC 4.2055, DSM 41902.

Sequence accession no. (16S rRNA gene): EF121313.

465. **Streptomyces syringium** (Konev 1986) Witt and Stackebrandt 1996, 836[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) [*Streptoverticillium syringium* (*ex* Konev, Barashkova and Shenin 1974) Konev 1986].

Etymology is not known.

Spore chains in Section *Rectiflexibiles*. Spores are longish with a smooth surface, 0.5–0.6 × 0.8–1.4 µm in size. Aerial mycelium is well developed, white to light pink and violet color. Substrate mycelium is of a brown color. Soluble pigment is brown-greyish. No tyrosine or H_2S production. Utilizes D-glucose, rhamnose, D-fructose, and iso-inositol, but not lactate, sucrose, or raffinose. Weak growth on L-arabinose, D-xylose, and D-mannitol. Antagonistic against Gram-positive bacteria and fungi. Produces polyene.

For sequence similarity, see type strain of *Streptomyces netropsis.*

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 41480, DSM 41502, NBRC 15900, JCM 9948, LIA 0725, VKM Ac-1230.

Sequence accession no. (16S rRNA gene): AJ781375.

Further comments: this species was inadvertently omitted from Validation List no. 38 (Int. J. Syst. Bacteriol. 1991, 41, 456–457); the effective date of validation is that of list no. 38 (July 1991).

According to Hatano et al. (2003), *Streptomyces syringium* (Konev 1986) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces netropsis* (Finlay et al. 1951) Witt and Stackebrandt 1991.

466. **Streptomyces tanashiensis** Hata, Ohki and Higuchi 1952, 529[AL]

ta.na.shi.en′sis. N.L. masc. adj. *tanashiensis* of or belonging to Tanashi-machi, a town near Tokyo, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Rectiflexibiles.* Mature spore chains generally have 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (pale yellow to light olive brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not on tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. Reports vary on utilization of D-fructose. Only traces of growth are found with sucrose, iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. nashvillensis*, AB184286, 100%; *S. violaceorectus*, AB184314, 99.2%; *S. showdoensis*, AB184389, 99.1%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99.1%; *S. roseoviridis*, AB184239, 99.1%; *S. racemochromogenes*, DQ026656, 99.1%; *S. viridobrunneus*, AJ781372, 99.1%; *S. roseolus*, AB184168, 99.1%; *S. polychromogenes*, AB184292, 99.1%; *S. bikiniensis*, X79851, 99.1%; *S. vietnamensis*, DQ311081, 99%; *S. flavotricini*, AB184132, 99%.

Source: isolated from soil from Tanashi-machi, a town near Tokyo, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 23967, CBS 165.64, CBS 950.68, BCRC 12641, DSM 40195, HUT 6070, NBRC 12919, IMET 42939, JCM 4086, JCM 4671, NRRL B-1692, NRRL-ISP 5195, RIA 1148, VKM Ac-1892.

Sequence accession no. (16S rRNA gene): AJ781362.

467. **Streptomyces tauricus** (*ex* Ivanitskaya, Upiter, Sveshnikova and Gause 1966) Sveshnikova 1986, 575[VP] (Effective publication: Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces tauricus*" Ivanitskaya, Upiter, Sveshnikova and Gause 1966; "*Streptomyces tauricus*" Pridham 1970)

tau′ri.cus. L. masc. adj. *tauricus* of or belonging to the Taurians (a Thracian people, living in what is now Crimea), Albanian.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Terminal spirals of several turns and some hooks or loops are found on long spore chains of 10–50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5cb or 6ec, grayish yellowish pink; 5ca, light yellowish pink; 3ca, pale orange yellow; or 7ca, light yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with distinctive red pigments. Grayish red, reddish brown, or yellowish pink on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator, changing from orange or red to blue or violet with the addition of 0.05 M NaOH and from brownish red to yellowish red with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth but weakly or not at all in tyrosine agar. Red (pink) pigment is sometimes found in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. When pigment is present in the medium it is pH-sensitive, showing the same changes observed with the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. glomeroaurantiacus*, AB249983, 99.1%; *S. aurantiacus*, AJ781383, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27470, CBS 757.72, BCRC 12822, DSM 40560, NBRC 13456, IMET 43541, INA 8173, JCM 4837, NRRL B-12497, NRRL-ISP 5560, RIA 1417, VKM Ac-1853.

Sequence accession no. (16S rRNA gene): AB045879.

468. **Streptomyces tendae** Ettlinger, Corbaz and Hütter 1958a, 351[AL]

ten′da.e. N.L. gen. n. *tendae* of Tende, Germany, the source of the soil from which the organism was isolated.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Straight to flexuous spore chains are most common on yeast-malt agar and spirals are best developed on salts-starch agar. Straight, flexuous, *Retinaculiaperti*, and spiral spore chains are recorded for oatmeal agar and glycerol-asparagine agar. Mature spore chains generally have 10–50 spores per chain, longer chains are sometimes observed. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony is yellow or greenish yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is changed from yellow to orange by addition of 0.05 M HCl.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast extract broth. Yellow pigment found in medium in glycerol-asparagine agar; traces of yellow pigment may also diffuse into yeast-malt agar, oatmeal agar, and salts-starch agar. The yellow pigment is changed to yellowish orange or orange by 0.05 M HCl.

D-Glucose, L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on raffinose.

Type strain shows the highest sequence similarity to: *S. violaceorubidus*, AJ781374, 99.8%; *S. violaceoruber*, AF503492, 99.6%; *S. coelescens*, AF503496, 99.6%; *S. rubrogriseus*, AB184681, 99.6%; *S. anthocyanicus*, AB184631, 99.5%; *S. humiferus*, AF503491, 99.5%; *S. violaceolatus* AF503497, 99.5%; *S. lienomycini*, AJ781353, 99.5%; *S. tricolor*, AB184687, 99.4%; *S. matensis*, AB184221, 99.2%; *S. griseorubens*, AB184139, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. geysiriensis*, DQ442501, 99.1%; *S. minutiscleroticus*, EF178696, 99.1%; *S. ghanaensis*, AY999851, 99%; *S. rochei*, AB184237, 99%; *S. eurythermus*, D63870, 99%; *S. parvulus*, AB184326, 99%; *S. malachitospinus*, AB249954, 99%; *S. plicatus*, AB184291, 99%; *S. vinaceusdrappus*, AY999929, 99%.

Source: isolated from soil from Tende, Germany.

DNA G+C content (mol%): not known.

Type strain: AS 4.1460, ATCC 19812, CBS 565.68, BCRC 12167, DSM 40101, IFM 1176, NBRC 12822, IMET 40459, JCM 4149, JCM 4610, LMG 5987, LMG 19314, NCIMB 9614, NRRL B-2313, NRRL-ISP 5101, RIA 1092, RIA 534, UNIQEM 199, VKM Ac-1889.

Sequence accession no. (16S rRNA gene): D63873.

469. **Streptomyces termitum** Duché, Heim and Laboureur *in* Heim 1951, 359[AL]

ter.mi′tum. L. n. *termes -itis* woodworm, termite; L. gen. pl. n. *termitum* of termites, referring to the source of the organism.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally long and flexuous with 10–50 or often more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (3ca, pale orange-yellow to 5cb, grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless to pale or grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and D-xylose are utilized for growth. Utilization of D-fructose is doubtful. Reports vary on utilization of sucrose and rhamnose (two of three observers find no growth on these two carbon sources). No growth or only trace of growth with L-arabinose, iso-inositol, D-mannitol, and raffinose.

Type strain shows no sequence similarity over 99%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB184302.

470. **Streptomyces thermoalcalitolerans** Kim, Sahin, Minnikin, Zakrzewska-Czerwinska, Mordarski and Goodfellow 1999, 15[VP]

ther.mo.al.ca.li.to′le.rans. Gr. n. *therme* heat; N.L. n. *alcali* (from Arabic article *al* the; Arabic n. *qaliy* ashes of saltwort) alkali; L. part. adj. *tolerans* tolerating, enduring; N.L. part. adj. *thermoalcalitolerans* thermophilic alkali-tolerating.

Spiral chains of warty surfaced spores are borne on aerial hyphae. Forms extensively branched substrate and aerial hyphae. The aerial spore mass is gray; neither distinctive substrate mycelium colors nor diffusible pigments are formed. Melanin pigments are not produced on peptone-iron agar. Casein, DNA, gelatin, starch, testosterone, L-tyrosine, and xylan are degraded, but not adenine, arbutin, elastin, guanine, hypoxanthine, or xanthine. Adonitol, L-arabinose, arabitol, cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, α-lactose, D-mannitol, D-mannose, melezitose hydrate, melibiose, α-L-rhamnose, D-ribose, D-sorbitol, sucrose, trehalose, D-turanose, xylitol, and D-xylose are used as sole carbon sources for energy and growth, but D-raffinose is not. Growth occurs between 25 and 55°C, from pH 6.0 to 11.5 and in the presence of ampicillin (8 μg/ml), bacitracin (16 μg/ml), oleandomycin phosphate (16 μg/ml), penicillin G (15 international units), rifampin (16 μg/ml), streptomycin sulfate (4 μg/ml), tetracycline hydrochloride (16 μg/ml), and tunicamycin (10 μg/ml). In contrast, growth is inhibited in the presence of gentamicin sulfate (8 μg/ml), lincomycin hydrochloride (32 μg/ml), neomycin sulfate (8 μg/ml), novobiocin (4 μg/ml), oleandomycin phosphate (32 μg/ml), polymyxin B phosphate (32 μg/ml), rifampin (32 μg/ml), streptomycin sulfate (16 μg/ml), tetracycline hydrochloride (32 μg/ml), tobramycin sulfate (32 μg/ml), and vancomycin hydrochloride (16 μg/ml).

Type strain shows no sequence similarity over 99%.

Source: isolated from tropical garden soil collected by M. Goodfellow in 1991 from Yogyakarta, Central Java, Indonesia.

DNA G+C content (mol%): 73.0.

Type strain: TA56, DSM 41741, NBRC 16322, JCM 10673.

Sequence accession no. (16S rRNA gene): AB249909.

471. **Streptomyces thermoautotrophicus** Gadkari, Schricker, Acker, Kroppenstedt and Meyer 1991, 456[VP] (Effective publication: Gadkari, Schricker, Acker, Kroppenstedt and Meyer 1990, 3733.)

ther.mo.au.to.tro′phi.cus. Gr. adj. *thermos* hot; Gr. pref. *autos* self; Gr. adj. *throphikos* nursing, tending or feeding; N.L. masc. adj. *thermoautothrophicus* heat-loving self-nourishing, referring to the ability to grow at high temperature at the expense of CO or H_2 plus CO_2.

Forms chains of two to eight oval spores produced in a sheath residing on the substrate and scanty whitish aerial mycelium. No endospores, synnemata, sporangia, or sclerotia are found. Forms relatively stable branching vegetative hyphae with a diameter of 0.2–0.5 μm. Possesses LL-A_2pm and ribose (cell-wall type I). Mycolic acids are absent. Predominant menaquinone is MK-9(H_4); small amounts of MK-9(H_6) also occur. Phopholipid pattern is composed of phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol, and phosphatidylinositol mannosides (phospholipid type 2). Iso- and anteiso-branched fatty acid patterns are found, with C_{17}, C_{17}, and C_{16} being the predominant fatty acids. Small amounts of cyclopropane fatty acids and traces of 2-hydroxy fatty acids are also present.

Source: not known.

DNA G+C content (mol%): 70.6.

Type strain: UBT1, DSM 41605.

Sequence accession no. (16S rRNA gene): no sequence available.

472. **Streptomyces thermocarboxydovorans** Kim, Falconer, Williams and Goodfellow 1998, 65[VP]

ther.mo.car.bo.xy.do.vo′rans. Gr. n. *therme* heat; N.L. n. *carboxydum* carbon monoxide; L. v. *voro* to eat greedily, devour; N.L. part. adj. *thermocarboxydovorans* thermophilic, carbon monoxide consuming.

Moderately thermophilic, facultatively chemolithotrophic actinomycete with extensively branched substrate and aerial mycelia. *Rectiflexibiles* chains of smooth-surfaced spores are borne on aerial hyphae. The aerial spore mass is gray; distinctive substrate mycelium colors are not produced. Diffusible pigments are not formed. Melanin pigments are not produced on peptone-iron agar. The organism oxidizes hydrogen and can use carbon monoxide as sole source of carbon for energy and growth. Arbutin, DNA, elastin, guanine, hypoxanthine, RNA, starch, L-tyrosine, and xanthine are degraded. Nitrate is reduced and hydrogen sulfide is produced. Neither allantoin nor urea are hydrolyzed. D-Fructose, D-lactose, sodium fumarate, and sodium pyruvate, but not adonitol or xylitol are used as sole carbon sources. L-Arginine, D-aminobutyric acid, L-cysteine, L-histidine, L-methionine, potassium nitrate, L-serine, L-threonine, and L-valine, but not L-hydroxyproline, are used as sole nitrogen sources. Positive activity is seen for chymotrypsin, cystine arylamidase, α-galactosidase and lipase but not for α-glucosidase (API ZYM). Similarly, *N*-acetyl-β-D-glucosamidase is produced but not β-D-cellobiosidase or β-D-xylosidase. Growth occurs between 20°C and 55°C and in the presence of adenine (0.5%, w/v), crystal violet (0.001%, w/v), phenyl ethanol (0.3%, w/v), potassium tellurite (0.001%, w/v), sodium azide (0.01%, w/v), chloramphenicol (2 μg/ml), chlortetracycline (4 μg/ml), gentamicin sulfate (1 μg/ml), novobiocin (0.5 μg/ml), oleandomycin phosphate (1 μg/ml), penicillin G (16 μg/ml), polymyxin B (32 μg/ml),

and tobramycin sulfate (1 μg/ml). In contrast, growth was inhibited in the presence of phenol (1%, w/v), sodium azide (0.02%, w/v), rifampin (0.5 μg/ml), and streptomycin sulfate (2 μg/ml).

Type strain shows the highest sequence similarity to: *S. thermospinosisporus*, AF333113, 99.1%.

Source: isolated from soil.

DNA G+C content (mol%): 74.7 ± 0.05.

Type strain: AT52, CIP 105544, DSM 44296, NBRC 16324, JCM 10367.

Sequence accession no. (16S rRNA gene): U94489.

473. **Streptomyces thermocarboxydus** Kim, Falconer, Williams and Goodfellow 1998, 66[VP]

ther.mo.car.bo′xy.dus. Gr. n. *therme* heat; N.L. n. *carboxydum* carbon monoxide; N.L. masc. adj. *carboxydus* pertaining to carbon monoxide.

Moderately thermophilic, facultatively chemolithotrophic actinomycete with extensively branched substrate and aerial mycelia. *Retinaculiaperti* chains of warty-surfaced spores are borne on aerial hyphae. Aerial spore mass is gray; distinctive substrate mycelium colors are not produced. Diffusible pigments are not formed. Melanin pigments are not produced on peptone-iron agar. Organism oxidizes hydrogen and can use carbon monoxide as a sole source of carbon for energy and growth. Esculin, arbutin, DNA, elastin, guanine, hypoxanthine, starch, testosterone, and xanthine are degraded. Nitrate is reduced and hydrogen sulfide is produced. Neither allantoin nor urea are hydrolyzed. D-Fructose, D-glucose, *myo*-inositol, D-lactose, mannitol, trehalose, and sodium propionate, but not adonitol, raffinose, sucrose, xylose, sodium acetate, sodium fumarate, or sodium pyruvate, are used as sole carbon sources. L-Arginine, D-aminobutyric acid, L-cysteine, L-histidine, potassium nitrate, L-serine, L-threonine, and L-valine, but not L-hydroxyproline or L-methionine, are used as sole nitrogen sources. Positive activity is seen for chymotrypsin, cystine arylamidase, α-glucosidase, lipase, and trypsin but not for α-galactosidase (API ZYM). *N*-Acetyl-β-D-galactosamidase, *N*-acetyl-β-D-glucosamidase, and α-L-arabinosidase are produced but not β-D-cellobiosidase, β-D-fucopyranosidase, α-D-mannosidase, or β-D-xylosidase. Growth occurs between 20 and 55°C and in the presence of adenine (0.5%, w/v), crystal violet (0.001%, w/v), phenyl ethanol (0.3%, v/v), potassium tellurite (0.01%, w/v), sodium azide (0.01%, w/v), chloramphenicol (32 μg/ml), chlortetracycline (4 μg/ml), gentamicin sulfate (8 μg/ml), neomycin sulfate (2 μg/ml), novobiocin (2 μg/ml), oleandomycin phosphate (32 μg/ml), penicillin G (16 μg/ml), polymyxin B (32 μg/ml), rifampin (4 μg/ml), streptomycin sulfate (2 μg/ml), tobramycin sulfate (8 μg/ml), and vancomycin (4 μg/ml).

Type strain shows the highest sequence similarity to: *S. lusitanus*, AB184424, 99.5%; *S. indiaensis*, AB184553, 99.3%; *S. longispororuber*, AB184440, 99.1%; *S. bellus*, AB184849, 99.1%; *S. cellulosae*, DQ442495, 99.1%; *S. coerulescens*, AY999720, 99.1%; *S. gancidicus*, AB184660, 99%; *S. lomondensis*, AB184673, 99%.

Source: not known.

DNA G+C content (mol%): 70.9 ± 0.4.

Type strain: AT37, CIP 105545, DSM 44293, NBRC 16323, JCM 10368.

Sequence accession no. (16S rRNA gene): U94490.

474. **Streptomyces thermocoprophilus** Kim, Al-Tai, Kim, Somasundaram and Goodfellow 2000, 506[VP]

ther.mo.co.pro.phi′lus. Gr. n. *therme* heat; Gr. n. *kopros* dung; Gr. adj. *philos* loving; N.L. masc. adj. *thermocoprophilus* dung-loving thermophile.

Moderately thermophilic actinomycete which forms a highly branched substrate mycelium and aerial hyphae which differentiate into long chains of straight spores which are cylindrical and have smooth surfaces (1.1–1.7 × 0.5 μm). Aerial spore mass color is gray. Diffusible pigments are formed on some standard media such as inorganic salts starch agar. Melanin pigments are produced on peptone-iron and tyrosine agars. Casein, starch, xanthine, and xylan are degraded but not adenine. L-Arabinose, D-fructose, D-galactose, D-glucose, *myo*-inositol, maltose, D-mannitol, D-mannose, and D-xylose are used as sole carbon sources for energy and growth but not carboxymethylcellulose, D-raffinose, starch, or sucrose. Growth occurs between 20 and 50°C and in the presence of ampicillin (10 μg/ml), erythromycin (15 μg/ml) and sodium chloride (7%, w/v) but not at 10 or 55°C. Growth is inhibited by chloramphenicol (30 μg/ml), gentamicin sulfate (15 μg/ml), kanamycin sulfate (30 μg/ml), neomycin sulfate (30 μg/ml), streptomycin sulfate (10 μg/ml), and tetracycline hydrochloride (30 μg/ml). Antimicrobial activity is shown against *Bacillus subtilis* NCIB 3610 but not towards *Escherichia coli* NCIB 9132 or *Staphylococcus aureus* ATCC 12600, or against representative strains of *Candida albicans*, *Curvularia lunata*, *Pestalotiopsis gnepini*, *Pyricularia oryzae*, and *Trichoderma viride*.

Type strain shows no sequence similarity over 99%.

Source: isolated from a sample of poultry feces collected from the poultry farm at the University of Malaya.

DNA G+C content (mol%): 68.6.

Type strain: B19, DSM 41700, JCM 10918, NBRC 100771.

Sequence accession no. (16S rRNA gene): AJ007402.

475. **Streptomyces thermodiastaticus** (Bergey, Harrison, Breed, Hammer and Huntoon 1923) Waksman 1953, 102[AL] (*Actinomyces thermodiastaticus* Bergey, Harrison, Breed, Hammer and Huntoon 1923)

ther.mo.di.a.sta′ti.cus. Gr. adj. *thermos* hot; N.L. adj. *diastaticus* starch-hydrolyzing; N.L. masc. adj. *thermodiastaticus* starch-hydrolyzing, heat-loving.

Spore chains in Section *Spirales*. Spirals are often irregular or imperfect; hooks or incomplete spirals and crooked spore chains are common. Mature spore chains are moderately short with 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Special incubation temperature: incubation temperatures used by ISP collaborators included 37, 45, 48, and 51°C; typical morphology, color reactions, and physiology are seen within this range. Spore surface is warty or spiny (very small "warts" or very blunt spines).

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar and glycerol-asparagine agar. Nearest matching color tabs in the Gray color series include 3fe, light brownish gray; 3ig, grayish yellowish brown; 3ge, light grayish yellowish brown; and 2ge, light olive brown. Colors are essentially the same at incubation temperatures from 37–51°C. Reverse side of colony is dark brown on yeast-malt agar; grayish yellow, yellowish brown, or olive brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When reddish (brown) pigment is present in the substrate mycelium, it is somewhat pH-sensitive, changing from reddish brown to olive brown or olive with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth except that a grayish yellow or olive yellow pigment is found in tyrosine agar in 2–4 d. Faint reddish (brown) or yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. When present, this pigment is pH-sensitive, changing from brownish to red with the addition of 0.05 M NaOH and from brownish to olive green with the addition of 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only traces of growth with sucrose. No difference in carbon utilization is seen on cultures incubated at 37 and 51°C.

Type strain shows the highest sequence similarity to: *S. thermospinosisporus*, AF333113, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27472, CBS 769.72, BCRC 12492, BCRC 12636, DSM 40573, HUT 6606, JCM 4840, NBRC 100020, NRRL B-5316, NRRL-ISP 5573, RIA 1429.

Sequence accession no. (16S rRNA gene): AB018095.

476. **Streptomyces thermogriseus** Xu, Tiang, Zhang, Zhao and Jiang 1998, 1093[VP]

ther.mo.gri′se.us. Gr. adj. *thermos* hot; N.L. adj. *griseus* gray; N.L. masc. adj. *thermogriseus* hot, gray.

Spores are spherical, subspherical, or short rods. Spore surface is smooth. Brown or yellow vegetative hyphae are produced, becoming black after autolysis. Neither diffusible pigment nor melanin is produced. Milk is coagulated and peptonized. Hydrolyzes starch. Reduces nitrate. No H_2S production. No growth on cellulose. No degradation of urea. Utilizes rhamnose and mannitol. May or may not utilize glucose, fructose, xylose, raffinose, ribitol, and cellobiose. Does not utilize inositol. Lecithinase may or may not be produced. No resistance to neomycin or rifampin. No antimicrobial activities are detected. Grows at 65–68°C and in 0.1% phenol. Growth or no growth in 7% NaCl. The cell wall contains LL-A_2pm and glycine. The whole-cell hydrolysate contains galactose.

Type strain shows the highest sequence similarity to: *S. thermovulgaris*, Z68094, 100%.

Source: Strain Y-4027 (=CCTCC AA 97012) was isolated from soil samples of Kunming, Y-5114 (=CCTCC AA97013) was from Chenghai Lake and Y-14046^T (=CCTCC AA 97014^T) and Y-14082 (=CCTCC AA97015) were from a hot-spring in Eryuan, Yunnan, China.

DNA G+C content (mol%): not known.

Type strain: Y-14046, CCTCC AA 97014, CIP 105834, DSM 41756, JCM 11269, NBRC 100772.

Sequence accession no. (16S rRNA gene): AB249980.

477. **Streptomyces thermolineatus** Goodfellow, Lacey and Todd 1988, 329[VP] (Effective publication: Goodfellow, Lacey and Todd 1987a, 3147.)

ther.mo.lin.e.a′tus. Gr. fem. n. *therme* heat, L. part. adj. *lineatus* reduced to a straight line, to made straight; N.L. masc. adj. *thermolineatus* heat-loving linear (referring to the spore chains).

Spores in straight or flexuous chains less than 30 spores long. Spores are smooth but ends often prolonged, projecting from the oval spore body and retaining their shape under vacuum when the rest of the spore collapses, to give a phalangiform appearance (Tresner et al., 1966). Spores measure 1.0–2.1 × 0.9–1.3 μm (mean 1.43 × 1.06 μm). Good growth at 40°C on V-8 juice agar, producing abundant aerial mycelium in the green color series, 24ih to 24½ih. Reverse of colony is yellow-brown with no distinctive pigments. No melanoid pigment produced on peptone-iron agar. Degrades casein, gelatin, and starch. Uses trehalose and sometimes cellobiose and mannitol as sole carbon sources, and L-arginine, L-histidine, L-hydroxyproline, L-methionine, L-phenylalanine, potassium nitrate, L-serine, and L-valine as sole nitrogen sources. Reduces nitrate to nitrite and sometimes shows lipolytic and proteolytic activity on egg yolk.

Type strain shows no sequence similarity over 99%.

Source: isolated from sewage compost.

DNA G+C content (mol%): not known.

Type strain: K47, A1484, ATCC 51534, DSM 41451, HUT 6609, NBRC 14750, JCM 6307, NCIMB 12471.

Sequence accession no. (16S rRNA gene): Z68097.

478. **Streptomyces thermonitrificans** Desai and Dhala 1967, 137[AL]

ther.mo.ni.tri′fi.cans. Gr. n. *therme* heat; N.L. part. adj. *nitrificans* nitrifying; N.L. part. adj. *thermonitrificans* heat, nitrifying, referring to thermophily and vigorous nitrate reduction of the organism.

Spore chains in Section *Rectiflexibiles* or *Spirales*. Short spore chains often have only 3–10 spores per chain. On yeast-malt agar, salts-starch agar, and glycerol-asparagine agar, the chains are usually crooked or twisted. Longer chains may form irregular and imperfect spirals, especially on oatmeal agar and occasionally on salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series when adequate sporulation occurs on yeast-malt agar, oatmeal agar, and salts-starch agar. Immature aerial mycelium is white; sporulating aerial mycelium is not found on glycerol-asparagine agar. Nearest matching color tabs are 3li and 4li, brownish gray; 3ge, light grayish yellowish brown; and 2ge, light olive brown. Reverse side of colony with no distinctive pigments (grayish olive to dark grayish brown on yeast-malt agar; grayish yellow to grayish yellow-

ish green or grayish olive on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth according to ISP observers [the original description by Desai and Dhala (1967) states that this strain is H_2S- and melanin-positive]. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-xylose, iso-inositol, D-mannitol, D-fructose, and sucrose are utilized for growth. No growth or only traces of growth with L-arabinose, rhamnose, and raffinose.

For sequence similarity, see type strain of *Streptomyces thermovulgaris*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 23385, CBS 774.72, DSM 40579, NBRC 13473, NBRC 16616, IMET 43405, JCM 4841, LMG 19341, NCIM 2007, NRRL-ISP 5579, RIA 1434.

Sequence accession no. (16S rRNA gene): Z68098.

Further comments: according to Kim et al. (1999), *Streptomyces thermonitrificans* Desai and Dhala 1967 is a later heterotypic synonym of *Streptomyces thermovulgaris* Henssen 1957.

479. **Streptomyces thermospinosisporus** corrig. Kim and Goodfellow 2002, 1227[VP]

ther.mo.spi.ni.spo′rus. Gr. adj. *thermos* hot; L. adj. *spinosus* spiny; N.L. n *spora* a spore; N.L. masc. adj. *thermospinisporus* heat-loving, spiny spores.

Moderately thermophilic, facultatively carboxydotrophic actinomycete which forms extensively branched aerial and substrate hyphae. Aerial hyphae differentiate into flexuous chains of spores that show spiny ornamentation. Aerial spore mass is gray, but the substrate mycelium has no distinctive pigments. Soluble pigments are not produced, nor are melanin pigments formed on peptone-yeast extract-iron agar. Utilizes carbon monoxide and carbon dioxide as sole sources of carbon for energy and growth. Nitrate is reduced, and elastin, starch, and L-tyrosine are degraded. Growth is inhibited in the presence of phenol (0.1%, w/v), phenyl ethanol (0.3%, w/v), and sodium azide (0.02%, w/v). *myo*-Inositol, mannitol, raffinose, sucrose and sodium pyruvate are used as sole carbon sources when the organism is grown heterotrophically. Contains major amounts of LL-A_2pm, octahydrogenated menaquinones with nine isoprene units as the predominant isoprenolog, and major amounts of diphosphatidylglycerol and phosphatidylethanolamine.

Type strain shows the highest sequence similarity to: *S. thermocarboxydovorans*, U94489, 99.1%; *S. thermodiastaticus*, AB018095, 99%. Type strain shows DNA–DNA similarity to: *S. thermocarboxydovorans* DSM 44296^T, 72%; *S. thermodiastaticus* DSM 40573^T, 72%.

Source: not known.

DNA G+C content (mol%): 73.6.

Type strain: AT10, DSM 41779, JCM 11756, KCTC 9909, NBRC 100043.

Sequence accession no. (16S rRNA gene): AF333113.

Further comments: the original spelling *Streptomyces thermospinisporus* (*sic*) has been corrected by the List Editor, IJSEM.

480a. **Streptomyces thermoviolaceus subsp. thermoviolaceus** Henssen 1957, 388[AL]

ther.mo.vi.o.la′ce.us. Gr. n. *therme* heat; L. adj. *violaceus* violet colored; N.L. masc. adj. *thermoviolaceus* heat, violet colored (probably referring to the thermophilic nature of the species and the violet color of the aerial mycelium).

Spore chains in Section *Spirales*. Spirals are best developed on carbon-utilization medium plus raffinose. Imperfect spirals or loops may be common on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5dc, grayish yellowish pink) when adequate sporulating aerial mycelium is present, but sporulation is generally poor on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar at 28°C. ISP observers did not incubate at the higher temperatures (40–50°C) recommended by Henssen. Reverse side of colony with no distinctive pigments (olive brown on yeast-malt agar and oatmeal agar; grayish yellow to pale greenish yellow on salts-starch agar and glycerol-asparagine agar). The reverse mycelium pigment is pH-sensitive, changing from yellow or brown to gray or bluish gray with addition of 0.05 M NaOH and becomes reddish with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Red or violet pigment is found in the medium in yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. This pigment is pH-sensitive, changing from violet to blue with the addition of 0.05 M NaOH and from violet to red with the addition of 0.05 M HCl.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Utilization of L-arabinose is doubtful. No growth or only traces of growth with iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. thermoviolaceus* subsp. *apingens*, Z68095, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1471, ATCC 19283, CBS 278.66, CBS 688.72, BCRC 12493, BCRC 12639, DSM 40443, HAMBI 1006, HUT 6604, NBRC 13905, IMET 43353, JCM 4337, JCM 4843, LMG 14943, LMG 19359, NCIMB 10076, NRRL B-12374, NRRL-ISP 5443, RIA 1348, VKM Ac-1857.

Sequence accession no. (16S rRNA gene): Z68096.

480b. **Streptomyces thermoviolaceus subsp. apingens** Henssen 1957, 390[AL]

a.pin′gens. Gr. pref. *a*- denoting negation, not; L. part. adj. *pingens* coloring; N.L. part. adj. *apingens* not coloring.

Aerial hyphae straight or branched, spore chains coiled, 20–40 μm long, spores 10–20, oval, 1.0–1.2 × 1.2–1.6 μm. Substrate mycelium is hardly branched. Colonies are yellowish to ochre brown, aerial mycelium white to violet gray. Physiological characteristics under

aerobic and anaerobic conditions at 50°C are as follows. On cellulose-dextrin agar: weak growth, aerial mycelium formed, colonies light brownish. On meat-extract agar: weak growth, aerial mycelium hardly formed, colonies yellow. On casein-glucose agar: weak growth, gray aerial mycelium. On asparagine-glycerol agar: good growth, gray aerial mycelium, colonies yellow. On Czapek's agar: weak growth, gray aerial mycelium. On yeast agar: weak growth, aerial mycelium white to gray. On yeast-glucose agar: good growth, thick, violet-gray aerial mycelium, colonies ochre brown. On potato agar I: good growth, thick, gray aerial mycelium, colonies ochre brown. On potato agar II: good growth, no aerial mycelium, colonies colorless to yellowish. On potato wedge: good growth, aerial mycelium at most marginal, colonies yellowish. Starch is quickly hydrolyzed. Grows on nitrate but does not form nitrite from nitrate. Milk is quickly coagulated and peptonized. Gelatin and nutrient-gelatin are mostly liquefied, colonies are orange yellow. This subspecies grows well at 50°C under exclusion of oxygen. Growth is weak at 28 and 60°C, aerial mycelium is not found; colonies are mostly yellow or brownish.

Type strain shows the highest sequence similarity to: *S. thermoviolaceus* subsp. *thermoviolaceus*, Z68096, 99.4%; *S. mexicanus*, AB249966, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19994, CBS 140.67, DSM 41392, NBRC 15459, JCM 4312, NCIMB 10077.

Sequence accession no. (16S rRNA gene): Z68095.

481. **Streptomyces thermovulgaris** Henssen 1957, 391[AL]

ther.mo.vul.ga′ris. Gr. n. *therme* heat; L. adj. *vulgaris* common; N.L. masc. adj. *thermovulgaris* heat, common.

Spore chains in Section *Spirales* on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar when incubated at 40–50°C for 14 d. *Retinaculiaperti* or flexuous spore chains may also be found. At 28°C, some flexuous spore chains (only) may be found on these media, but aerial mycelium is usually absent or poorly developed at 28°C. Spore surface is smooth. Thermophilic with optimum growth at 40–50°C. Sclerotia-like masses of spore chains are common.

Color of colony: aerial mass color in the Gray color series (usually 3ig or 4ig, light grayish brown; 3fe, light brownish gray or 2dc, yellowish gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. At suboptimal temperatures, the aerial mycelium is white. Reverse side of colony with no distinctive pigments (light yellow or pale grayish yellow to olive-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth, but growth on rhamnose or raffinose may be less than on the other carbon sources tested.

Type strain shows the highest sequence similarity to: *S. thermogriseus*, AB249980, 100%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1455, ATCC 19284, ATCC 25501, CBS 276.66, CBS 643.69, BCRC 12488, BCRC 12638, DSM 40444, HUT 6605, NBRC 13089, NBRC 16615, JCM 4338, JCM 4520, NCIMB 10078, NRRL B-12375, NRRL-ISP 5444, RIA 1281, VKM Ac-1745.

Sequence accession no. (16S rRNA gene): Z68094.

Further comments: according to Kim et al. (1999), *Streptomyces thermovulgaris* Henssen 1957 is an earlier heterotypic synonym of *Streptomyces thermonitrificans* Desai and Dhala 1967.

482. **Streptomyces thioluteus** (Okami 1952) Witt and Stackebrandt 1991, 456[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) (*Streptomyces thioluteus* Okami 1952, 30; *Verticillomyces thioluteus* Shinobu 1965, 161; *Streptoverticillium thioluteum* Baldacci, Farina and Locci 1966, 165)

thi.o.lu′te.us. Gr. n. *theion* (L. translit. *thium*) sulfur; L. adj. *luteus* yellow; N.L. masc. adj. *thioluteus* sulfur-yellow in color.

Good growth on potato-glucose agar (Baldacci et al., 1954). Color: reverse, orangish yellow; aerial mycelium, yellowish. On Bacto Czapek agar: very poor growth. Color: colorless; whitish tufts of aerial mycelium. On Casamino acids Czapek agar (1 g/l Difco vitamin-free Casamino acids, replacing sodium nitrate): limited growth. Color: reverse, colorless to yellowish; aerial mycelium, whitish yellow. On glucose asparagine agar (ISP medium 5 with 1% glucose replacing glycerol): good growth. Color: reverse, yellow to brown yellow; poor aerial mycelium, yellowish. On glucose-asparagine agar: good growth. Color: reverse, yellowish brown; aerial mycelium, yellowish. On inorganic salts-starch agar: good growth. Color: reverse, yellowish; aerial mycelium, yellowish. On yeast extract-malt extract agar: good growth. Color: reverse, brown; aerial mycelium, yellowish; soluble pigments present. On Bacto Emerson agar: good growth. Color: reverse, brown; aerial mycelium, greenish yellow; traces of soluble pigment. On Bennett agar (1% glucose, 0.1% Bacto beef agar, 0.1% yeast extract, 0.2% peptone, 1.5% agar): good growth. Color: reverse, yellow to brown-yellow; aerial mycelium, yellowish. On Oxoid nutrient agar: medium growth. Color: aerial mycelium, greenish yellow; reverse, brownish yellow; traces of aerial mycelium and pigment. Grows at 37°C; however, no aerial mycelium is produced in 15 d. No growth at 45°C. Some cultures form traces of H_2S and utilize rhamnose and casein. The type strain produces propiopyrrothine (aureothricin) and aureothin.

Type strain shows the highest sequence similarity to: *S. morookaense* AJ781349, 99.5%; *S. abikoensis*, AB184537, 99.3%; *S. lavenduligriseus*, DQ442515, 99.2%; *S. olivoverticillatus*, AB184636, 99.1%; *S. sapporonensis*, AB184508, 99%; *S. luteireticuli* AB249969, 99%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 12310, CBS 642.72, BCRC 12428, DSM 40027, DSM 41486, HUT 6071, NBRC 13341, NBRC 3364, JCM 4087, JCM 4844, NRRL B-1667, NRRL-ISP 5027, RIA 1302, VKM Ac-1914.

Sequence accession no. (16S rRNA gene): AB184753.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces thioluteus* is proposed as a *nomen revictum* (basonym: "*Streptomyces thioluteus*" Okami 1952).

483. **Streptomyces torulosus** Lyons and Pridham 1971, 192[AL]

to.ru.lo′sus. L. dim. n. *torulus* a small protuberance; L. masc. suff. *-osus* suffix used with the sense of full of, prone to; N.L. masc. adj. *torulosus* having small protuberances.

Spores are arranged in both dextrorse and sinistrorse coiled chains, with three to five volutions per coil. The color of the aerial mycelium observed with inorganic salts-starch agar after 14 d at 28°C was placed in the Gray series. A brown to black diffusible pigment is formed in peptone-iron agar. Melanin-like chromogenicity: Brown to black diffusible pigments are formed in tryptone-glucose-liver extract-yeast extract (Lyons and Pridham, 1965) broth. D-Glucose, D-xylose, L-arabinose, L-rhamnose, D-fructose, D-galactose, raffinose, D-mannitol, and iso-inositol are utilized; salicin is not. Growth is excellent on Czapek's solution-sucrose agar. The L-form of A_2pm is found in whole-cell hydrolysates. Faint spots for mannose and arabinose also can be detected. Strains are sensitive to streptomycin. The type strain is able to inhibit *Bacillus subtilis*, *Sarcina lutea*, *Escherichia coli*, and *Mucor ramannianus*. *Saccharomyces pastorianus* was very slightly inhibited, and *Candida albicans* was not inhibited.

Type strain shows the highest sequence similarity to: *S. hygroscopicus* subsp. *ossamyceticus*, AB184560, 100%; *S. neyagawaensis*, D63869, 99.3%; *S. ipomoeae*, AB184857, 99.2%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 29340, CBS 801.71, DSM 40894, IFM 1283, NBRC 15460, JCM 4872, NRRL B-3889.

Sequence accession no. (16S rRNA gene): AJ781367.

484. **Streptomyces toxytricini** (Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 68[AL] ("*Actinomyces toxytricini*" Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 47)

to.xy.tri.ci′ni. N.L. n. *toxythricinum* toxythricin a suggested, but never used, antibiotic name; N.L. gen. n. *toxytricini* of toxithricin.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Long spore chains of the *Retinaculiaperti* type as well as straight to flexuous sporophores are common on salts-starch agar, glycerol-asparagine agar, yeast-malt agar, and oatmeal agar. Spirals are most numerous as long chains of more than 50 spores on yeast-malt agar and oatmeal agar. Chains of 10 to 50 or more spores per chains are also found on salts-starch agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series on yeast-malt agar, oatmeal agar, and salts-starch agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar or glycerol-asparagine agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments formed in peptone-yeast-iron agar and tryptone-yeast extract broth. Pigments other than melanoids not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose is utilized for growth. Doubtful traces of growth or no growth on L-arabinose, sucrose, D-xylose, iso-inositol, rhamnose, and raffinose. Utilization of D-mannitol and D-fructose is also doubtful.

Type strain shows the highest sequence similarity to: *S. globosus*, AJ781330, 100%; *S. flavotricini*, AB184132, 99.3%; *S. racemochromogenes*, DQ026656, 99.1%; *S. polychromogenes*, AB184292, 99%.

485. **Streptomyces tricolor** (Wollenweber 1920) Waksman 1961, 158[AL] emend. Lanoot, Vancanneyt, Dawyndt Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt Cnockaert, Zhang, Huang, Liu and Swings 2004, 90.) ("*Actinomyces tricolor*" Wollenweber 1920, 13)

tri′co.lor. L. masc. adj. *tricolor* of three colors.

Forms yellow-, red-, or blue-colored vegetative mycelium on some media; forms blue diffusible pigment on some media.

Type strain shows the highest sequence similarity to: *S. anthocyanicus*, AB184631, 100%; *S. rubrogriseus*, AB184681, 99.9%; *S. violaceoruber*, AF503492, 99.9%; *S. coelescens*, AF503496, 99.9%; *S. violaceolatus* AF503497, 99.8%; *S. humiferus*, AF503491, 99.8%; *S. lienomycini*, AJ781353, 99.7%; *S. violaceorubidus*, AJ781374, 99.5%; *S. tendae*, D63873, 99.4%; *S. coelicoflavus*, AB184650, 99.4%; *S. pactum*, AB184398, 99.1%; *S. olivaceus*, AB184743, 99%.

Source: isolated from flat scab of potato.

DNA G+C content (mol%): not known.

Type strain: CBS 103.21, DSM 41704, NBRC 15461, JCM 5065, NRRL B-16925.

Sequence accession no. (16S rRNA gene): AB184687.

Further comments: according to Lanoot et al. (2004), *Streptomyces tricolor* (Wollenweber 1920) Waksman 1961[AL] is an earlier heterotypic synonym of *Streptomyces roseodiastaticus* (Duché 1934) Waksman 1953.

486. **Streptomyces tubercidicus** Nakamura 1961, 90[AL]

tu.ber.ci′di.cus. L. n. *tuber* nodule; L. v. *caedo* to kill; N.L. masc. adj. *tubercidicus* nodule destroying, referring to antitumor activity of the antibiotic.

Spore chains in Section *Spirales*. Mature spore chains generally have 3 to 10 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (d, light gray to 3fe, light brownish gray) on yeast-malt agar, oatmeal agar, and salts-starch agar in 14 d. One observer places 21 d culture in the Red color series (5dc, grayish yellowish pink) on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. The original description notes a tendency for the aerial mycelium to become moist and black; this hygroscopic characteristic is not recorded by ISP observers. Reverse side of colony is grayish yellow to yellowish brown or olive-brown on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; moderate brown to dark brown on yeast-malt agar. Reverse mycelium pigment is a pH indicator, changing from yellow or yellow-brown to pale pink with addition of 0.05 M NaOH and from pink or grayish brown to yellow with addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow to pink or violet-pink (depending upon pH) pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive showing the same changes noted for the reverse mycelium pigment.

D-Glucose, iso-inositol, D-mannitol, D-fructose, sucrose, and raffinose are utilized for growth. No growth or only trace of growth with L-arabinose, D-xylose, and rhamnose.

Type strain shows the highest sequence similarity to: *S. libani* subsp. *libani*, AB184414, 100%; *S. nigrescens*, DQ442530, 99.9%; *S. hygroscopius* subsp. *glebosus*, AB184479, 99.6%; *S. libani* subsp. *rufus*, AJ781351, 99.6%; *S. caniferus*, AB184640, 99.5%; *S. catenulae*, AJ621613, 99.5%; *S. misakiensis*, AB217605, 99.5%; *S. sioyaensis*, DQ026654, 99.5%; *S. platensis*, AB045882, 99.5%; *S. hygroscopius* subsp. *decoyicus*, AY999883, 99.2%; *S. lydicus*, Y15507, 99.1%; *S. chattanoogensis*, AJ621611, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1414, ATCC 25502, CBS 644.69, BCRC 11886, CECT 3272, DSM 40261, IFM 1064, NBRC 13090, IMET 43517, JCM 4054, JCM 4558, KCTC 9109, LMG 19361, NRRL B-5440, NRRL-ISP 5261, RIA 1282, VKM Ac-1073.

Sequence accession no. (16S rRNA gene): AJ621612.

487. **Streptomyces tuirus** Albert and Malaquias de Queiroz 1963, 43[AL]

tu'ir.us. Nheêngatû Amazonian dialect *tuira* violet, violet-blue; N.L. masc. adj. *tuirus* violet, violet-blue (referring to the color of vegetative mycelium and diffusible pigment).

Spore chains in Section *Spirales*. Spiral spore chains often arise in verticils from long axial hyphae, suggesting monoverticillate morphology. Spirals are usually open and wavy; hooked spore chains are also present. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (5fe, light grayish reddish brown; 2dc, yellowish gray; d-e, light to medium gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with distinctive red pigments on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Reverse color is reddish black on yeast-malt agar and grayish reddish brown, dark pale red, or dark grayish pink on salts-starch agar and glycerol-asparagine agar; grayish brown on oatmeal agar. One of three observers reports that the reverse mycelium pigment is a pH indicator, changing from red to violet with the addition of 0.05 M NaOH and to a more intensive red with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth. Melanin reaction may be weak or absent in tyrosine agar. Red, reddish brown, or violet pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. According to one observer, only, this pigment is pH-sensitive, showing the same changes observed in the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. mutabilis*, EF178679, 99.6%; *S. rochei*, AB184237, 99.5%; *S. vinaceusdrappus*, AY999929, 99.5%; *S. plicatus*, AB184291, 99.5%; *S. minutiscleroticus*, EF178696, 99.5%; *S. ghanaensis*, AY999851, 99.5%; *S. geysiriensis*, DQ442501, 99.5%; *S. levis*, AB184670, 99.4%; *S. djakartensis*, AB184657, 99.4%; *S. luteogriseus*, AB184379, 99.4%; *S. capillispiralis*, AB184577, 99.2%; *S. janthinus*, AB184851, 99.2%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 99.2%; *S. roseoviolaceus*, AJ399484, 99.2%; *S. azureus*, EF178674, 99.2%; *S. violaceus*, AB184315, 99.2%; *S. africanus*, AY208912, 99.1%; *S. gancidicus*, AB184660, 99.1%; *S. pseudogriseolus*, DQ442541, 99.1%; *S. afghaniensis*, AJ399483, 99.1%; *S. calvus*, AB184329, 99.1%; *S. virens*, DQ442554, 99%; *S. cellulosae*, DQ442495, 99%; *S. violaceorubidus*, AJ781374, 99%; *S. anandii*, AB184402, 99%; *S. flavoviridis*, AB184842, 99%; *S. lomondensis*, AB184673, 99%; *S. pilosus*, AB184161, 99%; *S. aureorectus*, AB184710, 99%; *S. asterosporus*, AB184706, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 19007, CBS 719.72, BCRC 12217, DSM 40505, NBRC 15617, JCM 4255, JCM 4846, NRRL B-3631, NRRL-ISP 5505, RIA 1379.

Sequence accession no. (16S rRNA gene): AB184690.

488. **Streptomyces turgidiscabies** Miyajima, Tanaka, Takeuchi and Kuninaga 1998, 500[AL]

tur.gi.di.sca'bi.es. L. adj. *turgidus* swollen; L. fem. n. *scabies* scabbiness; N.L. fem. n. *turgidiscabies* a swollen scabbiness.

Spores are 0.5–0.6 × 1.0–1.2 µm, smooth, gray, and are borne in mature flexuous chains containing 8 or more spores. Diffusible pigments and melanin are not produced. Positive for peptonization but not for coagulation of milk, is not susceptible to 25 µg/ml oleandomycin or 10 IU/ml penicillin G and is not positive for utilization

of sodium acetate or sodium propionate as sole carbon sources. L-Arabinose, D-fructose, D-glucose, D-mannitol, iso-inositol, rhamnose, sucrose, D-xylose, and raffinose are used as carbon sources. None of the strains studied degrade xanthine or grow at 37°C and all are susceptible to 20 µg/ml streptomycin, 0.5 µg/ml crystal violet, 100 µg/ml potassium tellurite, and 0.1% phenol. Cell wall contains the LL-A_2pm isomer. *S. turgidiscabies* differs from other potato scab pathogens in having gray, smooth, flexuous spore chains.

Type strain shows the highest sequence similarity to: *S. reticuliscabiei*, AJ007428, 99.1%.

Source: the type strain was isolated from raised scab lesions on potato tubers in eastern Hokkaido, Japan, in 1991, and has been confirmed to be pathogenic.

DNA G+C content (mol%): 70.9–72.5.

Type strain: SY9113, ATCC 700248, CIP 105577, NBRC 16080, JCM 10429, NRRL B-24078.

Sequence accession no. (16S rRNA gene): AB026221.

Further comments: a numerical analysis of phenotypic characteristics showed that *Streptomyces reticuliscabiei* Bouchek-Mechiche et al. 2000 and *Streptomyces turgidiscabies* Miyajima et al. 1998 belong to the same cluster and share almost all morphological and biochemical traits that are important in the identification of *Streptomyces* species. DNA–DNA hybridization and phylogenetic comparisons of 16S rRNA gene sequences confirm that the two species are genomically closely related. In contrast, pathological data showed that *Streptomyces turgidiscabies* and *Streptomyces reticuliscabiei* cause two distinct diseases. For the pathologist, the fusion of *Streptomyces reticuliscabiei* and *Streptomyces turgidiscabies* under a single species denomination would cause confusion of separate diseases and create a discrepancy between taxonomists and pathologists. Therefore, Bouchek-Mechiche et al. think that the two groups should continue to carry their current denominations, i.e. *Streptomyces reticuliscabiei* Bouchek-Mechiche et al. 2000 for the strains inducing netted scab and *Streptomyces turgidiscabies* Miyajima et al. 1998 for those causing common scab.

489. **Streptomyces umbrinus** (Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 61[AL] ("*Actinomyces umbrinus*" Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 62)

um.bri′nus. N.L. masc. adj. *umbrinus* wood brown, the color of the aerial mycelium.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (3ca, pale orange-yellow to 5cb, grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is reddish brown on yeast-malt agar, light brown to strong brown on oatmeal agar and salts-starch agar, gray to reddish black on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. ederensis*, AB184658, 100%; *S. phaeochromogenes*, AB184738, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19929, ATCC 25503, CBS 645.69, DSM 40278, NBRC 13091, INA 1703/53, JCM 4521, NRRL B-2572, NRRL-ISP 5278, RIA 1283, VKM Ac-1747.

Sequence accession no. (16S rRNA gene): AB184305.

490. **Streptomyces variabilis** (Preobrazhenskaya, Ryabova and Blinov *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict. 1958, 70[AL] ("*Actinomyces variabilis*" Preobrazhenskaya, Ryabova and Blinov *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957)

va.ri.a′bi.lis. L. masc. adj. *variabilis* variable.

Spore chains in Section *Spirales*. Open spirals are conspicuous on salts-starch agar, rare on yeast-malt agar. Flexuous spore chains, loops, hooks, and spirals suggestive of Section *Retinaculiaperti* are observed on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny. Spines are short; one observer reports warty to smooth spores.

Color of colony: aerial mass color in the Gray color series on oatmeal agar and salts-starch agar; Gray or Red series on yeast-malt agar. Aerial spore mass is not well-developed on glycerol-asparagine agar. Reverse side of colony with no distinctive pigment on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; reddish brown on yeast-malt agar.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar or tyrosine agar. No pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. erythrogriseus*, AJ781328, 100%; *S. labedae*, AB184704, 100%; *S. griseoincarnatus*, AJ781328, 100%; *S. griseorubens*, AB184139, 99.9%; *S. griseoflavus*, AJ781322, 99.6%; *S. matensis*, AB184221, 99.6%; *S. althioticus*, AY999808, 99.2%; *S. paradoxus*, AB184628, 99.2%; *S. heliomycini*, AB184712, 99.1%; *S. collinus*, AB184123, 99.1%; *S. flaveolus*, AB184764, 99.1%; *S. viridochromogenes*, DQ442555, 99%; *S. bellus*, AB184849, 99%; *S. viridodiastaticus*, AY999852, 99%; *S. violaceochromogenes*, AY999867, 99%; *S. malachitofuscus*, AB184282, 99%; *S. violaceorubidus*, AJ781374, 99%; *S. coerulescens*, AY999720, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19815, ATCC 19930, CBS 568.68, BCRC 11488, DSM 40179, NBRC 12825, IMET 42059, JCM 4422, NRRL B-3984, NRRL-ISP 5179, RIA 1095, UNIQEM 202, VKM Ac-1854.

Sequence accession no. (16S rRNA gene): DQ442551.

491. **Streptomyces variegatus** Sveshnikova and Timuk 1986, 575[VP] (Effective publication: Sveshnikova and Timuk *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

va.ri.e.ga′tus. L. masc. part. adj. *variegatus* variegated, made of various colors.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: aerial mycelium is pink to loud pink; substrate mycelium is raspberry red and green, grayish brownish green. Intensity of building pigments is different, normally first red colored, later covered by green color; no diffusible pigment. Curious color of substrate mycelium is due to pigment types prodigiosin and ferroverdin. On starch-ammonia agar: aerial mycelium grows late, light pink, poor; substrate mycelium is light pink with weak violet shadow; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is white, poorly developed, sometimes absent; substrate mycelium is green with raspberry colored segments, sometimes brindled green, greenish grayish brown, light yellow, and grayish brownish pink at the same time; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is whitish to light pink and pink; substrate mycelium is brindled light yellow, orange, raspberry colored, grayish brownish red, and dark green; no diffusible pigment. On glucose-asparagine agar: aerial mycelium whitish to light pink and pink; substrate mycelium is brindled yellow, green, and light raspberry colored; no diffusible pigment. On agar Sp I Krasil'nikov: weak growth; no aerial mycelium; colorless substrate mycelium; no diffusible pigment. On oatmeal agar: aerial mycelium is whitish to light pink; substrate mycelium is yellow, pale orange, pink to raspberry colored; green pigment is weak; no diffusible pigment. On organic agar 2: aerial mycelium is whitish to pink; substrate mycelium is brindled, pale red, pale greenish; no diffusible pigment. Melanoid pigments are not formed. Grows on fructose, xylose, and arabinose; no growth on sucrose, rhamnose, or raffinose. Antibiotic: antibiotic of group α-oxi-keto-Pentaen; pigment with antibiotic character of the prodigiosin group.

Type strain shows the highest sequence similarity to: *S. fulvissimus*, AB184434, 99.1%; *S. alboflavus*, EF178699, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 43696, DSM 41464, NBRC 15462, INA T-511, JCM 6930, VKM Ac-846.

Sequence accession no. (16S rRNA gene): AJ781371.

492. **Streptomyces varsoviensis** Kurylowicz and Woźnicka 1967, 1[AL]

var.so.vi.en′sis. N.L. masc. adj. *varsoviensis* of or pertaining to Varsovia; named for Warsaw, Poland.

Spore chains in Section *Spirales*, *Retinaculiaperti*, or *Rectiflexibiles*. Spiral spore chains are abundant on yeast-malt agar; straight to flexuous chains are most common on glycerol-asparagine agar. Flexuous, spiral, or intermediate (*Retinaculiaperti*) forms may be found on oatmeal agar and salts-starch agar but sporulating aerial mycelium is usually poorly developed on these media. Spore surface is smooth.

Color of colony: aerial mass color in the White or Yellow (2ba, pale yellow) color series on oatmeal agar and salts-starch agar. Sporulation on oatmeal agar and salts-starch agar is usually inadequate for spore mass color determination. Reverse side of colony is yellow to yellow-brown and modified by red (to yellowish pink, orange, grayish reddish orange, or strong brown) on yeast-malt agar, salts-starch agar, and glycerol-asparagine agar. Substrate pigment is not a pH indicator or is modified only slightly by addition of 0.05 M NaOH or HCl.

Color in medium: reports vary on production of melanoid pigments. Some darkening of peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth may be seen in 4 d, but usually not in 2 d. Gause's organic medium no. 2 is not darkened in 2–4 d. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose and D-mannitol are utilized for growth. Utilization of fructose is doubtful. No growth or only trace of growth with L-arabinose, D-xylose, iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. sapporonensis*, AB184508, 99.5%; *S. abikoensis*, AB184537, 99.2%; *S. hygroscopius* subsp. *angustmyceticus*, DQ442509, 99.1%; *S. luteireticuli* AB249969, 99.1%; *S. ehimensis*, AY999834, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1431, ATCC 14631c, ATCC 25505, CBS 357.64, CBS 647.69, BCRC 12647, DSM 40346, HAMBI 1046, NBRC 13093, IMET 43351, JCM 4303, JCM 4523, NCIMB 9522, NRRL B-3589, NRRL-ISP 5346, RIA 1285, VKM Ac-1000.

Sequence accession no. (16S rRNA gene): DQ026653.

493. **Streptomyces vastus** Szabó and Marton 1958, 245[AL]

vas′tus. L. masc. adj. *vastus* empty, unoccupied, waste, referring to the occurrence of the organism in the Hortobagy Puszta (eastern Hungary).

Spore chains in Section *Spirales*. Open, terminal spirals of only one to three turns may be seen on yeast-malt agar, oatmeal agar, and salts-starch agar, but sporulating aerial mycelium is usually poorly developed on these media. Sporulation may be absent on glycerol-asparagine agar and Gause's medium no. 1. Poor sporulation of this strain on various media is noted in Szabó and Marton's original description (op. cit.). Spore chains are often short with 3 to 10 or more spores per chain. Spore surface is smooth.

Color of colony: aerial mass color in the White or Gray color series on yeast-malt agar and oatmeal agar when mature sporulating aerial mycelium is formed. Thin,

white aerial mycelium may also be seen on salts-starch agar and glycerol-asparagine agar but is inadequate for accurate color determination. Reverse side of colony is grayish green on yeast-malt agar; colorless to pale blue or grayish blue on oatmeal agar and salts-starch agar; colorless to pale yellow on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in oatmeal agar or glycerol-asparagine agar. Traces of yellow or green pigment may or may not be found in yeast-malt agar and a trace of blue pigment may be found in salts-starch agar. This pigment, if present, is not a pH indicator when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth. Reports vary on utilization of D-xylose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25506, CBS 290.60, CBS 648.69, DSM 40309, NBRC 13094, JCM 4524, NRRL B-12232, NRRL-ISP 5309, RIA 1286, VKM Ac-1871.

Sequence accession no. (16S rRNA gene): DQ442552.

494. **Streptomyces venezuelae** Ehrlich, Gottlieb, Burkholder, Anderson and Pridham 1948, 467[AL]

ve.ne.zu.e′la.e. N.L. gen. n. *venezuelae* of Venezuela.

Spore chains in Section *Rectiflexibiles.* Straight spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; sporulation may be poor on yeast-malt agar. One observer, only, records fragmentation of substrate mycelium on glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray to 5fe, light grayish reddish brown) on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; a good spore is usually not produced on yeast-malt agar. Reverse side of colony with no distinct pigments (grayish yellow) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but only weakly or not at all in tyrosine agar. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, and rhamnose are utilized for growth. A trace of growth is usually found in iso-inositol, D-mannitol, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. zaomyceticus*, EF178685, 99.9%; *S. exfoliatus*, AB184324, 99.9%; *S. lateritius*, AB184324, 99.9%; *S. wedmorensis*, DQ442557, 99.7%; *S. litmocidini*, AB184149, 99.6%; *S. omiyaensis*, EF178697, 99.6%; *S. yereyanensis* EF178684, 99.4%; *S. narbonensis*, DQ445794, 99.3%.

Source: not known.

Sequence accession no. (16S rRNA gene): AB045890.

495. **Streptomyces vietnamensis** Zhu, Guo, Yao, Yang, Deng, Phuong, Hanh and Ryan 2007, 1773[VP]

vi.et.nam.en′sis. N.L. masc. adj. *vietnamensis* of or pertaining to Vietnam, the geographical location from where the type strain was isolated.

Straight to flexuous chains of cylindrical spores are produced. Forms a white aerial mycelium and a reddish-brown substrate mycelium. Verticils are not present. The mycelium does not fragment. Diffusible pigments are produced on ISP 2, ISP 3, ISP 4, and ISP 5 media and on Gause's synthetic agar, but not on Czapek's solution agar. Melanin is produced on ISP 7. Although growth on ISP 4 is initially slow, very good growth with profuse sporulation is observed on this medium after 14 d. Very good growth occurs on ISP 2, Gause's synthetic agar, and ISP 3. Moderate growth is observed on ISP 5 but only poor growth on Czapek agar. The substrate mycelium is reddish brown on ISP 2, ISP 5, Gause's synthetic agar, ISP 4, and ISP 3, but grayish orange on Czapek medium. Utilizes melibiose, glucose, sorbinose, sucrose, D-fructose, xylose, D-galactose, rhamnose, and arabinose. Positive for production of H_2S, but pectin is not hydrolyzed. Cell wall contains LL-A_2pm (cell-wall type I). Whole-cell sugar pattern contains diagnostic sugars: mannose, small quantities of ribose and galactose. No antibiosis is exhibited against *Escherichia coli* ATCC 25922, *Pseudomonas aeruginosa* ATCC 6538, *Bacillus subtilis* ATCC 6633, *Candida albicans* ATCC 10231, or *Penicillium citrinum* AS 3.2788.

Type strain shows the highest sequence similarity to: *S. bikiniensis*, X79851, 99.5%; *S. violaceorectus*, AB184314, 99.4%; *S. viridobrunneus*, AJ781372, 99.1%; *S. tanashiensis*, AJ781362, 99%; *S. showdoensis*, AB184389, 99%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99%. Type strain shows DNA–DNA similarity to: *S. bikiniensis* ATCC 11062^T, 50.3%.

Source: the type strain was isolated from a forest soil sample in Vietnam.

DNA G+C content (mol%): 73.9.

Type strain: GIMV4.0001, CCTCC M 205143, IAM 15340, JCM 21785.

Sequence accession no. (16S rRNA gene): DQ311081.

496. **Streptomyces vinaceus** Jones 1952, 47[AL] emend. Lanoot, Vancanneyt, Dawyndt, Cnockaert, Zhang, Huang, Liu and Swings 2005a, 8 (Effective publication: Lanoot, Vancanneyt, Dawyndt Cnockaert, Zhang, Huang, Liu and Swings 2004, 90.)

vi.na′ce.us. L. masc. adj. *vinaceus* of or belonging to wine or the grape, referring to the color of the aerial mycelium.

Spore chains in Section *Retinaculiaperti* or *Spirales.* Primitive spirals or open imperfect spirals as well as hooks and loops of wide diameter are common. Mature spore chains are generally long, often with more than 50 spores

per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (4gc or 4ec, grayish yellowish pink; 5gc, light reddish brown; 5dc, grayish yellowish pink; 5ca, light yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; white aerial mycelium may be also present on glycerol-asparagine agar. Reverse side of colony is strong brown or orange brown on yeast-malt agar; orange yellow, yellowish brown, or grayish yellowish pink on oatmeal agar and salts-starch agar; grayish yellow to moderate yellowish pink on glycerol-asparagine agar. Reverse mycelium pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tryptone-yeast broth, and Gause's medium no. 2, but not in tyrosine agar. No pigment (or only a trace of yellow or pink) is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, D-mannitol, and D-fructose are utilized for growth. Utilization of L-arabinose is doubtful or weak. No growth or only traces of growth with D-xylose, iso-inositol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. cirratus*, AY999794, 100%; *S. sporoarveus*, AJ781370, 99.9%; *S. nojiriensis*, AJ781355, 99.9%; *S. xanthophaeus*, DQ442560, 99.8%; *S. sporoverrucosus*, DQ442544, 99.7%; *S. colombiensis*, DQ026646, 99.7%; *S. goshikiensis*, EF178693, 99.7%; *S. cinnamonensis*, AB184707, 99.6%; *S. avidinii*, AB184395, 99.6%; *S. subrutilus*, X80825, 99.5%; *S. virginiae*, D85119, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27476, CBS 726.72, BCRC 11865, DSM 40515, HUT 6082, NBRC 13425, JCM 4090, JCM 4849, KCTC 9771, NRRL 2382, NRRL-ISP 5515, PCM 2366, RIA 1386, RIA 805.

Sequence accession no. (16S rRNA gene): AB184394.

Further comments: according to Lanoot et al. (2004), *Streptomyces vinaceus* Jones 1952 is an earlier heterotypic synonym of *Streptomyces arabicus* Shibata et al. 1957.

497. **Streptomyces vinaceusdrappus** Pridham, Hesseltine and Benedict 1958, 68[AL]

vi.na.ce.us.drap′pus. L. adj. *vinaceus* of or belonging to wine or the grape; L. n. *drappus* a sheet, here referring to the color "drab"; N.L. masc. adj. *vinaceusdrappus* of wine-drab, referring to the drab wine color of the aerial mycelium and spores of the organism.

Spore chains in Section *Spirales*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red color series (5dc, grayish yellowish pink to 4ge, light grayish reddish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. One observer places this strain in the Gray color series (5fe, light grayish reddish brown or 3fe, light brownish gray). Reverse side of colony with no distinctive pigments (grayish yellow to yellowish or olive-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. rochei*, AB184237, 100%; *S. ghanaensis*, AY999851, 100%; *S. geysiriensis*, DQ442501, 100%; *S. minutiscleroticus*, EF178696, 100%; *S. plicatus*, AB184291, 100%; *S. mutabilis*, EF178679, 99.9%; *S. tuirus*, AB184690, 99.5%; *S. djakartensis*, AB184657, 99.4%; *S. anandii*, AB184402, 99.2%; *S. violaceorubidus*, AJ781374, 99.2%; *S. pilosus*, AB184161, 99.1%; *S. flavoviridis*, AB184842, 99.1%; *S. tendae*, D63873, 99%; *S. calvus*, AB184329, 99%; *S. azureus*, EF178674, 99%; *S. asterosporus*, AB184706, 99%; *S. levis*, AB184670, 99%; *S. luteogriseus*, AB184379, 99%; *S. capillispiralis*, AB184577, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 25511, CBS 653.69, BCRC 12170, DSM 40470, NBRC 13099, JCM 4529, NCIMB 12980, NRRL 2363, NRRL-ISP 5470, RIA 1291, VKM Ac-1902.

Sequence accession no. (16S rRNA gene): AY999929.

498. **Streptomyces violaceochromogenes** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham 1970, 28[AL] ["*Actinomyces violaceus chromogenes*" Krasil'nikov 1949, 55; "*Actinomyces violaceochromogenes*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 183; "*Actinomyces violochromogenes*" (*sic*) Artamonova and Krasil'nikov *in* Rautenshtein 1960, 334]

vi.o.la.ce.o.chro.mo′ge.nes. L. adj. *violaceus* violet; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *violaceochromogenes* producing violet color.

Spore chains in Section *Retinaculiaperti* or *Spirales*. Short chains form incomplete or imperfect spirals, hooks, flexuous chains. These are neither typically spiral nor representative of the long chains with open loops and spirals on true *Retinaculiaperti* cultures. Some longer chains bear terminal spirals suggesting *Retinaculiaperti* morphology. Mature spore chains are generally short with 3–10, or sometimes more than 10, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red (5cb, grayish yellowish pink) or Gray (5fe, light grayish reddish brown) color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow to strong brown) on yeast-malt agar and salts-starch agar; but

yellow to yellow-brown may or may not be modified by red on oatmeal agar and glycerol-asparagine agar. If red reverse, mycelium pigment is present, it is pH-sensitive changing from red to violet or purple with addition of 0.05 M NaOH or from violet to red with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but only weakly or not at all in tyrosine agar. Yellow or yellow-brown pigment is found in the medium in yeast-malt agar and salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. collinus*, AB184123, 99.6%; *S. iakyrus*, AB184877, 99.5%; *S. griseorubens*, AB184139, 99.1%; *S. paradoxus*, AB184628, 99.1%; *S. griseoflavus*, AJ781322, 99.1%; *S. matensis*, AB184221, 99.1%; *S. variabilis*, DQ442551, 99%; *S. griseoincarnatus*, AJ781328, 99%; *S. labedae*, AB184704, 99%; *S. erythrogriseus*, AJ781328, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19932, ATCC 25512, CBS 654.69, DSM 40181, NBRC 13100, INA 425, JCM 4530, NRRL B-5427, NRRL-ISP 5181, RIA 1292, VKM Ac-581.

Sequence accession no. (16S rRNA gene): AY999867.

499. **Streptomyces violaceolatus** (Krasil'nikov, Sorokina, Alferova and Bezzubenkova *in* Krasil'nikov 1965) Pridham 1970, 28[AL] ("*Actinomyces violaceolatus*" Krasil'nikov, Sorokina, Alferova and Bezzubenkova *in* Krasil'nikov 1965, 113)

vi.o.la.ce.o.la′tus. L. adj. *violaceus* violet-colored; L. adj. *latus* broad; N.L. masc. adj. *violaceolatus* violet, broad.

Forms blue-, purple-, or red-colored vegetative mycelium and diffusible pigment depending upon pH.

Spore chains in Section *Spirales*. Mature spore chains are long, usually with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray; 5fe, light grayish reddish brown; or 3ge, light grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Color may sometimes approach tab 5dc, grayish yellowish pink in the Red color series on glycerol-asparagine agar. Reverse side of colony is blue, purple, or red, depending upon pH and ranging from grayed colors to almost black, depending upon intensity of pigment. Reverse mycelium pigment is not a pH indicator, changing from red or violet to blue with addition of 0.05 M NaOH and from blue or violet to red or pink with addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Blue, violet, or red pigment, depending upon pH, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive, showing the same changes noted for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth, but growth on sucrose may be somewhat less than on any other carbon sources.

Type strain shows the highest sequence similarity to: *S. coelescens*, AF503496, 100%; *S. humiferus*, AF503491, 100%; *S. violaceoruber*, AF503492, 100%; *S. tricolor*, AB184687, 99.8%; *S. anthocyanicus*, AB184631, 99.8%; *S. rubrogriseus*, AB184681, 99.7%; *S. tendae*, D63873, 99.5%; *S. lienomycini*, AJ781353, 99.5%; *S. violaceorubidus*, AJ781374, 99.3%; *S. coelicoflavus*, AB184650, 99.3%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 19847, ATCC 25513, CBS 655.69, DSM 40438, ICSSB 1022, NBRC 13101, JCM 4531, KCTC 9772, NRRL B-12371, NRRL-ISP 5438, RIA 1293, VKM Ac-582.

Sequence accession no. (16S rRNA gene): AF503497.

500. **Streptomyces violaceorectus** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 63[AL] ("*Actinomyces violaceorectus*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 182)

vi.o.la.ce.o.rec′tus. L. adj. *violaceus* violet colored; L. adj. *rectus* straight; N.L. adj. *violaceorectus* violet colored, straight (referring to the color of the vegetative mycelium and diffusible pigment on some media and to the structure of sporophores).

Spore chains in Section *Rectiflexibiles*. Mature spore chains are generally long and straight, often with more than spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar (representative color tab from the Gray color series is 5fe, light grayish reddish brown; representative tabs from the Red color series are 5dc, 5ec, or 6ec, grayish yellowish pink). Reverse side of colony is grayish yellow to brown or grayish reddish brown on yeast-malt agar; yellowish pink or reddish brown to dark purplish pink or dark purplish red on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator, changing from orange or pink to violet or purple with addition of 0.05 M NaOH and from violet to pink or orange with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. Traces of yellow to pinkish brown pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Pink or pinkish brown pigment, when present, is pH-sensitive, changing from pink or brown to pale violet or gray with addition of 0.05 M NaOH.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. Limited growth also may occur on D-fructose and

sucrose. No growth or only trace of growth with iso-inositol, D-mannitol, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. bikiniensis*, X79851, 99.7%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99.7%; *S. vietnamensis*, DQ311081, 99.4%; *S. tanashiensis*, AJ781362, 99.2%; *S. nashvillensis*, AB184286, 99.2%; *S. showdoensis*, AB184389, 99.1%; *S. viridobrunneus*, AJ781372, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25514, CBS 656.69, BCRC 13626, DSM 40279, NBRC 13102, IMET 43520, INA 506, JCM 4532, NRRL B-12181, NRRL-ISP 5279, RIA 1294, VKM Ac-584.

501. **Streptomyces violaceoruber** (Waksman and Curtis 1916) Pridham 1970, 44[AL] ("*Actinomyces violaceus-ruber*" Waksman and Curtis 1916, 127; "*Streptomyces violaceoruber*" Waksman *in* Kutzner and Waksman 1959, 535)

vi.o.la.ce.o.ru′ber. L. adj. *violaceus* violet; L. adj. *ruber* red; N.L. masc. adj. *violaceoruber* violet-red.

Spore chains in Section *Spirales*, but spore chains representative of Sections *Rectiflexibiles* and *Retinaculiaperti* are also reported. Mature spore chains generally have 10–50 spores per chain. Typical morphology on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is blue or violet, depending on pH, on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse pigment is a pH indicator changing from violet or blue-violet to blue by addition of 0.05 M NaOH and from violet to red-violet or red with 0.05 M HCl.

Color in medium: melanoid pigments not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast extract broth. Blue or violet pigment found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive; color changes are identical to changes noted for reverse color.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only trace of growth on sucrose. Variable reports on growth with raffinose.

Type strain shows the highest sequence similarity to: *S. violaceolatus* AF503497, 100%; *S. coelescens*, AF503496, 100%; *S. humiferus*, AF503491, 100%; *S. tricolor*, AB184687, 99.9%; *S. anthocyanicus*, AB184631, 99.9%; *S. rubrogriseus*, AB184681, 99.7%; *S. tendae*, D63873, 99.6%; *S. lienomycini*, AJ781353, 99.6%; *S. violaceorubidus*, AJ781374, 99.4%; *S. coelicoflavus*, AB184650, 99.3%; *S. ambofaciens*, M27245, 99%; *S. pactum*, AB184398, 99%.

Sequence accession no. (16S rRNA gene): AF503492.

502. **Streptomyces violaceorubidus** Terekhova 1986, 575[VP] (Effective publication: Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

vi.o.la.ce.o.ru′bi.dus. L. adj. *violaceus* violet; L. adj. *rubidus* dark-red; N.L. masc. adj. *violaceorubidus* violet, dark-red.

Spore chains are spiral (*Spirales*); spores are smooth. On mineral agar 1: aerial mycelium is light gray; substrate mycelium and diffusible pigment are light pink, reddish violet; diffusible pigment is weak. On starch-ammonia agar: no aerial mycelium; substrate mycelium is yellow; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is creamy, light pinkish gray; substrate mycelium and diffusible pigment are yellowish reddish to violet red. On glycerol-asparagine agar: aerial mycelium is white, light gray; substrate mycelium is dark yellow; no diffusible pigment. On oatmeal agar: aerial mycelium is light pinkish gray; substrate mycelium and diffusible pigment are yellowish red to reddish violet; diffusible pigment is weak. On organic agar 2: aerial mycelium not extant or light gray, poor; substrate mycelium is yellowish; diffusible pigment is yellowish or not extant. On organic agar 79: aerial mycelium is light gray; substrate mycelium is yellowish; diffusible pigment is yellowish or not extant. Melanoid pigments are not formed. Good growth on rhamnose, fructose, glucose, xylose, mannitol, inositol, raffinose, and arabinose; sucrose is not utilized. Antibiotic: zinerubin.

Type strain shows the highest sequence similarity to: *S. tendae*, D63873, 99.8%; *S. lienomycini*, AJ781353, 99.7%; *S. rubrogriseus*, AB184681, 99.7%; *S. tricolor*, AB184687, 99.5%; *S. anthocyanicus*, AB184631, 99.5%; *S. matensis*, AB184221, 99.4%; *S. violaceoruber*, AF503492, 99.4%; *S. coelescens*, AF503496, 99.4%; *S. geysiriensis*, DQ442501, 99.3%; *S. minutiscleroticus*, EF178696, 99.3%; *S. humiferus*, AF503491, 99.3%; *S. violaceolatus* AF503497, 99.3%; *S. rochei*, AB184237, 99.2%; *S. ghanaensis*, AY999851, 99.2%; *S. malachitospinus*, AB249954, 99.2%; *S. vinaceusdrappus*, AY999929, 99.2%; *S. mutabilis*, EF178679, 99.2%; *S. plicatus*, AB184291, 99.2%; *S. lomondensis*, AB184673, 99.1%; *S. parvulus*, AB184326, 99.1%; *S. paradoxus*, AB184628, 99.1%; *S. griseorubens*, AB184139, 99.1%; *S. pactum*, AB184398, 99%; *S. malachitofuscus*, AB184282, 99%; *S. griseoflavus*, AJ781322, 99%; *S. tuirus*, AB184690, 99%; *S. variabilis*, DQ442551, 99%; *S. labedae*, AB184704, 99%; *S. griseoincarnatus*, AJ781328, 99%; *S. erythrogriseus*, AJ781328, 99%; *S. coelicoflavus*, AB184650, 99%; *S. viridochromogenes*, DQ442555, 99%; *S. collinus*, AB184123, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 43697, DSM 41478, NBRC 15463, INA 770, JCM 6931, NRRL B-16381, VKM Ac-1292.

Sequence accession no. (16S rRNA gene): AJ781374.

503. **Streptomyces violaceus** (Rossi Doria 1891) Waksman *in* Waksman and Lechevalier 1953, 43[AL] emend. Lanoot, Vancanneyt, Cleenwerk, Wang, Li, Liu and Swings 2002, 828 ["*Streptotrix* (*sic*) *violacea*" Rossi Doria 1891, 411; "*Oospora violacea*" Sauvageau and Radais 1892, 252; "*Actinomyces violaceus*" Gasperini 1894, 84; "*Cladothrix violacea*" Macé 1897, 1032; "*Nocardia violacea*" Chalmers and Christopherson 1916, 270].

vi.o.la′ce.us. L. masc. adj. *violaceus* violet colored, referring to the color of the vegetative mycelium and diffusible pigment of the organism.

Spore chains in Section *Spirales*. Mature spore chains are moderately long with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red color series (5cb, grayish yellowish pink or 7ca, light yellowish pink) on salts-starch agar and glycerol-asparagine agar; White or Red on yeast-malt agar; White color series on oatmeal agar. When aerial mycelium is thin, the red to violet color of the substrate mycelium may be evident. Reverse side of colony is reddish orange to purplish pink or pale purple, depending on pH. Reverse mycelium pigment is a pH indicator, changing from red to violet (purple) with addition of 0.05 M NaOH or from violet to red (pink) with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but not in tyrosine agar. Red or violet pigment, depending on pH, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive showing the same changes noted for the reverse mycelium pigments.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. roseoviolaceus*, AJ399484, 100%; *S. janthinus*, AB184851, 100%; *S. albosporeus* subsp. *albosporeus*, AJ781327, 100%; *S. luteogriseus*, AB184379, 99.5%; *S. lomondensis*, AB184673, 99.3%; *S. hawaiiensis*, AB184143, 99.3%; *S. flavoviridis*, AB184842, 99.3%; *S. pilosus*, AB184161, 99.2%; *S. arenae*, AB249977, 99.2%; *S. africanus*, AY208912, 99.2%; *S. tuirus*, AB184690, 99.2%; *S. bellus*, AB184849, 99.1%; *S. mutabilis*, EF178679, 99.1%; *S. massasporeus*, AB184152, 99%; *S. afghaniensis*, AJ399483, 99%; *S. levis*, AB184670, 99%; *S. coerulescens*, AY999720, 99%; *S. parvulus*, AB184326, 99%; *S. coeruleorubidus*, AY999719, 99%.

DNA G+C content (mol%): not known.

Type strain: AS 4.1456, ATCC 15888, ATCC 25515, CBS 657.69, BCRC 11880, CCT 4833, CECT 3235, DSM 40082, NBRC 13103, IMET 43085, INMI 1, JCM 4533, LMG 20257, NRRL B-2869, NRRL-ISP 5082, RIA 1295, RIA 656, VKM Ac-510, VKM Ac-977.

Sequence accession no. (16S rRNA gene): AB184315.

Further comments: Streptomyces violaceus (Rossi Doria 1891) Waksman 1953 emend. Lanoot et al. 2002 is an earlier heterotypic synonym of *Streptomyces violatus* (Artamonova and Krasil'nikov 1960) Pridham 1970.

504. **Streptomyces violaceusniger** corrig. (Waksman and Curtis 1916) Pridham, Hesseltine and Benedict 1958, 63[AL] emend. Labeda and Lyons 1991b, 400 ["*Actinomyces violaceus-niger*" Waksman and Curtis 1916, 111; "*Streptomyces violaco-niger*" (*sic*) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 947]

vi.o.la.ce.us.ni′ger. L. adj. *violaceus* violet; L. adj. *niger* black; N.L. masc. adj. *violaceusniger* violet-black.

Spore chains are *Spirales*; the spore surface is smooth to rough. The spore mass is gray, becoming black and moist when it is mature. Reverse side of colonial growth is grayish yellow or light olive green to dark olive to dark grayish green. Melanoid pigments are not formed; soluble pigments are not produced. D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are utilized for growth. Exhibits anti-bacterial and anti-fungal activity; excellent growth on Czapek's solution agar; gray to black vegetative mycelium on some media; hygroscopic; NaCl tolerance >4%, but <7%.

Type strain shows the highest sequence similarity to: *S. yogyakartensis*, AB249942, 100%; *S. albiflaviniger*, AJ391812, 99.7%; *S. endus*, AY999911, 99.5%; *S. sporocinereus*, AB249933, 99.5%; *S. demainii*, DQ334782, 99.5%; *S. hygroscopius* subsp. *hygroscopius*, AB184428, 99.5%; *S. javensis*, AJ391833, 99.1%.

Source: not known.

DNA G+C content (mol%): 71.2.

Type strain: AS 4.1423, ATCC 27477, CBS 760.72, DSM 40563, NBRC 13459, JCM 4850, LMG 19336, NRRL B-1476, NRRL-ISP 5563, RIA 1420, VKM Ac-583.

Sequence accession no. (16S rRNA gene): AJ391823.

Further comments: the original spelling, *Streptomyces violaceoniger* (*sic*), has been corrected by Hill et al. (1984).

505. **Streptomyces violarus** (Artamonova and Krasil'nikov 1960) Pridham 1970, 30[AL] ("*Actinomyces violarus*" Artamonova and Krasil'nikov *in* Rautenshtein 1960, 334)

vi.o.la′rus. N.L. masc. adj. *violarus* (from L. adj. *violaris*) of or belonging to violets, violet, referring to the color of the vegetative mycelium.

Spore chains in Section *Spirales*. Spirals of three to four turns may be formed or poorly developed irregular spirals, hooks or loops may become entangled. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Red or Violet color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs are 5cb, 5ec or 6ec, grayish yellowish pink from the Red color series or 11ca, very pale purple, from the Violet color series. Reverse side of colony is reddish orange or reddish brown to purplish pink or purple depending upon pH. Reverse mycelium pigment is a pH indicator, changing from pink or violet to blue-violet or blue with addition of 0.05 M NaOH and from violet to pink or red with addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but only weakly or not at all in tyrosine agar. Red or violet pigment, depending upon pH, is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive, showing the same changed noted for reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows no sequence similarity over 99%.

Type strain: ATCC 15891, ATCC 25516, CBS 658.69, CCT 5007, CECT 3237, DSM 40205, NBRC 13104, INMI 1212, JCM 4534, KCTC 9788, NRRL B-5432, NRRL-ISP 5205, RIA 1296, RIA 157, UNIQEM 204, VKM Ac-528.

Sequence accession no. (16S rRNA gene): AB184316.

506. **Streptomyces violascens** (Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 68^{AL} ("*Actinomyces violascens*" Preobrazhenskaya and Sveshnikova *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 41)

vi.o.la′scens. N.L. part. adj. *violascens* becoming violet.

Spore chains in Section *Spirales*. Mature spore chains have 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Violet color series on salts-starch agar and glycerol-asparagine agar; Violet or White color series on oatmeal agar; Violet, White, or Red color series on yeast-malt agar. Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. Pigments other than melanoids not formed (or only traces of yellow) in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, and raffinose are utilized for growth. No growth or only trace of growth on D-mannitol and rhamnose. Utilization of sucrose and iso-inositol is doubtful.

Type strain shows the highest sequence similarity to: *S. limosus*, AB184147, 100%; *S. felleus*, AB184129, 100%; *S. daghestanicus*, DQ442497, 100%; *S. albidoflavus*, AB184255, 100%; *S. hydrogenans*, AB184868, 100%; *S. odorifer*, Z76682, 100%; *S. griseus* subsp. *solvifaciens*, AB249915, 100%; *S. champavatii*, DQ026642, 100%; *S. canescens*, AB184117, 100%; *S. sampsonii*, D63871, 99.8%; *S. koyangensis*, AY079156, 99.7%.

507. **Streptomyces violatus** (Artamonova and Krasil'nikov 1960) Pridham 1970, 30^{AL} ("*Actinomyces violatus*" Artamonova and Krasil'nikov *in* Rautenshtein 1960, 334)

vi.o.la′tus. L. masc. adj. *violatus* flavored with violet, referring to the color of the vegetative mycelium and diffusible pigment of the organism.

Spore chains in Section *Spirales*. Mature spore chains are moderately long, with 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the White or Red color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tab in the Red color series is 5cb, grayish yellowish pink. Reverse side of colony is light grayish reddish brown on yeast-malt agar; light reddish purple to dark purplish pink, or yellowish pink on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator, changing from red or pink to violet or blue with the addition of 0.05 M NaOH and from violet to yellowish pink or orange with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but appear slowly or not at all in tyrosine agar. Red to violet pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is pH-sensitive, showing the same changes recorded for the reverse mycelium pigment.

D-Glucose, L-arabinose, D-xylose, D-fructose, rhamnose, sucrose, raffinose, iso-inositol, and D-mannitol are all utilized for growth.

For sequence similarity, see type strain of *Streptomyces violaceus.*

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 15892, CBS 650.72, DSM 40209, NBRC 13349, INMI 1205, JCM 4237, JCM 4851, NRRL B-2867, NRRL-ISP 5209, RIA 708.

Sequence accession no. (16S rRNA gene): AJ399480.

Further comments: Streptomyces violatus (Artamonova and Krasil'nikov 1960) Pridham 1970 is a later heterotypic synonym of *Streptomyces violaceus* (Rossi Doria 1891) Waksman 1953 emend. Lanoot et al. 2002.

508. **Streptomyces violens** (Kalakoutskii and Krasil'nikov 1960) Goodfellow, Williams and Alderson 1987c, 179^{VP} (Effective publication: Goodfellow, Williams and Alderson 1986d, 59.) (*Chainia violens* Kalakoutskii and Krasil'nikov *in* Rautenshtein 1960, 55)

vi.o.lens. L. adj. *violens* raging but probably from L. fem. n. *viola* violet, referring to pink to violet pigment produced by the organism on some media.

Spore chain Section not determined. Aerial mycelium is not produced on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar. Spore surface not determined. Sclerotia are produced on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar, and the substrate (vegetative) mycelium fragments into rod-shaped or coccoid elements on these media. One observer reports L-A_2pm and the absence of arabinose in the cell wall (cell-wall type I).

Color of colony: aerial mass color not determined; aerial mycelium absent on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (colorless on

glycerol-asparagine agar; pale or grayish yellow to light olive on yeast-malt agar, oatmeal agar, and salts-starch agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. One observer reports that melanin is produced on a peptone-yeast-iron agar of different composition. A pale yellow pigment in oatmeal agar is reported by one observer; and another reports orange or pinkish pigment in glycerol-asparagine agar. The latter is pH-sensitive, changing from orange or rose to violet or light purple with the addition of 0.05 M NaOH.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose are all utilized for growth.

Type strain shows the highest sequence similarity to: *S. ochraceiscleroticus*, AB184094, 99.8%; *S. purpurogeneiscleroticus*, AJ621604, 99.7%; *S. monomycini*, DQ445790, 99.3%; *S. erumpens*, AJ621603, 99.1%.

Source: not known.

Sequence accession no. (16S rRNA gene): AJ621605.

509. **Streptomyces virens** Gause and Sveshnikova 1986a, 575[VP] (Effective publication: Gause and Sveshnikova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.)

vi′rens. L. part. adj. *virens* being green.

Spore chains are spiral (*Spirales*); spore surface has spines and warts, warts are situated between hairs and spines. On mineral agar 1: aerial mycelium is light gray to greenish, poorly developed; substrate mycelium is olive, gray brownish olive; diffusible pigment is orange red, moderate. On glycerol-nitrate agar: aerial mycelium is weak developed with white grayish appearance; substrate mycelium is olive, gray-brown olive; diffusible pigment is light brown. On starch-ammonia agar: aerial mycelium is poorly developed, whitish or grayish; substrate mycelium is colorless to light olive; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is absent or poorly developed with white appearance; substrate mycelium and diffusible pigment are olive. On oatmeal agar: aerial mycelium is absent or whitish; substrate mycelium is olive; no diffusible pigment. On organic agar 2: aerial mycelium is absent or whitish; substrate mycelium is gray brownish; diffusible pigment is reddish. Melanoid pigments are not formed. Moderate growth on arabinose, fructose, and mannitol; no growth on xylose, raffinose, rhamnose, sucrose, or cellulose. Antibiotic: virenomycin.

Type strain shows the highest sequence similarity to: *S. calvus*, AB184329, 99.9%; *S. aureorectus*, AB184710, 99.9%; *S. asterosporus*, AB184706, 99.8%; *S. djakartensis*, AB184657, 99%; *S. geysiriensis*, DQ442501, 99%; *S. tuirus*, AB184690, 99%; *S. anandii*, AB184402, 99%; *S. minutiscleroticus*, EF178696, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: DSM 41465, NBRC 15901, INA 3831, JCM 9095, NRRL B-24331, VKM Ac-833.

Sequence accession no. (16S rRNA gene): DQ442554.

510. **Streptomyces virginiae** Grundy, Whitman, Rdzok, Rdzok, Hanes and Sylvester 1952, 399[AL]

vir.gi.ni′a.e. N.L. gen. n. *virginiae* of Virginia, referring to the source of the soil (near Roanoke, Virginia) from which the organism was isolated.

Spore chains in Section *Retinaculiaperti*, including flexuous, looped, and spiral forms characteristic of this section (terminal spirals on long spore chains may be common in some areas on mass cultures). Mature spore chains are moderately long with 10–50, or sometimes more than 50, spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red or Gray color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Color tabs selected by observers: Grayish yellowish pink (5dc, 6ec, Red series), pale purple (7fe, Gray series). Reverse side of colony with no distinctive pigment (grayed yellow to yellow-brown) on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar; dark grayed yellow may be modified by traces of red or violet on salts-starch agar. Substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar or tryptone-yeast extract broth. Pigments other than melanoids are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose and D-fructose are utilized for growth. Trace of growth on L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, rhamnose, and raffinose is similar to, or only slight better than growth on basal medium without carbon.

Type strain shows the highest sequence similarity to: *S. cinnamonensis*, AB184707, 99.8%; *S. sporoaveus*, AJ781370, 99.5%; *S. nojiriensis*, AJ781355, 99.5%; *S. xanthophaeus*, DQ442560, 99.5%; *S. vinaceus*, AB184394, 99.4%; *S. goshikiensis*, EF178693, 99.4%; *S. cirratus*, AY999794, 99.4%; *S. avidinii*, AB184395, 99.3%; *S. subrutilus*, X80825, 99.3%; *S. sporoverrucosus*, DQ442544, 99.2%; *S. colombiensis*, DQ026646, 99.1%; *S. flavotricini*, AB184132, 99%.

Source: isolated from soil near Roanoke, Virginia, USA.

DNA G+C content (mol%): not known.

Type strain: ATCC 19817, CBS 291.60, CBS 570.68, BCRC 12069, DSM 40094, NBRC 12827, NBRC 3729, JCM 4425, KCTC 1747, NRRL B-1446, NRRL-ISP 5094, RIA 1097, UNIQEM 205, VKM Ac-1218.

Sequence accession no. (16S rRNA gene): D85119.

511. **Streptomyces viridiflavus** corrig. (Locci and Schofield 1989) Witt and Stackebrandt 1991, 457[VP] (Effective publication: Witt and Stackebrandt 1990, 370.) ["*Streptoverticillium viridoflavum*" (*ex* Waksman and Taber 1953) Locci 1985, 232; *Streptoverticillium viridoflavum* Locci and Schofield *in* Williams, Sharpe and Holt 1989, 2503]

vir.i.di.flav′us. L. adj. *viridis* green; L. adj. *flavus* yellow; N.L. masc. adj. *viridiflavus* green-yellow.

Poor off-white aerial vegetation. White spore mass. Melanin pigment is not produced. Coumarin, L-methionine, L-proline, and shikimic acid are utilized, but not mannitol, melibiose, raffinose, sorbitol, or DL-α-aminobutyric acid. Produces acid from *myo*-inositol, D-ribose, and trehalose, but not from D-galactose or D-fructose. Citrate and hypoxanthine are degraded, but not esculin or L-tyrosine. H_2S is produced. No reduction of NO_3^-. Resistance shown to cephalotin (30 μg/ml), colistin (30 μg/ml), and cephamandole (30 μg/ml). *Aspergillus niger* and *Candida albicans* are inhibited but not *Bacillus subtilis*. The strain shows antifungal activity.

For sequence similarity, see type strain of *Streptomyces olivoverticillatus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: Y. E. Konev, ATCC 12631, CBS 652.72, DSM 40237, NBRC 13351, NBRC 15799, JCM 4221, JCM 4857, NRRL B-1548, NRRL-ISP 5237, RIA 1312.

Sequence accession no. (16S rRNA gene): AB184702.

Further comments: in violation of Rule 33c of the *Bacteriological Code* (1990 Revision), in Validation List no. 38, *Streptomyces viridiflavus* corrig. is proposed as a *nomen revictum* (basonym: "*Streptomyces viridoflavum*" Waksman and Taber 1953).

The original spelling of the specific epithet, *viridoflavum* (*sic*), has been corrected by Euzéby (1998).

According to Hatano et al. (2003), *Streptomyces viridiflavus* corrig. (Locci and Schofield 1989) Witt and Stackebrandt 1991 is a later heterotypic synonym of *Streptomyces olivoverticillatus* (Shinobu 1956) Witt and Stackebrandt 1991.

512. **Streptomyces viridiviolaceus** (Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957) Pridham, Hesseltine and Benedict 1958, 70[AL] ("*Actinomyces viridiviolaceus*" Ryabova and Preobrazhenskaya *in* Gauze, Preobrazhenskaya, Kudrina, Blinov, Ryabova and Sveshnikova 1957, 188)

vi.ri.di.vi.o.la′ce.us. L. adj. *viridis* green; L. adj. *violaceus* violet-colored; N.L. masc. adj. *viridiviolaceus* green-violet, referring to the greenish color of the aerial mycelium and the violet color of diffusible pigment.

Spore chains in Section *Spirales*. Mature spore chains are moderately long, with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny to hairy.

Color of colony: aerial mass color in the Gray color series (3fe, light brownish gray; 5fe or 5ge, light grayish reddish brown; 3ig, grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony is strong brown or reddish brown on yeast-malt agar and glycerol-asparagine agar; yellowish brown or olive brown on oatmeal agar and salts-starch agar. Reverse mycelium pigment is a pH indicator, changing from yellow or orange to violet with the addition of 0.05 M NaOH and from violet or red to orange with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Orange or red pigment is found in the medium in yeast-malt agar, salts-starch agar, and glycerol-asparagine agar but not in oatmeal agar. This pigment is pH-sensitive, showing the same changes observed with the reverse mycelium pigment.

D-Glucose, L-arabinose, D-mannitol, and D-fructose are utilized for growth. Utilization of D-xylose, iso-inositol, and sucrose is doubtful. No growth or only traces of growth with rhamnose and raffinose.

Type strain shows the highest sequence similarity to: *S. levis*, AB184670, 99.2%; *S. cellulosae*, DQ442495, 99%; *S. gancidicus*, AB184660, 99%; *S. pseudogriseolus*, DQ442541, 99%.

DNA G+C content (mol%): not known.

Type strain: ATCC 27478, CBS 660.72, BCRC 12457, DSM 40280, NBRC 13359, INA 5276/56, JCM 4855, NRRL B-12182, NRRL-ISP 5280, RIA 1320, VKM Ac-587.

Sequence accession no. (16S rRNA gene): AY999854.

513. **Streptomyces viridobrunneus** (*ex* Krasil'nikov 1970b) Terekhova 1986, 575[VP] (Effective publication: Terekhova *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces viridobrunneus*" Krasil'nikov 1970b)

vi.ri.do.brun′ne.us. L. adj. *viridis* green; N.L. adj. *brunneus* dark brown; N.L. masc. adj. *viridobrunneus* green dark-brown colored.

Spore chains are straight to flexuous (*Rectiflexibiles*); spores are smooth. On mineral agar 1: aerial mycelium is gray; substrate mycelium is brownish greenish olive gray; diffusible pigment is green to olive. On glycerol-nitrate agar: aerial mycelium is absent or white, poorly developed; substrate mycelium and diffusible pigment are gray brownish olive to olive gray brown. On starch-ammonia agar, glycerol-asparagine agar: aerial mycelium is absent or gray, gray brownish gray; substrate mycelium is gray brownish green; diffusible pigment is green, gray brownish green. On oatmeal agar: aerial mycelium is gray; substrate mycelium is yellowish to olive; no diffusible pigment. On organic agar 2: aerial mycelium is gray; substrate mycelium and diffusible pigment are dark gray brown. Melanoid pigments are formed. Glucose, mannose, sucrose, and raffinose are utilized for growth; no growth on mannitol, rhamnose, inositol, or arabinose. Antibiotic: pigment antibiotic viridomycin. The type strain is characterized by gray aerial mycelium, straight spore chains, building melanoid pigment and having green to olive gray brownish color of substrate mycelium and diffusible pigment under the pigment viridomycin.

Type strain shows the highest sequence similarity to: *S. showdoensis*, AB184389, 100%; *S. cinereoruber* subsp. *cinereoruber*, AB184121, 99.4%; *S. roseoviridis*, AB184239, 99.4%; *S. nashvillensis*, AB184286, 99.1%; *S. tanashiensis*, AJ781362, 99.1%; *S. vietnamensis*, DQ311081, 99.1%; *S. violaceorectus*, AB184314, 99%; *S. bikiniensis*, X79851, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 43698, DSM 41466, NBRC 15902, INMI 300, JCM 9096, VKM Ac-559.

Sequence accession no. (16S rRNA gene): AJ781372.

514. **Streptomyces viridochromogenes** (Krainsky 1914) Waksman and Henrici 1948, 942[AL] ("*Actinomyces viridochromogenes*" Krainsky 1914, 684)

vi.ri.do.chro.mo′ge.nes. L. adj. *viridis* green; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *viridochromogenes* producing green color.

Spore chains in Section *Spirales*. Mature spore chains are generally long, often with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Green color series (24ih, grayish green; 24½h, dark grayish green), Yellow color series (24½dc, pale yellow green) or Gray color series (2dc, yellowish gray) on yeast-malt agar. It is in the Yellow (1dc, pale yellow green), Green (24½li, dark greenish gray), or Blue (22fe, pale green) color series on oatmeal agar. It is in the Blue (19dc, pale blue; 22fe, pale green) color series on salts-starch agar. It is in the Blue (19dc, pale blue; 22fe, pale green) or Yellow (1dc, pale yellow green) color series on glycerol-asparagine agar. Reverse side of colony is olive brown to dark olive on yeast-malt agar; grayish green to grayish olive on oatmeal agar; grayish yellow, olive brown, or greenish yellow on salts-starch agar and glycerol-asparagine agar. Reverse mycelium pigment is a pH indicator, changing from bluish or greenish brown to reddish or purplish brown with the addition of 0.05 M HCl.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar or tryptone-yeast broth; tyrosine agar may or may not be darkened in 2–4 d. Greenish pigment is found in the medium in oatmeal agar. This pigment is pH-sensitive, changing from blue green or greenish to pink with the addition of 0.05 M HCl.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. Utilization of sucrose is doubtful.

Type strain shows the highest sequence similarity to: *S. paradoxus*, AB184628, 99.4%; *S. matensis*, AB184221, 99.3%; *S. collinus*, AB184123, 99.3%; *S. griseoflavus*, AJ781322, 99.2%; *S. griseorubens*, AB184139, 99.2%; *S. flaveolus*, AB184764, 99.2%; *S. griseoincarnatus*, AJ781328, 99.1%; *S. labedae*, AB184704, 99.1%; *S. erythrogriseus*, AJ781328, 99.1%; *S. violaceorubidus*, AJ781374, 99%; *S. glaucescens*, AB184843, 99%; *S. variabilis*, DQ442551, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 14920, CBS 140.20, CBS 648.72, BCRC 13769, CECT 3216, DSM 40110, HAMBI 1023, HUT 6030, NBRC 13347, NBRC 3113, JCM 4265, JCM 4856, NCIMB 9597, NRRL B-1511, NRRL-ISP 5110, RIA 1308, VKM Ac-629.

Sequence accession no. (16S rRNA gene): DQ442555.

515. **Streptomyces viridodiastaticus** (Baldacci, Grein and Spalla 1955) Pridham, Hesseltine and Benedict 1958, 67[AL] ["*Actinomyces virido-diastaticus*" (*sic*) Baldacci, Grein and Spalla 1955, 133]

vi.ri.do.di.a.sta′ti.cus. L. adj. *viridis* green; N.L. adj. *diastaticus*, diastatic, starch, digesting; N.L. masc. adj. *diastaticus* green-diastatic.

Spore chains in Section *Spirales* but abundant open spirals and flexuous chains also suggest *Retinaculiaperti* morphology. Spirals are most abundant on salts-starch agar. Mature spore chains are moderately long with 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny, but spines may not be apparent on some spores.

Color of colony: aerial mass color in the Gray color series (2fe, medium gray to 2ih, light olive-gray or 3ig, grayish yellowish brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (yellowish brown to olive-brown on yeast-malt agar; pale yellow-green or pale yellow and grayish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on utilization of sucrose and raffinose.

Type strain shows the highest sequence similarity to: *S. albogriseolus*, AJ494865, 99.8%; *S. coeruleorubidus*, AY999719, 99.4%; *S. bellus*, AB184849, 99.2%; *S. griseorubens*, AB184139, 99.2%; *S. coerulescens*, AY999720, 99.2%; *S. atrovirens*, DQ026672, 99.2%; *S. iakyrus*, AB184877, 99.1%; *S. longispororuber*, AB184440, 99.1%; *S. variabilis*, DQ442551, 99%; *S. erythrogriseus*, AJ781328, 99%; *S. lusitanus*, AB184424, 99%; *S. labedae*, AB184704, 99%; *S. speibonae*, AF452714, 99%; *S. griseoincarnatus*, AJ781328, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 25518, CBS 660.69, BCRC 12458, DSM 40249, NBRC 13106, JCM 4536, NRRL B-5622, NRRL-ISP 5249, RIA 1298, VKM Ac-1749.

Sequence accession no. (16S rRNA gene): AY999852.

516. **Streptomyces viridosporus** Pridham, Hesseltine and Benedict 1958, 67[AL]

vi.ri.do.spo′rus. L. adj. *viridis* green; N.L. n. *spora* a spore; N.L. masc. adj. *viridosporus* green-spored.

Spore chains in Section *Spirales*. Spirals are sometimes irregular or imperfect when spore chains are short. Mature spore chains are generally short but contain more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny to hairy.

Color of colony: aerial mass color in the Green color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Three observers selected a variety of color tabs as the nearest matching color including: 2ih, light olive; 1½li, olive gray; 1½ge, 1½ig, 1ig, light grayish olive; and 24½ih, dark greenish gray. Reverse side of colony with no distinctive pigments (yellowish brown to olive brown on yeast-malt agar; pale grayish yellow to light yellowish brown or grayish olive on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth in 2–4 d. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. No growth or only traces of growth with sucrose or raffinose.

Type strain shows no sequence similarity over 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27479, CBS 654.72, BCRC 11870, CCUG 37512, DSM 40243, NBRC 13353, IMET 43514, JCM 4859, KCTC 9145, NCIMB 9824, NRRL 2414, NRRL-ISP 5243, RIA 1314, VKM Ac-1769, VKM Ac-618.

Sequence accession no. (16S rRNA gene): DQ442556.

517. **Streptomyces vitaminophilus** corrig. (Shomura, Amano, Yoshida, Ezaki, Ito and Niida 1983) Goodfellow, Williams and Alderson 1986a, 575[VP] (Effective publication: Goodfellow, Williams and Alderson 1986e, 63.) (*Actinosporangium vitaminophilum* Shomura, Amano, Yoshida, Ezaki, Ito and Niida 1983, 563)

vi.ta.mi.no′phi.lus. N.L. n. *vitaminum* vitamin; N.L. masc. adj. *philus* (from Gr. masc. adj. *philos*) friend, loving; N.L. masc. adj. *vitaminophilus* vitamin-loving.

Spores contained in "pseudosporangia"; the spore surface is smooth. Forms extensively branched substrate mycelium but scant aerial mycelium. The reverse side of colonies is colorless to pale tan or pale grayish yellow. Growth is often enhanced by vitamin B_{12}. Does not form melanin pigments. Gelatin and starch degraded; nitrate is reduced. D-Glucose, glycerol, L-rhamnose, and D-xylose are used as sole carbon sources but L-arabinose, D-fructose, *myo*-inositol, mannitol, raffinose, and sucrose are not. Grows at 15 and 45°C; optimal growth between 25 and 34°C. Wall peptidoglycan contains LL-A_2pm as the major diamino acid; the predominant isoprenologs are hexa- and octa-hydrogenated menaquinones with nine isoprene units. Produces antibiotics of the pyrrolomycin complex.

Type strain shows no sequence similarity over 99%.

Source: isolated from soil.

DNA G+C content (mol%): not known.

Type strain: SF 2080, ATCC 31673, DSM 41686, NBRC 14294, JCM 6054, NRRL B-16933.

Sequence accession no. (16S rRNA gene): AB184589.

Further comments: the original spelling, *Streptomyces vitaminophileus* (*sic*), has been corrected by the Associate Editor, IJSB 1986.

518. **Streptomyces wedmorensis** (*ex* Millard and Burr 1926) Preobrazhenskaya 1986, 575[VP] (Effective publication: Preobrazhenskaya *in* Gause, Preobrazhenskaya, Sveshnikova, Terekhova and Maximova 1983.) ("*Actinomyces wedmorensis*" Millard and Burr 1926)

wed.mor.en′sis. N.L. masc. adj. *wedmorensis* of or pertaining to Wedmore, a city in England.

Spore chains are straight (*Rectiflexibiles*); spores are smooth. On mineral agar 1, oatmeal agar, and starch-ammonia agar: aerial mycelium is whitish gray to gray; substrate mycelium is colorless; no diffusible pigment. On glycerol-nitrate agar: aerial mycelium is poor, white; substrate mycelium yellow; no diffusible pigment. On organic agar 2: aerial mycelium is poor, white; substrate mycelium colorless; no diffusible pigment. On glycerol-asparagine agar: aerial mycelium is poor, white; substrate mycelium light gray-brown; no diffusible pigment. Melanoid pigments are not formed. Good growth on glucose, xylose, mannitol, and fructose; poor growth on arabinose and rhamnose. Antibiotic: phosphonomycin, antibiotic 280.

Type strain shows the highest sequence similarity to: *S. exfoliatus*, AB184324, 99.7%; *S. zaomyceticus*, EF178685, 99.7%; *S. venezuelae*, AB045890, 99.7%; *S. omiyaensis*, EF178697, 99.6%; *S. lateritius*, AB184324, 99.6%; *S. litmocidini*, AB184149, 99.5%; *S. yereyanensis* EF178684, 99.3%; *S. narbonensis*, DQ445794, 99.2.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 21239, BCRC 12667, CECT 3245, DSM 41676, ICMP 12544, NBRC 14062, JCM 4937, NRRL 3426, VKM Ac-1861.

Sequence accession no. (16S rRNA gene): DQ442557.

519. **Streptomyces werraensis** Wallhäusser, Huber, Nesemann, Präve and Zepf 1964, 357[AL]

wer.ra.en′sis. N.L. masc. adj. *werraensis* of or belonging to River Werra, Germany (referring to "werramycin," the name originally assigned to the antibiotics produced).

Spore chains in Section *Spirales* or *Retinaculiaperti*. Imperfect spirals, flexuous chains, hooks, and loops are common; well-developed spirals are rare. Mature spore chains generally contain 10 to 50 or more spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is spiny.

Color of colony: aerial mass color in the Gray color series (2dc, yellowish gray; 3fe, light brownish gray; g or e, medium gray) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Aerial mycelium is sometimes absent or poorly developed on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (nearly colorless or pale yellowish gray on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment is found in the medium in

yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, and rhamnose are utilized for growth. Reports vary on amount of growth on sucrose, but utilization is doubtful. No growth or only traces of growth with raffinose.

Type strain shows the highest sequence similarity to: *S. biverticillatus*, AJ781381, 100%; *S. albireticuli*, AB184881, 99.5%; *S. netropsis*, AB184848, 99.3%; *S. eurocidicus*, AY999790, 99.3%; *S. cinnamoneus*, AB184850, 99.1%; *S. hiroshimensis*, AB184789, 99%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 14424, CBS 437.67, CBS 705.72, BCRC 12038, DSM 40486, NBRC 13404, JCM 4860, NRRL B-5317, NRRL-ISP 5486, RIA 1365.

Sequence accession no. (16S rRNA gene): DQ442558.

520. **Streptomyces willmorei** (Erikson 1935) Waksman and Henrici *in* Breed, Murray and Hitchens 1948, 966[AL] ["*Actinomyces willmorei*" Erikson 1935, 36; *Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948, 950 emend. Lanoot, Vancanneyt, Van Shoor, Liu and Swings 2005b, 731]

will.mo′re.i. N.L. gen. masc. n. *willmorei* of Willmore, named for J.G. Willmore, the surgeon who first isolated the organism.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are short to moderately long, usually with more than 10 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray, Yellow, or White color series on yeast-malt agar, oatmeal agar, and salts-starch agar; White or Yellow color series on glycerol-asparagine agar. Nearest matching color tabs in the Gray color series are d, medium gray, and 2dc, yellowish gray. Nearest matching color tabs in the Yellow color series are 2ba and 2db, pale yellow. Reverse side of colony with no distinctive pigments (light olive brown or yellowish brown on yeast-malt agar; colorless to pale grayish yellow or light grayish olive on oatmeal agar, salts-starch agar, and glycerol-asparagine agar).

Color in medium: melanoid pigments are not formed (or only a very weak discoloration occurs) in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. No pigment or only a trace of yellow is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, D-xylose, D-mannitol, D-fructose, and rhamnose are utilized for growth. Utilization of L-arabinose is doubtful. No growth or only traces of growth with iso-inositol, sucrose, and raffinose.

For sequence similarity, see type strain of *Streptomyces microflavus*.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 6867, CBS 372.64, CBS 692.72, BCRC 12640, DSM 40459, NBRC 13391, IMET 41387, JCM 4861, 21046, NCIMB 12984, NCTC 1856, NRRL B-1332, NRRL-ISP 5459, RIA 1352, VKM Ac-1867.

Sequence accession no. (16S rRNA gene): AB184374.

Further comments: according to Lanoot et al. (2005b), *Streptomyces willmorei* (Erikson 1935) Waksman and Henrici 1948 is a later heterotypic synonym of *Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948 emend. Lanoot et al. 2005b.

521. **Streptomyces xanthochromogenes** Arishima, Sakamoto and Sato 1956, 469[AL]

xan.tho.chro.mo′ge.nes. Gr. adj. *xanthos* yellow; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *xanthochromogenes* producing yellow color.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally have 10–50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Yellow color series on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinct pigment (yellow, grayed yellow, or yellow-brown) on yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar; substrate pigment is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast extract broth. Yellow pigment may be found in oatmeal agar and salts-starch agar or may be absent. Yellow pigment is not pH-sensitive.

D-Glucose, D-xylose, D-mannitol, and D-fructose are utilized for growth. Only trace of growth indicating doubtful utilization of iso-inositol, rhamnose, and raffinose. Variable reports on growth with L-arabinose and sucrose.

Type strain shows the highest sequence similarity to: *S. michiganensis*, AB184153, 100%; *S. mauvecolor*, AB184532, 99.4%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1435, ATCC 19818, CBS 571.68, BCRC 11876, DSM 2015, DSM 40111, NBRC 12828, JCM 4215, JCM 4612, NRRL B-5410, NRRL-ISP 5111, RIA 1098, UNIQEM 207, VKM Ac-1071.

Sequence accession no. (16S rRNA gene): DQ442559.

522. **Streptomyces xanthocidicus** Nagatsu, Asahi and Suzuki in Asahi, Nagatsu and Suzuki 1966, 196[AL]

xan.tho.ci′di.cus. Gr. adj. *xanthos* yellow; L. v. *caedo* to kill; N.L. masc. adj. *xanthocidicus* pertaining to yellow and to cut, probably referring to the name given the antibiotic produced which, in turn, was probably derived from its activity against *Xanthomonas oryzae*.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally are long and straight with more than 50 spores per chain. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series (5fe, light grayish reddish brown; 3fe, light brownish

gray; d-2fe, light to moderate gray) on yeast-malt agar, oatmeal agar, salts-starch agar, glycerol-asparagine agar, and Gause's medium no. 1. Reverse side of colony with no distinctive pigments (colorless to pale grayish yellow on glycerol-asparagine agar; grayish yellow on oatmeal agar and salts-starch agar; light yellowish brown to brown on yeast-malt agar and Gause's medium no. 1).

Color in medium: melanin reaction variable in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth; both weakly positive and negative reactions are recorded by different observers in 2–4 d. No pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, or glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, D-fructose, sucrose, and raffinose are utilized for growth. No growth or only traces of growth with iso-inositol, D-mannitol, and rhamnose.

Type strain shows the highest sequence similarity to: *S. purpureus*, AJ781324, 99.5%; *S. aburaviensis*, AY999779, 99.4,%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.4%; *S. herbaricolor*, AB184801, 99.2%; *S. indigoferus*, AB184214, 99.2%; *S. aureofaciens*, AY207608, 99.1%; *S. psammoticus*, AY999862, 99%. Type strain shows the highest sequence similarity to following *Kitasatospora* species: *Kitasatospora kifunensis*, AB022874, 99.1%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: AS 4.1424, ATCC 27480, CBS 770.72, BCRC 11874, DSM 40575, NBRC 13469, JCM 4243, JCM 4862, NRRL B-12504, NRRL-ISP 5575, RIA 1430, VKM Ac-872.

Sequence accession no. (16S rRNA gene): AY999858.

523. **Streptomyces xantholiticus** (Konev and Tsyganov 1962) Pridham 1970, 31[AL] ["*Actinomyces xantholiticus*" (*sic*) Konev and Tsyganov 1962, 1026]

xan.tho.li′ti.cus. Gr. adj. *xanthos* yellow; N.L. masc. adj. *lyticus* (from Gr. masc. adj. *lutikos*), able to loosen, able to dissolve; N.L. masc. adj. *xantholiticus* (*sic*) yellow and soluble (referring to the yellow color of the vegetative mycelium and the tendency of the organism to lyse when maintained on some solid media).

Spore chains in Section *Spirales*. Sporulating aerial mycelium is poorly developed on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Two observers report compact spirals on salts-starch agar; one observer reports spirals on yeast-malt agar and glycerol-asparagine agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray color series when adequate sporulating aerial mycelium is formed on salts-starch agar or glycerol-asparagine agar. Color of aerial mycelium cannot be determined on yeast-malt agar or oatmeal agar. Reverse side of colony is pale yellow green to greenish yellow on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; moderate yellow to light olive brown on yeast-malt agar.

Color in medium: melanoid pigments are not formed in peptone-yeast-iron agar, tyrosine agar, or tryptone-yeast broth. Yellow pigment is found in the medium in glycerol-asparagine agar and sometimes in oatmeal agar or salts-starch agar. This pigment is not pH-sensitive when tested with 0.05 M NaOH or HCl.

D-Glucose, D-xylose, and D-fructose are utilized for growth. Utilization of iso-inositol is doubtful; no growth or only traces of growth with L-arabinose, D-mannitol, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. peucetius*, AB045887, 100%; *S. kurssanovii*, AB184325, 99.9%; *S. graminofaciens*, AJ781329, 99.8%.

Type strain: ATCC 27481, CBS 655.72, BCRC 12646, DSM 40244, NBRC 13354, JCM 4282, JCM 4863, NCIMB 9857, NRRL B-12153, NRRL-ISP 5244, RIA 1315, VKM Ac-1872.

Sequence accession no. (16S rRNA gene): AB184349.

524. **Streptomyces xanthophaeus** Lindenbein 1952, 378[AL]

xan.tho.pha′e.us. N.L. masc. adj. *xanthophaeus* (from Gr. adj. *xanthopos* golden-looking) shining like gold.

Spore chains in Section *Rectiflexibiles*. Mature spore chains are very long, usually more than 50 spores per chain. This morphology is found on oatmeal agar, salts-starch agar, and glycerol-asparagine agar; poor sporulation on yeast-malt agar. Spore surface is smooth.

Color of colony: aerial mass color in the Red or Gray color series on oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Nearest matching color tabs: grayish yellowish pink (5dc, Red series) to light grayish reddish brown (5fe to 4li, Gray color series). Reverse side of colony is colorless or characteristic grayed yellow to yellow-brown on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar, but very dark reddish gray to near black on salts-starch agar. Reverse color is not a pH indicator.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast extract broth. Pigments other than traces of yellow are not formed in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. D-Glucose is utilized for growth. No growth or only trace of growth on L-arabinose, sucrose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose.

Type strain shows the highest sequence similarity to: *S. nojiriensis*, AJ781355, 100%; *S. sporoarveus*, AJ781370, 100%; *S. vinaceus*, AB184394, 99.8%; *S. cirratus*, AY999794, 99.8%; *S. goshikiensis*, EF178693, 99.8%; *S. colombiensis*, DQ026646, 99.7%; *S. cinnamonensis*, AB184707, 99.7%; *S. avidinii*, AB184395, 99.7%; *S. sporoverrucosus*, DQ442544, 99.7%; *S. subrutilus*, X80825, 99.6%; *S. virginiae*, D85119, 99.5%.

Sequence accession no. (16S rRNA gene): DQ442560.

525. **Streptomyces yanglinensis** Xu, Wang, Cui, Huang, Liu, Zheng and Goodfellow 2006, 1114[VP]

yang.lin.en′sis. N.L. masc. adj. *yanglinensis* of or belonging to Yanglin, the source of the soil from which the type strain was isolated.

Neutrotolerant, acidophilic streptomycete that forms branched substrate and aerial hyphae. Smooth-surfaced spores are borne on flexuous spore chains. Gray-colored colonies that carry an abundant white to gray aerial spore mass are formed on acidified oatmeal agar; blackish colonies bearing an abundant white to gray aerial spore mass are formed on ISP 9 agar supplemented with fructose, mannose, or sucrose (each at 1%, w/v). Diffusible pigments are not produced, and melanin pigments are not formed on peptone-yeast extract-iron agar or tyrosine agar. Degrades starch and Tween 80, but not adenine, guanine, or xanthine. Adonitol, cellobiose, D-galactose, D-glucose, D-inulin, D-lactose, D-mannitol, D-salicin, and D-sorbitol (each at 1%, w/v) are used as sole carbon sources for energy and growth, but melezitose (at 1%, w/v), adipic acid, L-alanine, DL-aminobutyric acid, L-arginine, α-L-aspartic acid, L-cysteine, L-phenylalanine, L-valine, sodium acetate, sodium citrate, and sodium oxalate (each at 0.1%, w/v) are not. L-Glutamic acid is used as a sole carbon and nitrogen source, but L-alanine, L-arginine, L-aspartic acid, L-isoleucine, and L-phenylalanine (each at 0.1%, w/v) are not. Growth occurs at temperatures between 20 and 37°C, but not at 15°C, and at pH values between 4.5 and 7.0, but not at pH 3.5. Does not grow in the presence of 5% (w/v) NaCl. Sensitive to filter-paper discs soaked in the following (µg/ml unless indicated): cephalothin (30), doxycycline hydrochloride (30), erythromycin (15), josamycin (15), kanamycin sulfate (30), minocycline hydrochloride (30), neomycin sulfate (30), sulfamethoxazole (25), and tobramycin sulfate (10), but not to filter-paper discs soaked in acetylspiramycin (15), amoxycillin (10), ampicillin (10), azithromycin (30); azetreonam (30), carbenicillin (10), ciprofloxacin (5), ofloxacin (5), penicillin G (10 IU/ml), rifampin, streptomycin sulfate (10), or tetracycline hydrochloride (30).

Type strain shows no sequence similarity over 99%. Type strain shows DNA–DNA similarity to: *S. yeochonensis* NRRL B-24245^{T}, 21.0%; *S. guanduensis* JCM 13274^{T}, 23.1%; *S. paucisporeus* JCM 13276^{T}, 25.9%; *S. rubidus* JCM 13277^{T}, 23.8%.

Source: the type strain was isolated from a pine-forest soil in Yanglin, Yunnan Province, People's Republic of China.

DNA G+C content (mol%): 74.8.

Type strain: 1307, CGMCC 4.2023, JCM 13275.

Sequence accession no. (16S rRNA gene): AY876940.

526. **Streptomyces yanii** (Yan, Jiang and Zhang 1987) Liu, Shi, Zhang, Zhou, Lu, Li, Huang, Rodríguez and Goodfellow 2005b, 1609^{AL} ("*Microstreptospora cinerea*" Yan, Jiang and Zhang 1987)

ya'ni.i. N.L. gen. masc. n. *yanii* of Yan, named in honor of Yunchu Yan, a Chinese microbiologist.

Forms an extensively branched substrate mycelium and aerial hyphae. The substrate mycelium carries abundant spherical, smooth-surfaced spores (about 2.5 µm in diameter) singly or in short chains of 2–4 spores on short sporophores. Short chains of ellipsoidal smooth-surfaced spores (0.8 × 2.0 µm in diameter) are formed on aerial hyphae. The latter are usually formed only on inorganic media; an abundant gray aerial spore mass is apparent on oatmeal and Krass's No. 1 agars. Forms an abundant gray to black substrate mycelium on Czapek's, Krass's, and oatmeal agars. Gelatin and starch are degraded, but not cellulose or tyrosine. Nitrate is reduced. H_2S is not formed. Milk is coagulated but not peptonized. Good growth occurs at 18–35°C and pH 6–9. Whole-organism hydrolysates contain major proportions of LL-A_2pm, glycine, galactose, and mannose, and a trace of ribose. The muramic acid of the peptidoglycan is *N*-acetylated. The predominant isoprenologs are tetra- and hexa-hydrogenated menaquinones with nine isoprene units and the major phospholipids are diphosphatidylglycerol and phosphatidylinositol mannosides.

Type strain shows the highest sequence similarity to: *S. atratus*, DQ026638, 99.8%; *S. sanglieri*, AB249945, 99.7%; *S. cinereorectus*, AB184646, 99.5%; *S. pulveraceus*, AB184806, 99.5%; *S. griseinus*, AB184205, 99.4%; *S. pluricolorescens*, DQ442540, 99.4%; *S. alboviridis*, AB184256, 99.4%; *S. mediolani*, AB184674, 99.4%; *S. griseoplanus*, AY999894, 99.4%; *S. sindenensis*, AB184759, 99.4%; *S. rubiginosohelvolus*, AB184240, 99.4%; *S. gelaticus*, DQ026636, 99.4%; *S. fimicarius*, AY999784, 99.4%; *S. globisporus* subsp. *globisporus*, EF178686, 99.4%; *S. fulvorobeus*, AB184711, 99.4%; *S. lipmanii*, AB184148, 99.4%; *S. badius*, AY999783, 99.4%; *S. microflavus*, DQ445795, 99.4%; *S. argenteolus*, AB045872, 99.4%; *S. griseolus*, AB184768, 99.4%; *S. acrimycini*, AY999889, 99.4%; *S. lavendulae* subsp. *lavendulae*, AB184080, 99.4%; *S. flavofuscus*, AB249935, 99.4%; *S. anulatus*, DQ026637, 99.4%; *S. griseus* subsp. *griseus*, AY207604, 99.4%; *S. cavourensis* subsp. *washingtonensis*, DQ026671, 99.4%; *S. praecox*, AB184293, 99.4%; *S. cyaneofuscatus*, AB184860, 99.4%; *S. albovinaceus*, AB249958, 99.3%; *S. flavovirens*, DQ026635, 99.3%; *S. parvus*, DQ442537, 99.3%; *S. halstedii*, EF178695, 99.3%; *S. baarnensis*, EF178688, 99.3%; *S. luridiscabiei*, AF361784, 99.2%; *S. californicus*, AB184755, 99.2%; *S. floridae*, AB184656, 99.2%; *S. flavogriseus*, AJ494864, 99.2%; *S. nitrosporeus*, EF178680, 99%; *S. bacillaris*, AB184439, 99%. Source: the sole strain was isolated from a mud sample collected from a sewage ditch in Zhanjiang City, Guangdong Province, China.

DNA G+C content (mol%): 69.4.

Type strain: 80-133, AS 4.1146, NBRC 14669, JCM 3331.

Sequence accession no. (16S rRNA gene): AB006159.

Further comments: Streptomyces yanii Liu et al. 2005b was previously known as "*Microstreptospora cinerea*" Yan et al. 1987.

527. **Streptomyces yatensis** Saintpierre, Amir, Pineau, Sembiring and Goodfellow 2003b, 1219^{VP} (Effective publication: Saintpierre, Amir, Pineau, Sembiring and Goodfellow 2003a, 25.)

ya.ten'sis. N.L. masc. adj. *yatensis* pertaining to the Yaté region of New Caledonia, the source of the isolate.

Forms an extensively branched substrate mycelium which carries aerial hyphae that differentiate into spiral spore chains with three or four turns; there are 15–20 cylindrical to barrel-shaped spores per chain. Spore surface is rugose. On oatmeal agar, the spore mass is initially gray, then black; the substrate mycelium is grayish-yellow. Mela-

nin pigments are not produced. Growth occurs at 20, 30, and 37°C, but not at 10°C or 45°C. It also occurs in the presence of ampicillin (10 µg/ml), lysozyme, penicillin (10), and sodium chloride (3%, w/v) but not in the presence of carbenicillin (100), chloramphenicol (30), gentamicin sulfate (10), neomycin sulfate (30), streptomycin sulfate (30), tetracycline hydrochloride (30), or sodium chloride (5% w/v). The organism shows activity against some of the microbial strains isolated from clinical material (the *Bacillus*, *Corynebacterium*, *Candida albicans*, *Klebsiella pneumoniae*, and *Staphylococcus aureus* strains) and against the phytopathogen (*Fusarium oxysporum*) but not against strains of *Erwinia*, *Escherichia coli*, *Pseudomonas aeruginosa*, or *Staphylococcus epidermidis*. 70% toxicity is shown against Kb cells using a concentration of 10 µg/ml of a crude extract.

Type strain shows no sequence similarity over 99%.

Source: the organism was isolated from a ferraltic soil collected at the southern end of New Caledonia.

DNA G+C content (mol%): not known.

Type strain: SFOCin 76, DSM 41771, JCM 13244, NBRC 101000, NRRL B-24116.

Sequence accession no. (16S rRNA gene): AB249962.

528. **Streptomyces yeochonensis** Kim, Seon, Jeon, Bae and Goodfellow 2004, 213^{VP}

ye.o.chon.en′sis. N.L. masc. adj. *yeochonensis* of or belonging to Yeochon, a province in Korea, referring to the place where the organism was first isolated.

Aerobic, Gram-stain-positive, nonmotile, neutrotolerant acidophilic streptomycete that forms extensively branched substrate and aerial mycelia. Smooth-surfaced spores are borne in flexuous spore-chains. Aerial spore mass color is gray. Substrate mycelia have no distinctive color; diffusible pigments are not produced. pH range for growth is 4.3–7.3. Casein, gelatin, guanine, starch, and Tween 80 are degraded, but elastin, hypoxanthine, testosterone, Tween 20, tyrosine, and xanthine are not. Good growth occurs between 25 and 37°C, but not at 12 or 45°C. The sugars erythritol, inulin, melezitose, salicin, ribitol, and sorbitol (all at 1%, w/v) are used as sole carbon sources, as are β-hydroxybutyric acid, D-gluconic acid, hippuric acid, α-ketoglutaric acid, 2-keto-D-glucuronic acid, lactic acid, malic acid, malonic acid, oxalic acid, pyruvic acid, and succinic acid (as sodium salts) (all at 0.1%, w/v).

Type strain shows no sequence similarity over 99%.

Source: the type strain was isolated from acidic soil collected in the Yeochon area of the Republic of Korea.

DNA G+C content (mol%): not known.

Type strain: CN732, JCM 12366, KCTC 9926, IMSNU 50114, NBRC 100782, NRRL B-24245.

Sequence accession no. (16S rRNA gene): AF101415.

529. **Streptomyces yerevanensis** (Tsyganov, Zhukova and Timofeeva 1964) Goodfellow, Williams and Alderson 1986a, 575^{VP} (Effective publication: Goodfellow, Williams and Alderson 1986a, 52.) ["*Macrospora violaceus*" (*sic*) Tsyganov, Zhukova and Timofeeva 1964, 868; *Microellobosporia violacea* Pridham *in* Buchanan and Gibbons 1974, 844]

ye.re.van.en′sis. N.L. masc. adj. *yerevanensis* of or pertaining to Yerevan, Armenia.

Forms extensively branched substrate and aerial mycelium. Short chains (2–8) of smooth-surfaced spores borne on both the substrate and aerial mycelium. Aerial spore mass is light mouse gray; reverse color is violet and the pigment is pH-sensitive. Violet diffusible pigment, which is also pH-sensitive, is produced. Does not form melanin pigments. Adenine, esculin, arbutin, casein, hypoxanthine, starch, testosterone, and tyrosine are degraded but allantoin, chitin, guanine, lecithin, pectin, urea, xanthine, and xylan are not. Adonitol, L-arabinose, cellobiose, D-fructose, D-glucose, *myo*-inositol, inulin, D-lactose, mannitol, D-mannose, melibiose, melezitose, raffinose, L-rhamnose, salicin, sucrose, and D-xylose are used as sole carbon sources but D-galactose, maltose, trehalose, and xylitol are not. Grows on L-arginine, L-histidine, potassium nitrate, L-serine, L-threonine, and L-valine, but not on DL-α-amino-n-butyric acid, L-cysteine, L-hydroxyproline, L-methionine, or L-phenylalanine, as sole nitrogen source. Growth occurs at 10 and 37°C, but not at 4 or 45°C. Tolerant to phenol (0.1%, w/v) and sodium chloride (4%, w/v), but not to sodium azide (0.01%, w/v). Resistant to rifampin but sensitive to sodium chloride (7%, w/v). Does not show antimicrobial activity against *Aspergillus niger* LIV 131, *Bacillus subtilis* NCIB 3610, *Candida albicans* CBS 562, *Escherichia coli* NCIB 9132, *Micrococcus luteus* NCIB 196, *Pseudomonas fluorescens* NCIB 9046^T, *Saccharomyces cerevisiae* CBS 1171^T, or *Streptomyces murinus* ISP 5091. The peptidoglycan contains LL-A_2pm as the major diamino acid. The organism has a type II phospholipid pattern (Lechevalier et al., 1977) and contains major amounts of tetra-, hexa-, and octahydrogenated menaquinones with nine isoprene units (Alderson et al., 1985; Collins et al., 1984). Produces violacin, a pigmented antibiotic of the rhodomycin-cinerubin-mycetin type.

Type strain shows the highest sequence similarity to: *S. litmocidini*, AB184149, 99.8%; *S. exfoliatus*, AB184324, 99.4%; *S. venezuelae*, AB045890, 99.4%; *S. zaomyceticus*, EF178685, 99.4%; *S. lateritius*, AB184324, 99.3%; *S. wedmorensis*, DQ442557, 99.3%; *S. omiyaensis*, EF178697, 99.3%.

Source: isolated from soil, Armenia, USSR.

DNA G+C content (mol%): 68.0–70.0.

Type strain: AS 4.1464, ATCC 43727, BCRC 11564, DSM 43167, IFM 1151, IFM 1242, NBRC 12517, IMET 43616, JCM 3047, JCM 3065, KCC A-0047, LMG 19363, NCIB (now NCIMB) 9589, NRRL B-16943, RIA 795, VKM Ac-1234.

Sequence accession no. (16S rRNA gene): EF178684.

Further comments: for the transfer of *Microellobosporia violacea* (Tsyganov et al. 1964) Pridham 1974 to the genus *Streptomyces* Waksman and Henrici 1943 it is necessary to substitute a new specific epithet to produce *Streptomyces yerevanensis* because there is a senior homonym, *Streptomyces violaceus* (Rossi Doria 1891) Waksman 1953, included on the Approved Lists of Bacterial Names [Rules 34a and 41a of the *Bacteriological Code* (1990 Revision)].

530. **Streptomyces yogyakartensis** Sembiring, Ward and Goodfellow 2001, 1619^{VP} (Effective publication: Sembiring, Ward and Goodfellow 2000, 363.)

yog.ya.kar.ten′sis. N.L. masc. adj. *yogyakartensis* of or pertaining to Yogyakarta, Indonesia.

Spore chains are *Spirales*; spore surface is rugose. On oatmeal agar the spore mass is gray, the substrate mycelium is grayish-yellow, and the diffusible pigment is yellow. Melanin pigments are not produced. The organism grows at 45°C, degrades adenine but does not reduce nitrate.

Type strain shows the highest sequence similarity to: *S. violaceusniger*, AJ391823, 100%; *S. albiflaviniger*, AJ391812, 99.7%; *S. endus*, AY999911, 99.5%; *S. sporocinereus*, AB249933, 99.5%; *S. demainii*, DQ334782, 99.5%; *S. hygroscopius* subsp. *hygroscopius*, AB184428, 99.5%; *S. javensis*, AJ391833, 99.2%. Source: isolated from non-rhizosphere soil adjacent to a stand of the tropical legume, *Paraserianthes falcataria*.

DNA G+C content (mol%): not known.

Type strain: C4R3, DSM 41766, JCM 11448, NBRC 100779, NCIMB 13681.

Sequence accession no. (16S rRNA gene): AB249942.

531. **Streptomyces yokosukanensis** Nakamura 1961, 94[AL]

yo.ko.su'ka.nen'sis. N.L. masc. adj. *yokosukanensis* (*sic*) of or belonging to Yokosuka City, Kanagawa Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore chains in Section *Spirales* or *Retinaculiaperti*. Tight spirals are common at the ends of long spore chains. Open spirals, hooks, and flexuous chains are also found. Spore surface is spiny according to one observer; another observer finds only smooth spores.

Color of colony: aerial mass color in the Red color series (grayish yellowish pink) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. Reverse side of colony with no distinctive pigments (grayish yellow, light yellowish brown, olive-brown, or strong brown) on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth. No pigment or only a trace of yellow is found in medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, D-xylose, iso-inositol, D-mannitol, D-fructose, rhamnose, and raffinose are utilized for growth. No growth or only trace of growth with sucrose.

Type strain shows the highest sequence similarity to: *S. cellostaticus*, AB184192, 99.5%; *S griseochromogenes*, AB184387, 99.3%.

Source: isolated from soil from Yokosuka City, Kanagawa Prefecture, Japan.

DNA G+C content (mol%): not known.

Type strain: ATCC 25520, CBS 662.69, BCRC 11875, DSM 40224, NBRC 13108, JCM 4137, JCM 4559, NRRL B-3353, NRRL-ISP 5224, RIA 1300, VKM Ac-1713.

Sequence accession no. (16S rRNA gene): DQ026652.

532. **Streptomyces yunnanensis** Zhang, Li, Cui, Li, Xu and Jiang 2003, 220[VP]

yun.nan.en'sis. N.L. masc. adj. *yunnanensis* of or pertaining to Yunnan, a province of south-west China.

Spore chains with many spores are spiral. The spores are rugose with short spines and are short pillar-shaped (0.5–1.0 μm in diameter) and nonmotile. Vegetative and aerial hyphae are abundant and well-developed. Diffusible pigments are not produced and melanin is not produced. Milk is not coagulated but peptonized, starch is hydrolyzed, and H_2S is not produced. Nitrate is not reduced and gelatin is liquefied. Does not hydrolyze cellulose. Utilizes glucose, fructose, rhamnose, inositol, mannitol, arabinose, and raffinose for growth; does not utilize sucrose or xylose. It has antimicrobial activity against *Aspergillus niger* but not against *Bacillus subtilis*. Optimum growth is at 28°C. The cell wall contains LL-A_2pm and glycine (cell-wall chemotype I). Whole-cell hydrolysates contain galactose.

Type strain shows the highest sequence similarity to: *S. albulus*, AB024440, 99.7%; *S. noursei*, AB184678, 99.7%.

Source: the type strain was isolated from red soil of suburb of Kunming in Yunnan, China.

DNA G+C content (mol%): not known.

Type strain: YIM 41004, CGMCC 4.1004, DSM 41793, JCM 12115, NBRC 100781.

Sequence accession no. (16S rRNA gene): AF346818.

533. **Streptomyces zaomyceticus** Hinuma 1954, 134[AL]

za.o.my.ce'ti.cus. English n. N.L. n. *zaomycinum* zaomycin, an antibiotic named after the Mount Zao, Japan, the source of the soil from which the organism was isolated; N.L. masc. suff. *-icus* suffix used with the sense of belonging to; N.L. masc. adj. *zaomyceticus* belonging to zaomycin.

Spore chains in Section *Rectiflexibiles*. Mature spore chains generally are long, often with more than 50 spores per chain. Long chains are flexuous, but true spirals are not formed. This morphology is seen on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar but not on salts-starch agar. Spore surface is smooth.

Color of colony: aerial mass color in the Gray or White color series on yeast-malt agar, oatmeal agar, and glycerol-asparagine agar. A good aerial mycelium is not produced on salts-starch agar. Nearest matching color tabs in the Gray color series are 2dc, yellowish gray, and d, light gray. Reverse side of colony with no distinctive pigments (olive brown to yellowish brown on yeast-malt agar; light grayish yellow to olive brown on oatmeal agar and salts-starch agar; grayish yellow on glycerol-asparagine agar).

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar, tyrosine agar, and tryptone-yeast broth, but the reaction is weak in tyrosine agar. No pigment other than a melanoid pigment is found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar.

D-Glucose, L-arabinose, and D-xylose are utilized for growth. No growth or only traces of growth with iso-inositol, D-mannitol, D-fructose, rhamnose, sucrose, and raffinose.

Type strain shows the highest sequence similarity to: *S. exfoliatus*, AB184324, 99.9%; *S. venezuelae*, AB045890, 99.9%; *S. wedmorensis*, DQ442557, 99.7%; *S. lateritius*, AB184324, 99.7%; *S. omiyaensis*, EF178697, 99.6%; *S. litmocidini*, AB184149, 99.6%; *S. yereyanensis* EF178684, 99.4%; *S. narbonensis*, DQ445794, 99.3%.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 27482, CBS 649.72, BCRC 12317, DSM 40196, NBRC 13348, JCM 4179, JCM 4864, NCIMB 9850, NRRL B-2038, NRRL-ISP 5196, RIA 1309, VKM Ac-1192.

Sequence accession no. (16S rRNA gene): EF178685.

Genus *incertae sedis* I. **Kitasatospora** corrig. Ōmura, Takahashi, Iwai and Tanaka 1983, 672^VP (Effective publication: Ōmura Takahashi, Iwai and Tanaka 1982, 1014.) emend. Zhang, Wang and Ruan 1997, 1053

Peter Kämpfer

Ki.ta.sa.to.spo′ra. N.L. fem. n. *Kitasatoa* named for Shibasaburo Kitasato (1852–1931), a Japanese bacteriologist; N.L. fem. n. *spora* a seed and, in biology, a spore; N.L. fem. n. *Kitasatospora* Kitasato spore.

Aerobic. Gram-stain-positive, non-acid–alcohol-fast actinomycetes which form an intensively branched, non-fragmenting mycelium. A stable substrate mycelium is as well-developed as that of streptomycetes, and the aerial mycelium bears long spore chains of more than 20 spores. Does not form sporangia. The major constituents of the cell wall are glycine, galactose, and *meso*-A_2pm or LL-A_2pm, depending on the type of cells analyzed. When cells are grown on agar media, aerial spores contain LL-A_2pm, whereas the substrate mycelium contains *meso*-A_2pm. When cells are grown in liquid media, submerged spores which contain LL-A_2pm are formed while the filamentous mycelia contain *meso*-A_2pm. Whole-cell hydrolysates contain galactose, but lack arabinose, madurose, and xylose. Hexa- and octa-hydrogenated menaquinones with nine isoprene units are the predominant isoprenologs, cells are rich in saturated, iso- and anteiso-fatty acids, and have complex polar lipid patterns which contain diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol and phosphatidylinositol mannosides. The glycolate test is negative. The organism is chemo-organotrophic, and grows from 15 to 42°C, and within the pH range 5.5 to 9.0.

Source: not known.

DNA G+C content (mol%): 66–77.

Type species: **Kitasatospora setae** corrig. Ōmura, Takahashi, Iwai and Tanaka 1983, 672 (Effective publication: Ōmura, Takahashi, Iwai and Tanaka 1982, 1014).

Further descriptive information

The genus *Kitasatosporia* (*sic*) was proposed by Ōmura et al. (1982) for actinomycetes that were phenotypically very similar to members of the genus *Streptomyces*, but which contained major amounts of the *meso*-isomer of A_2pm and galactose in their cell walls. Zhang et al. (1997), who revived the genus, corrected the name to *Kitasatospora* albeit without a formal proposal. Some confusion has arisen as to whether the genus name *Kitasatospora* is illegitimate, because no formal proposal was made for the transfer of *Streptomyces setae* to *Kitasatospora setae*. This also has the effect of automatically changing the spelling of all species names validly published under *Kitasatosporia* (*sic*). The problem was handled by the Judicial Commission of the ICSP (De Vos et al., 2005), with the result that no further action is required by the Judicial Commission as all names listed under the genus *Kitasatospora* were validly published in accordance with the Rules of the *Bacteriological Code* (1990 Revision).

The distribution of the two isomers of A_2pm in cells of *Kitasatospora* grown at different stages of differentiation was studied by Takahashi et al. (1983), who found that *Kitasatospora* species contained LL-A_2pm in the aerial mycelium and *meso*-A_2pm in the vegetative mycelium, while *Streptomyces* species contained only LL-A_2pm in both aerial and vegetative mycelia. The relative amounts of the two isomers varied in different experiments, and some *Streptomyces* species were also found to contain various amounts of *meso*-A_2pm, though *Kitasatospora* species consistently had a much higher ratio of *meso*-A_2pm to LL-A_2pm than *Streptomyces* species (Wellington et al., 1992). Strains assigned to the genus *Kitasatospora* were, unlike most *Streptomyces* species, resistant to polyvalent *Streptomyces* phages (Wellington et al., 1992) and formed submerged spores in liquid culture (Ōmura et al., 1982; Takahashi et al., 1983). Wellington et al. (1992) also found that the 16S rRNA gene sequence of *Kitasatospora setae* showed 91.6% similarity to the 16S rRNA gene sequence of *Streptomyces baldaccii*, and that a *Streptomyces*-specific oligonucleotide probe could recognize members of all four valid *Kitasatospora* species. These observations, and the fact that many phenotypic properties are shared by *Kitasatospora* and *Streptomyces* species, led Wellington and her colleagues to propose that all *Kitasatospora* species should be reclassified as *Streptomyces* species. These findings were supported by Ochi and Hiranuma (1994) on the basis of results from an analysis of the N-terminal sequences of ribosomal protein AT-L30.

In contrast, Nakagaito et al. (1992a) had assigned *Kitasatospora* and the *Streptomyces* species to distinct clusters based on DNA–DNA reassociation and phenetic studies. In addition, Kim et al. (1996) conducted a 16S rRNA gene sequence-based analysis of members of many *Streptomyces* species and found that the three *Kitasatospora* species formed a distant lineage in the "*Streptomyces*" tree. Zhang et al. (1997) determined the nucleotide sequences of 16S rRNA genes and the 16S–23S rRNA gene spacers of 12 actinomycete strains which were either previously classified as *Kitasatospora* strains or defined as *Streptomyces* strains, but had been found to contain major amounts of *meso*-A_2pm in their whole-cell hydrolysates. On the basis of their results, Zhang and his colleagues revived the genus *Kitasatospora* Ōmura et al. (1982).

The genus *Kitasatospora* can be distinguished from the genus *Streptomyces* by the ratio of *meso*-A_2pm to LL-A_2pm in whole-cell hydrolysates. The *meso*-A_2pm content is 49–89% in *Kitasatospora* strains and 1–16% in *Streptomyces* strains. Galactose is present in whole-cell hydrolysates of *Kitasatospora* strains, but not in those of *Streptomyces* strains. At the time of writing, the genus encompassed twelve species with validly published names. Representatives of each of these species with validly published names form a distinct line in the 16S rRNA *Streptomycetaceae* gene tree (Figure 339). On the basis of 16S rRNA gene sequence data, all the species are grouped together, showing high similarities. They are very similar to members of the genera *Streptomyces* and *Streptacidiphilus*, i.e. they produce aerial mycelia with long chains of spores, contain hexa- and octa-hydrogenated menaquinones with nine isoprene units as predominant isoprenologs, are rich in saturated, iso- and anteiso-fatty acids, and have complex polar lipid patterns which contain major amounts of

diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, and phosphatidylinositol mannosides. However, *Kitasatospora* and *Streptomyces* are clearly sister taxa as they share so many phenotypic properties.

Enrichment and isolation procedures

Enrichment and isolation procedures are as described for *Streptomyces* species.

Maintenance procedures

Maintenance procedures are as for *Streptomyces* species.

Differentiation of the genus *Kitasatospora* from other genera

Despite some differences, members of the family *Streptomycetaceae* are morphologically and chemically homogeneous (Table 263). Identification of most species is difficult, because in many instances only one (the type) or a few strains have been examined. *Kitasatospora* species may be distinguished from other genera in the family by slight differences in cell-wall sugars and the presence of *meso*-A_2pm in the peptidoglycan (Table 263). Table 273 lists some characters which can be used to distinguish between *Kitasatospora* species.

[a]+, Positive; −, negative; (+), weakly positive; ±, doubtful; nd, not determined.

[b]For the following properties, tests in which strain DSM 41680^{T} was not included are indicated by an asterisk. Spores of all of the tested strains are cylindrical with smooth surface. All strains were positive for the production of H_2S*, growth on (+)-D-glucose, and produced acid phosphatase, alkaline phosphatase, esterase (C4), esterase lipase (C8), and leucine arylamidase (API ZYM tests). Good growth occurred at temperatures of 15–32°C and pH 5.0–7.0. All strains were sensitive to chloramphenicol (30 μg)*, ciprofloxacin (5 μg)*, imipenem (10 μg)*, kanamycin sulfate (30 μg)*, nalidixic acid (50 μg/ml agar)*, oxytetracycline (30 μg)*, rifampin (30 μg)*, streptomycin sulfate (10 μg)*, and vancomycin (30 μg)*. They did not use cellulose* as a sole carbon source; did not produce α-chymotrypsin, cystine arylamidase, α-galactosidase, β-glucuronidase, α-fucosidase, lipase (C14), trypsin, or valine arylamidase (API ZYM tests); and did not grow in the presence of NaCl (4%, w/v), at 42°C, or at pH 4.0 or pH 10.

[d]Data from Kusakabe and Isono (1988).

[e]Data from Takahashi et al. (1984).

List of species of the genus *Kitasatospora*

1. **Kitasatospora setae** corrig. Ōmura, Takahashi, Iwai and Tanaka 1983, 673^{VP} (Effective publication: Ōmura, Takahashi, Iwai and Tanaka 1982, 1014.)

se′ta.e. N.L. gen. n. *setae* of Seta, Japan, where the bacterium was isolated.

Spore chain morphology *Rectiflexibiles* type with a smooth spore surface. Color of vegetative mycelia is pale yellow to light ivory on yeast extract-malt extract and glycerol-asparagine agars (Shirling and Gottlieb, 1966). Aerial mass color is white or light gray on yeast extract-malt extract and inorganic salts-starch agars. Forms yellow diffusible pigment on inorganic salts-starch agar. Nitrate is not reduced, milk is coagulated. Raffinose, D-fructose, L-rhamnose, sucrose, melibiose, D-mannitol, iso-inositol, and cellulose are not utilized; D-glucose, L-arabinose, and D-xylose are used as sole carbon sources. Can grow in NaCl at a concentration up to 1.5%. The temperature range for growth is 15–37°C. Cell wall contains both *meso*- and LL-A_2pm. Whole-cell hydrolysates contain galactose, but lack arabinose, madurose, and xylose. Produces setamycin, an antibiotic active against trichomonads and bacteria.

The type strain shows its highest sequence similarities to the following *Kitasatospora* species: *Kitasatospora niigatensis*, AB022876, 99.1%; *Kitasatospora cineracea*, AB022875, 99.1%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: soil.

DNA G+C content (mol%): 73.1.

Type strain: KM-6054, ATCC 33774, DSM 43861, NBRC 14216, JCM 3304, NRRL B-16185, VKM Ac-900.

Sequence accession no. (16S rRNA gene): M55220.

2. **Kitasatospora arboriphila** Groth, Rodríguez, Schüetze, Schmitz, Leistner and Goodfellow 2004, 2125^{VP}

ar.bo.ri.phi′la. L. n. *arbor* a tree; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. fem. adj. *arboriphila* tree loving.

Spore chains are long, straight to spiral with hooks and loops with 20 or more cylindrical, smooth-surfaced spores (1.1–1.7 × 1.3–2.4 μm) per chain. Submerged spores are formed sparsely in liquid culture. Produces a yellowish-brown to dark brown or olive substrate mycelium and a gray to dark gray aerial spore mass on glycerol-asparagine, inorganic salts-

starch, oatmeal, and yeast extract-malt extract agars. Soluble pigments are not formed, but melanoid pigments are produced on peptone-yeast extract-iron and tyrosine agars. Temperature range for growth is 15–40°C (optimum 28–32°C); growth does not occur at 10°C or above 40°C. pH range for good growth is pH 5.0–8.0; growth does not occur at either pH 4.5 or pH 9.0. The cell wall contains *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated. Whole-organism hydrolysates contain galactose, mannose, glucose, and ribose. The major polar lipids are phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. The predominant fatty acids are $C_{16:0}$ iso (25%), $C_{15:0}$ iso (17%), and $C_{15:0}$ anteiso (12%); mycolic acids are absent. The major menaquinones are MK-9(H_6) (49%) and MK-9(H_8) (28%).

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* or *Streptomyces* species.

Source: the type strain was isolated from a soil sample collected from the roots of the tree *Maytenus aquifolia* in Ribeirao Preto, Brazil.

DNA G+C content (mol%): not known.

Type strain: 2291-120, HKI 0189, DSM 44785, JCM 13002, NBRC 101834, NCIMB 13973.

Sequence accession no. (16S rRNA gene): AY442267.

3. **Kitasatospora azatica** corrig. (Nakagaito, Yokota and Hasegawa 1992b) Zhang, Wang and Ruan 1997, 1053^{VP} (*Streptomyces azaticus* Nakagaito, Yokota and Hasegawa 1992b, 118)

a.za′ti.ca. N.L. fem. adj. *azatica* referring to the product azaamino acid antitumor agent.

Mature spore chains on aerial mycelia are long and straight to wavy. Spores are cylindrical with a smooth surface. Melanoid pigment is not produced. Yellow soluble pigment is produced on inorganic salts-starch agar. The color of the vegetative mycelia is pale yellow. The color of the aerial mycelia is white to grayish white. Growth is good, but aerial formation is only slight on yeast extract-malt extract agar, oatmeal agar, glycerol-asparagine agar, and Bennett's agar. The temperature range for growth is 11–34°C. The concentration of NaCl at which growth occurs is less than 3%. Nitrate is reduced, starch is hydrolyzed, gelatin is not liquefied, and milk is peptonized but not coagulated.

D-Glucose, D-fructose, D-xylose, and L-arabinose are utilized, but D-mannitol, rhamnose, raffinose, iso-inositol, and sucrose are not or poorly utilized. The cell wall contains both LL- and *meso*-A_2pm and a trace amount of glycine. Galactose is detected as whole-cell sugar. The phospholipid pattern is type II. MK-9(H_6) and MK-9(H_8) are detected.

Type strain shows the highest sequence similarity to following *Kitasatospora* species: *Kitasatospora nipponensis*, AY442263, 99.1%. The type strain shows its highest sequence similarity to *Streptomyces purpeofuscus*, AJ781364, 99.2%, but does not show any sequence similarities over 99% to any *Streptacidiphilus* species.

Source: not known.

DNA G+C content (mol%): 70.5.

Type strain: ATCC 29755, DSM 41650, NBRC 13803, JCM 8798.

Sequence accession no. (16S rRNA gene): U93312.

4. **Kitasatospora cheerisanensis** Chung, Sung, Mo, Son, Nam, Chun and Bae 1999, 757^{VP}

che.e.ri.san.en′sis. N.L. fem. adj. *cheerisanensis* of or pertaining to Cheerisan, the name of a mountain in Korea where the species was originated.

Spore chains are *Rectiflexibiles*, with 20 or more rod-shaped smooth-surfaced spores (0.75–0.90 × 1.2–1.5 μm) per chain. Submerged spores are formed in liquid culture. Produces a greenish-yellow substrate mycelium and a whitish-gray aerial mycelium on yeast extract-malt extract agar, inorganic salts-starch agar, tyrosine agar, Bennett's agar, and starch agar. Vegetative mycelia fragment into bacillary structures. Soluble pigments, including melanin, are not produced. Colonies lacking aerial mycelium during early growth stage were pasty, circular, convex, and dull milky. The strain is positive for catalase activity and reduction of nitrate. Acids are produced from arabinose, cellobiose, galactose, glucose, maltose, trehalose, and xylose. Casein, chitin, chitosan, starch, esculin, gelatin, hippurate, and Tweens 40, 60 and 80 are decomposed, but cellulose, hypoxanthine, and tyrosine are not. Growth occurs in the presence of 1% NaCl, but not in 3% NaCl. Good growth occurs at pH 7–8 and the optimum temperature range is 25–30°C. Arabinose, azelate, cellobiose, cronate, fumarate, D-glucose, galactose, iso-butyrate, malonate, maltose, rhamnose, trehalose, and xylose are utilized for growth, but not adonitol, fructose, or glycerol. Mannitol, *myo*-inositol, melezitose, raffinose, sorbitol, suberate, succinate, and sucrose are not utilized. Whole-cell hydrolysates contain glucose and mannose, but lack galactose. Phosphatidylethanolamine, phosphatidylinositol, and diphosphatidylglycerol are contained in the polar lipid fraction. The predominant fatty acids are saturated iso- and anteiso-branched as well as straight-chain fatty acids. The major menaquinone type is MK-9(H_8). This strain is susceptible to ampicillin, chloramphenicol, kanamycin, nalidixic acid, oxytetracycline, rifampin, and streptomycin. The type strain, YC75^T, produces bafilomycin-C1-like anti-fungal compounds.

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* or *Streptomyces* species.

Source: isolated from Cheerisan, Korea.

DNA G+C content (mol%): 75.8.

Type strain: YC75, KCTC 2395.

Sequence accession no. (16S rRNA gene): AF050493.

5. **Kitasatospora cineracea** Tajima, Takahashi, Seino, Iwai and Ōmura 2001, 1770^{VP}

ci.ne.ra′ce.a. L. fem. adj. *cineracea* similar to ash, ash-gray, referring to the color of the aerial mycelium.

The spore chains are straight and flexuous, with 20 or more rod-shaped, smooth-surfaced spores (0.9–1.0 × 0.6 μm) per chain. Submerged spores are formed in liquid culture. Produces yellowish brown vegetative mycelium and oyster-white to silver-gray aerial mycelium on yeast extract-malt extract agar, inorganic salts-starch agar, glycerol-asparagine agar, and sucrose-nitrate agar. Soluble pigments, including melanin, are not produced. The strain is positive for peptonization of milk and hydrolysis of starch.

D-Glucose, L-arabinose, D-xylose, raffinose, melibiose, and D-rhamnose are utilized for growth, but D-mannitol, D-fructose, inositol, sucrose, and cellulose are not utilized. The cell wall contains both *meso*- and LL-A_2pm. Whole-cell hydrolysates contain galactose, mannose, and ribose but lack arabinose and xylose. Phosphatidylethanolamine and phosphatidylinositol are contained in the polar lipid fraction. MK-9(H_6) and MK-9(H_8) are predominant menaquinones. The *N*-acyl type is the acetyl type. The temperature range for growth is 15–37°C. The strain is resistant to novobiocin at 100 µg/ml.

The type strain shows its highest sequence similarities to the following *Kitasatospora* species: *Kitasatospora niigatensis*, AB022876, 100%; *Kitasatospora phosalacinea*, AB022869, 99.2%; *Kitasatospora setae*, AB022868, 99.1%; *Kitasatospora griseola*, AB022870, 99.1%. The type strain does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: not known.

DNA G+C content (mol%): 73.7.

Type strain: SK-3255, NBRC 16452, JCM 10915, NRRL B-24134.

Sequence accession no. (16S rRNA gene): AB022875.

6. **Kitasatospora cochleata** corrig. (Nakagaito, Yokota and Hasegawa 1992b) Zhang, Wang and Ruan 1997, 1053^VP^ (*Streptomyces cochleatus* Nakagaito, Yokota and Hasegawa 1992b, 116)

co.chle.a′ta. L. fem. adj. *cochleata* spiral, referring to the formation of spiral aerial mycelia.

Mature spore chains are long, forming hooks and spirals on glycerol-asparagine agar, tyrosine agar, oatmeal agar, glucose-asparagine agar, and water agar. Spores are cylindrical with a smooth surface. The color of vegetative mycelia is grayish brown. The color of aerial mycelia is gray. Melanoid pigments are produced in tyrosine agar. Brown soluble pigments are produced on yeast extract-malt extract agar. Nitrate is not reduced, starch is hydrolyzed, gelatin is not liquefied, and milk is peptonized but not coagulated. D-Glucose and L-arabinose are utilized, but D-fructose, D-mannitol, D-xylose, rhamnose, iso-inositol, and sucrose are poorly utilized or not utilized. The temperature range for growth is 13–38°C. The concentration of NaCl at which growth occurs is less than 3%. The cell wall contains both LL- and *meso*-A_2pm and a small amount of glycine. Galactose and a trace of madurose are detected as whole-cell sugars. The phospholipid pattern is type II. MK-9(H_6) and MK-9(H_8) are detected.

The type strain shows its highest sequence similarity to *Kitasatospora paracochleata*, U93328, 99.5%. The type strain does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: not known.

DNA G+C content (mol%): 72.4.

Type strain: M-5, ATCC 51235, DSM 41652, NBRC 14768, JCM 8799.

Sequence accession no. (16S rRNA gene): U93316.

7. **Kitasatospora cystarginea** corrig. Kusakabe and Isono 1992, 327^VP^ (Effective publication: Kusakabe and Isono 1988, 1758.)

cys.tar.gi′ne.a. N.L. n. *cystarginum* antibiotic cystargin; N.L. fem. adj. *cystarginea* referring to anti-fungal antibiotic cystargin that the organism produces.

Mature spore chains on aerial mycelium are long and spiral. The spores are cylindrical with a smooth surface. The color of vegetative mycelia is light brown. The color of aerial mycelia is gray. Neither melanoid pigment nor soluble pigment is produced. Nitrate is not reduced, starch is hydrolyzed and gelatin is not liquefied. Milk is peptonized but not coagulated. D-Glucose is utilized but D-fructose, D-xylose, L-arabinose, rhamnose, raffinose, sucrose, D-mannitol, and iso-inositol are not utilized or are poorly utilized. The temperature range for growth is 17–40°C. The cell wall contains LL- and *meso*-A_2pm and glycine. Galactose is detected as whole-cell sugar. The phospholipid pattern is type II. MK-9(H_6) and MK-9(H_8) are detected.

The type strain shows its highest sequence similarity to *Kitasatospora paracochleata*, U93328, 99%. The type strain does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: not known.

DNA G+C content (mol%): 70.6.

Type strain: RK-419, ATCC 49931, DSM 41680, FERM P-8006, NBRC 14836, JCM 7356, VKM Ac-2004.

Sequence accession no. (16S rRNA gene): U93318.

8. **Kitasatospora gansuensis** Groth, Rodríguez, Schüetze, Schmitz, Leistner and Goodfellow 2004, 2127^VP^

gan.su.en′sis. N.L. fem. adj. *gansuensis* of or pertaining to Gansu, a province in China, the origin of the soil from which the type strain was isolated.

Spore chains are long, straight to flexuous, with 20 or more cylindrical, smooth-surfaced spores (0.8–1.3 × 1.6–3.0 µm) per chain. Submerged spores and irregular fragments are formed in liquid culture. Produces a yellowish- or orange-brown to dark brown substrate mycelium and a white to beige aerial spore mass on glycerol-asparagine, inorganic salts-starch, oatmeal, and yeast extract-malt extract agars; soluble pigments are not formed on these media but melanoid pigments are produced on peptone-yeast extract-iron and tyrosine agars. Temperature range for growth is 6–32°C (optimum 25–28°C); growth does not occur below 6°C or at 35°C. pH range for good growth is pH 5.0–9.5; growth does not occur at pH 4.5 or above pH 9.5. The cell wall contains *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated and whole organism hydrolysates contain galactose, ribose, mannose, and rhamnose. The polar lipids are phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol, phosphatidylinositol mannosides, and an unknown glycolipid. The predominant fatty acids are $C_{15:0}$ anteiso (21%), $C_{16:0}$ (19%), $C_{15:0}$ iso (10%), and $C_{16:0}$ iso (10%); mycolic acids are absent. The major menaquinone is MK-9(H_6) (75%).

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* species, but shows its highest sequence similarities to the following *Streptomyces* species: *Streptomyces atroaurantiacus*, DQ026645, 99.4%; *Streptomyces indigoferus*, AB184214, 99%; *Streptomyces aburaviensis*, AY999779, 99%; *Streptomyces herbaricolor*, AB184801, 99%.

Source: the type strain was isolated from a sample of forest soil collected in the Lianhua Shan Reservation, Gansu Province, China.

DNA G+C content (mol%): not known.

Type strain: 2050-015, HKI 0314, DSM 44786, JCM 13003, NBRC 101835, NCIMB 13974.

Sequence accession no. (16S rRNA gene): AY442265.

9. **Kitasatospora griseola** corrig. Takahashi, Iwai and Ōmura 1985, 535[VP] (Effective publication: Takahashi, Iwai and Ōmura 1984, 384.)

gri.se.o′la. N.L. dim. fem. adj. *griseola* somewhat gray.

Spore chain morphology *Rectiflexibiles* type. The aerial spores are poorly septated and the spore surface is somewhat wrinkled. Color of vegetative mycelia is golden-olive to parchment on yeast extract-malt extract and glycerol-asparagine agars. Aerial mass color is gray or silvery-gray on most media. Forms a pinkish diffusible pigment on oatmeal (Shirling and Gottlieb, 1966) and glucose-asparagine agars. Can grow in NaCl at a concentration up to 2.0%. The temperature range for growth is 15–37°C; pH range for growth is pH 5.5–9.0. Cell wall contains both *meso*- and LL-A_2pm. Whole-cell hydrolysates contain galactose, but lack arabinose, madurose, and xylose. Produces setamycin, an antibiotic active against trichomonads and bacteria.

The type strain shows its highest sequence similarity to the following *Kitasatospora* species: *Kitasatospora paracochleata*, U93328, 99.2%; *Kitasatospora cineracea*, AB022875, 99.1%; *Kitasatospora niigatensis*, AB022876, 99%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: not known.

DNA G+C content (mol%): 66.0.

Type strain: AM-9660, DSM 43859, NBRC 14371, JCM 3339, NRRL B-16229, VKM Ac-2002.

Sequence accession no. (16S rRNA gene): U93320.

10. **Kitasatospora kifunensis** (Nakagaito, Shimazu, Yokota and Hasegawa 1992a) Groth, Schütze, Boettcher, Pullen, Rodriguez, Leistner and Goodfellow 2003, 2037[VP] (*Streptomyces kifunensis* Nakagaito, Shimazu, Yokota and Hasegawa 1992a, 630)

ki.fu.nen′sis. N.L. fem. adj. *kifunensis* of or belonging to Mount Kifune, Kyoto Prefecture, Japan, the source of the soil from which the organism was isolated.

Spore-chains are straight, hooked to spiral (*Rectiflexibiles* to *Spirales*). Spores are short, cylindrical and smooth-surfaced (1.2–1.3 × 0.6–0.7 μm). Submerged spores are formed sparsely in liquid culture. The color of vegetative mycelia is yellowish brown. The color of aerial mycelia is gray. Produces melanoid pigments on tyrosine agar, but not on peptone-yeast extract-iron agar or in tryptone-yeast extract broth. Nitrate is not reduced to nitrite. Gelatin is not liquefied and milk is not peptonized. Casein is degraded. H_2S is produced. Starch is hydrolyzed. Alkaline phosphatase, esterase (C4), esterase lipase (C8), β-galactosidase, α-glucosidase, leucine arylamidase, naphthol-AS-BI-phosphohydrolase, α-mannosidase (weak), and acid phosphatase are produced, but *N*-acetyl-β-glucosamidase, α-chymotrypsin, cystine arylamidase, α-fucosidase, α-galactosidase, β-glucosidase, β-glucuronidase, lipase (C14), trypsin, and valine arylamidase are not. L-Arabinose, D-galactose, D-glucose, glycerol, maltose, D-mannitol, D-mannose, sucrose, trehalose, and D-xylose are used as sole sources of carbon for energy and growth, but cellulose, chitin, D-fructose, iso-inositol, inulin, D-lactose, raffinose, L-rhamnose, and salicin are not. Temperature range for growth is 10–32°C; the organism does not grow below 10°C or above 32°C. pH range for growth is 5–9; growth does not occur at pH 4.5 or 9.5. Growth is inhibited by ampicillin (10 μg/ml, weak), chloramphenicol (30 μg/ml), ciprofloxacin (5 μg/ml), imipenem (10 μg/ml), kanamycin sulfate (30 μg/ml), methicillin (5 μg/ml), nalidixic acid (50 μg/ml), novobiocin (2.5 μg/ml), oxytetracycline hydrochloride (30 μg/ml), rifampin (30 μg/ml), streptomycin sulfate (10 μg/ml), sulfonamide (200 μg/ml, weak), and vancomycin hydrochloride (30 μg/ml), but not by lincomycin hydrochloride (2 μg/ml), norfloxacin (10 μg/ml), penicillin G (10 IU), or polymyxin B (3400 IU). The strain tolerates 2.5% but not 3.5% (w/v) NaCl. Resistance is shown to the polyvalent *Streptomyces* phage S7. Whole-cell chemistry reveals the presence of both *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated. Whole-organism hydrolysates contain galactose, mannose, glucose, and ribose and the major polar lipids are phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. Predominant fatty acids are $C_{16:0}$, $C_{15:0}$ anteiso, and $C_{15:0}$ iso; mycolic acids are absent. Major menaquinone is hexahydrogenated with nine isoprene units.

The type strain shows its highest sequence similarity to *Kitasatospora nipponensis*, AY442263, 99.1%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* species but shares its highest sequence similarities to the following *Streptomyces* species: *S. herbaricolor*, AB184801, 99.3%; *S. indigoferus*, AB184214, 99.3%; *S. aburaviensis*, AY999779, 99.3%; *S. chrysomallus* subsp. *fumigatus*, AB184645, 99.2%; *S. purpureus*, AJ781324, 99.2%; *S. xanthocidicus*, AY999858, 99.1%.

Source: the type strain was isolated from a soil sample obtained at Mount Kifune, Kyoto Prefecture, Japan.

DNA G+C content (mol%): 71.3.

Type strain: ATCC 51379, DSM 41654, NBRC 15206, JCM 9081.

Sequence accession no. (16S rRNA gene): AY442264.

11. **Kitasatospora mediocidica** corrig. Labeda 1988, 289[VP]

med.i.o.cid′i.ca. N.L. n. *mediocidinum* mediocidin, antbiotic produced by the type strain; L. fem. suff. *-ica* suffix used with the sense of pertaining to; N.L. fem. adj. *mediocidica* posessing mediocidin.

Sporulating aerial mycelium is not produced on any ISP media or on 15 additional media tested by cooperators. Single conidia were observed on the substrate mycelium on glucose-asparagine agar and Waksman's starch agar B. Masses of crystals are formed on the substrate growth on yeast-malt agar. The original description indicates that aerial mycelium was only poorly developed or absent on most media. Color of colony: no sporulation aerial mycelium was found on any of the media tried by the cooperators. Reverse side of colony is yellow to greenish yellow on yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar. This pigment is not pH-sensitive.

Color in medium: melanoid pigments are formed in peptone-yeast-iron agar and tryptone-yeast broth, but may not be formed in tyrosine agar. Trace of yellow pigment may be found in the medium in yeast-malt agar, oatmeal agar, salts-starch agar, and glycerol-asparagine agar; this pigment is not pH-sensitive.

D-Glucose, iso-inositol, and D-fructose are utilized for growth. No growth or only trace of growth on L-arabinose, sucrose, D-xylose, D-mannitol, rhamnose, and raffinose.

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* or *Streptomyces* species.

Source: not known.

DNA G+C content (mol%): not known.

Type strain: ATCC 49055, DSM 43929, NBRC 14789, JCM 9868, NRRL B-16109.

Sequence accession no. (16S rRNA gene): U93324.

12. **Kitasatospora niigatensis** Tajima, Takahashi, Seino, Iwai and Ōmura 2001, 1770[VP]

ni.i.gat.en′sis. N.L. fem. adj. *niigatensis* of or belonging to Niigata, the city in Japan where the species originated.

The spore chains are straight and flexuous, with 20 or more rod-shaped, smooth-surfaced spores (1.0–1.1 × 0.5 µm) per chain. Submerged spores are formed in liquid culture. Produces ivory to brownish-gray vegetative mycelium and brownish white to purplish gray aerial mycelium on yeast extract-malt extract agar, oatmeal agar, glycerol-asparagine agar, and sucrose-nitrate agar. Soluble pigments, including melanin, are not produced. The strain is positive for reduction of nitrate, peptonization of milk, and hydrolysis of starch. D-Glucose, L-arabinose, and D-xylose are utilized for growth, but raffinose, melibiose, D-mannitol, D-fructose, D-rhamnose, inositol, sucrose, and cellulose are not utilized. The cell wall contains both *meso*- and LL-A_2pm. Whole-cell hydrolysates contain galactose, mannose, and ribose, but lack arabinose and xylose. Phosphatidylethanolamine and phosphatidylinositol are contained in the polar lipid fraction. MK-9(H_6) and MK-9(H_8) are predominant menaquinones. The *N*-acyl type is the acetyl type. The temperature range for growth is 15–41°C. The strain is resistant to novobiocin at 100 µg/ml.

The type strain shows its highest sequence similarities to the following *Kitasatospora* species: *Kitasatospora cineracea*, AB022875, 100%; *Kitasatospora phosalacinea*, AB022869, 99.1%; *Kitasatospora setae*, AB022868, 99.1%; *Kitasatospora griseola*, AB022870, 99%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: isolated from soil from Niigata, Japan.

DNA G+C content (mol%): 73.5.

Type strain: SK-3406, NBRC 16453, JCM 10916, NRRL B-24135.

Sequence accession no. (16S rRNA gene): AB249960.

13. **Kitasatospora nipponensis** Groth, Rodríguez, Schüetze, Schmitz, Leistner and Goodfellow 2004, 2127[VP]

nip.pon.en′sis. N.L. fem. adj. *nipponensis* of or pertaining to Nippon, the native name for Japan, the origin of the soil from which the type strain was isolated.

Spore chains are open spirals, long straight loops and hooks with 20 or more cylindrical, smooth-surfaced spores (1.1–1.6 × 1.2–2.3 µm) per chain. Submerged spores are formed in liquid culture. Produces a yellowish- or reddish-brown substrate mycelium and a gray aerial spore mass on glycerol-asparagine, inorganic salts-starch, oatmeal, and yeast extract-malt extract agars. A purple soluble pigment is formed on oatmeal agar, but melanoid pigments are not produced on peptone-yeast extract-iron and tyrosine agars. Temperature range for growth is 10–32°C (optimum 25–28°C); growth does not occur at 6 or 37°C. Good growth is observed at pH 5.0–8.0; growth does not occur at pH 4.5 or above pH 8.5. The cell wall contains *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated and whole-organism hydrolysates contain galactose, mannose, ribose, and glucose. The major polar lipids are phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol, phosphatidylinositol mannosides, and an unknown phospholipid. The predominant fatty acids are $C_{16:0}$ iso (38%) and $C_{15:0}$ iso (10%); mycolic acids are absent. The major menaquinone is MK-9(H_6) (74%).

The type strain shows its highest sequence similarity to following *Kitasatospora* species: *Kitasatospora kifunensis*, AB022874, 99.1%; *Kitasatospora azatica*, U93312, 99.1%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* species, but shows its highest sequence similarities to the following *Streptomyces* species: *S. herbaricolor*, AB184801, 99%; *S. indigoferus*, AB184214, 99%.

Source: the type strain was isolated from a soil sample collected at Kumagura, Japan.

DNA G+C content (mol%): not known.

Type strain: 2148-013, HKI 0315, DSM 44787, JCM 13004, NBRC 101836, NCIMB 13975.

Sequence accession no. (16S rRNA gene): AY442263.

14. **Kitasatospora paracochleata** corrig. (Nakagaito, Yokota and Hasegawa 1992b) Zhang, Wang and Ruan 1997, 1053[VP] (*Streptomyces paracochleatus* Nakagaito, Yokota and Hasegawa 1992b, 118)

pa.ra.co.chle.a′ta. Gr. prep. *para* beside, alongside of, resembling; L. fem. adj. *cochleata* a specific epithet; N.L. fem. adj. *paracochleata* similar to *Kitasatospora cochleata*.

Mature spore chains on aerial mycelia are long, forming spirals on glycerol-asparagine agar, tyrosine agar, oatmeal agar, glucose-asparagine agar, and water agar. Spores are cylindrical with a smooth surface. The color of vegetative mycelia is grayish brown. The color of aerial mycelia is gray.

Melanoid pigments are produced on tyrosine agar. Brown soluble pigments are produced on yeast extract-malt extract agar. Nitrate is reduced, starch is hydrolyzed, and gelatin is not liquefied. Milk is peptonized but not coagulated. D-Glucose and D-fructose are utilized, but L-arabinose, D-mannitol, D-xylose, rhamnose, raffinose, iso-inositol, and sucrose are not or poorly utilized. The temperature range for growth is 11–39°C. The concentration of NaCl at which growth occurs is less than 3%. The cell wall contains both LL- and *meso*-A_2pm and glycine. Galactose, rhamnose, and a trace of madurose are detected as whole-cell sugars. The phospholipid pattern is type II. MK-9(H_6) and MK-9(H_8) are detected.

The type strain shows its highest sequence similarities to the following *Kitasatospora* species: *Kitasatospora cochleata*, U93316, 99.5%; *Kitasatospora griseola*, AB022870, 99.2%; *Kitasatospora cystarginea*, U93318, 99%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: not known.

Sequence accession no. (16S rRNA gene): U93328.

15. **Kitasatospora paranensis** Groth, Rodríguez, Schüetze, Schmitz, Leistner and Goodfellow 2004, 2128[VP]

pa.ra.nen′sis. N.L. fem. adj. *paranensis* of or pertaining to Parana, a state of Brazil, the origin of the soil from which the type strain was isolated.

Spore chains are long, straight to flexuous with 20 or more cylindrical, smooth-surfaced spores (1.1–1.4 × 1.2–2.1 μm) per chain. Submerged spores are rarely formed in liquid culture. Produces a yellowish-brown to dark brown substrate mycelium and a gray aerial spore mass on glycerol-asparagine, inorganic salts-starch, oatmeal, and yeast extract-malt extract agars. Soluble pigments are not formed, but melanoid pigments are produced on peptone-yeast extract-iron and tyrosine agars. Temperature range for growth is 10–37°C (optimum 25–28°C); growth does not occur at 6 or 40°C. Good growth is observed at pH 5.0–9.0; growth does not occur at either pH 4.0 or pH 9.5. The cell wall contains both *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated and whole-organism hydrolysates contain galactose, mannose, and glucose. The polar lipids are phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol mannosides, phosphatidylserine, and an unknown phospholipid. The predominant fatty acids are $C_{16:0}$ iso (19%), $C_{15:0}$ anteiso (16%), and $C_{16:0}$ (14%); mycolic acids are absent. The major menaquinone is MK-9(H_6) (53%), with minor components MK-9(H_4) (22%) and MK-9(H_2) (14%).

The type strain shows its highest sequence similarities to the following *Kitasatospora* species: *Kitasatospora terrestris*, AY442266, 99.2%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: the type strain was isolated from rhizosphere soil of *Maytenus ilicifolia*, Contenda, Parana State, Brazil.

DNA G+C content (mol%): not known.

Type strain: 2292-041, HKI 0190, DSM 44788, JCM 13005, NBRC 101837, NCIMB 13976.

16. **Kitasatospora phosalacinea** corrig. Takahashi, Iwai and Ōmura 1985, 535[VP] (Effective publication: Takahashi, Iwai and Ōmura 1984, 384.)

pho.sa.la.ci′ne.a. N.L. fem. adj. *phosalacinea* pertaining to phosalacine (an antibiotic produced by the organism).

Spore chain morphology *Rectiflexibiles* type. Color of vegetative mycelia is pale yellowish-brown on most media. Aerial mass color is white or light gray on oatmeal and inorganic salts-starch agars. Forms yellowish-brown diffusible pigment on some media. Can grow in NaCl at a concentration up to 2.0%. The temperature range for growth is 15–42°C. Cell wall contains both *meso*- and LL-A_2pm. Whole-cell hydrolysates contain galactose, but lack arabinose, madurose, and xylose. Produces phosalacine, a herbicidal antibiotic; activity *in vitro* against *Bacillus subtilis* on a synthetic medium, which is reversed by glutamine.

The type strain shows its highest sequence similarities to the following *Kitasatospora* species: *Kitasatospora cineracea*, AB022875, 99.2%; *Kitasatospora niigatensis*, AB022876, 99.1%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: soil.

DNA G+C content (mol%): 66.6.

Type strain: KA-338, DSM 43860, NBRC 14372, JCM 3340, NRRL B-16230, VKM Ac-2006.

Sequence accession no. (16S rRNA gene): M55223.

17. **Kitasatospora putterlickiae** Groth, Schütze, Boettcher, Pullen, Rodriguez, Leistner and Goodfellow 2003, 2037[VP]

put.ter.lic′ki.ae. N.L. gen. n. *putterlickae* of the plant genus *Putterlickia*.

Spore chains are straight to flexuous (*Rectiflexibiles*), with 20 or more cylindrical, smooth-surfaced spores (1.6–2.5 × 1.0–1.5 μm) per chain. Submerged spores are formed in liquid culture. Produces a dark-brown substrate mycelium and a dark-gray aerial spore-mass on glycerol-asparagine and yeast extract-malt extract agars. Brown soluble pigments are formed on oatmeal and yeast extract-malt extract agars and melanoid pigments are formed on peptone-yeast extract-iron and tyrosine agars. Nitrate is reduced to nitrite, gelatin is liquefied, milk is peptonized, casein is degraded, and H_2S is weakly produced. Starch is not hydrolyzed. Alkaline phosphatase, esterase (C4), esterase lipase (C8), leucine arylamidase, acid phosphatase, β-galactosidase and β-glucosidase are produced, but *N*-acetyl-β-glucosamidase, α-chymotrypsin, cystine arylamidase, α-fucosidase, α-galactosidase, α-glucosidase, β-glucuronidase, lipase (C14), α-mannosidase, naphthol-AS-BI-phosphohydrolase, trypsin and valine arylamidase are not. D(+)-fructose (weak), D(+)-glucose, and D(−)-sucrose (weak) are used as sole sources of carbon for energy and growth, but L(+)-arabinose, cellulose, iso-inositol, D(−)-mannitol, D(+)-raffinose, L(+)-rhamnose, and D(+)-xylose are not. Temperature range for growth is 10–37°C (optimum is between 28 and 32°C); growth does not occur at either 6 or 40°C. Good growth occurs at pH 5–9; growth does not occur at pH 4.5 or above 9.5. Growth is inhibited by ampicillin (10 μg/ml), chloramphenicol (30 μg/ml), ciprofloxacin (5 μg/ml), imipenem (10 μg/ml), kanamycin sulfate (30 μg/ml), methicillin (5 μg/ml, weak), novobiocin (2.5 μg/ml), oxytetracycline hydrochloride (30 μg/ml), penicillin G (10 IU), polymyxin B (300 IU, weak), rifampin (30 μg/ml), streptomycin sulfate (10 μg/ml), vancomycin hydrochloride (30 μg/ml), and nalidixic acid (50 μg/ml), but not by lincomycin hydrochloride (2 μg/ml), norfloxacin (10 μg/ml), or sulfonamide (200 μg/ml). NaCl is tolerated up to a concentration of 3.5% (w/v). Resistance is shown to polyvalent *Streptomyces* phage S7. Whole cell chemistry reveals the presence of both *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated. Whole-organism hydrolysates contain galactose, madurose, mannose, and

rhamnose, and the major polar lipids are diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. Predominant fatty acids are $C_{16:0}$, $C_{16:0}$, and $C_{15:0}$ iso; mycolic acids are absent. Major menaquinones are tetra- and hexahydrogenated with nine isoprene units.

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* or *Streptomyces* species.

Source: isolated from the rhizosphere of *Putterlickia verrucosa.*

DNA G+C content (mol%): 66.6.

Type strain: F18-98, DSM 44665, JCM 12393, NBRC 100917, NCIMB 13932.

Sequence accession no. (16S rRNA gene): AY189976.

18. **Kitasatospora sampliensis** Mayilraj, Krishnamurthi, Saha and Saini 2006, 521[VP]

sam.pli.en′sis. N.L. fem. adj. *sampliensis* pertaining to Sampli village, Punjab State, India, where the type strain was isolated.

Spore chain morphology is *Rectiflexibiles* with 10 or more smooth-surfaced spores per chain. Produces pale-gray, dark-gray, or dark-gray-brown substrate mycelium and a pale-gray or dark-gray aerial mycelium on almost all ISP media. Dark-brown or dark-gray soluble pigments are formed on ISP 2, ISP 3, ISP 6, ISP 7, *Streptomyces* agar, actinomycetes isolation agar, and Sabouraud glucose agar. Melanin is produced on peptone-yeast extract-iron and tyrosine agar. Nitrate is reduced to nitrite, casein is not degraded, starch is not hydrolyzed, and gelatin is not liquefied. Positive for utilization of L-arabinose, L-rhamnose, D-fructose, D-mannitol, raffinose, D-sucrose, and D-xylose as sole carbon and energy sources. Can grow in NaCl at a concentration up to 2.5%, but not at 3.0% or above. Optimum growth is observed at pH 7.0–8.0 and at 30°C. Cell wall contains both *meso*- and LL-A_2pm. The *N*-acyl type of muramic acid of the peptidoglycan is acetyl. Major fatty acids are $C_{16:0}$ (16.48%), $C_{15:0}$ iso (20.07%), $C_{16.0}$ (10.94%), $C_{17:0}$ iso (12.54%), $C_{15:0}$ anteiso (9.55%), and $C_{17:0}$ anteiso (9.36%). Whole-cell sugars are galactose, glucose, mannose, and ribose. The polar lipids are phosphatidylinositol, phosphatidylethanolamine, diphosphatidylglycerol, and phosphatidylinositol mannosides. The major menaquinone is MK-9(H6).

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* or *Streptomyces* species.

Source: the type strain was isolated from a sugar-cane field soil sample collected from Sampli village, Punjab state, India.

DNA G+C content (mol%): 76.5.

Type strain: VT-36, DSM 44898, JCM 13010, NBRC 102069, MTCC 6546.

Sequence accession no. (16S rRNA gene): AY260167.

19. **Kitasatospora terrestris** Groth, Rodriguez, Rodríguez, Schüetze, Leistner and Goodfellow 2004, 2128[VP]

ter.res′tris. L. fem. adj. *terrestris* of the earth, terrestrial.

Spore chains are straight, hooked and spiral with 20 or more cylindrical, smooth-surfaced spores (1.1–1.5 × 1.3–2.8 μm) per chain. Submerged spores are formed in liquid culture. Produces a yellowish-brown to dark brown substrate mycelium and a gray aerial spore mass on glycerol-asparagine, inorganic salts-starch, oatmeal, and yeast extract-malt extract agars. Soluble pigments are not formed. The formation of melanoid pigments is weak on peptone-yeast extract-iron, and tyrosine agars. Temperature range for growth is 15–40°C (optimum 28–32°C); growth does not occur at 10°C or 42°C. pH range for good growth is pH 5.0–9.0; growth does not occur at pH 4.5 or at pH 9.5. The cell wall contains *meso*- and LL-A_2pm; the muramic acid moiety is *N*-acetylated and whole-organism hydrolysates contain galactose, mannose, and glucose. The polar lipids are phosphatidylethanolamine, diphosphatidylglycerol, phosphatidylglycerol (traces), phosphatidylinositol, phosphatidylinositol mannosides, phosphatidylserine, and an unknown glycolipid. The predominant fatty acids are $C_{16:0}$ iso (21%), $C_{15:0}$ iso (16%), and $C_{15:0}$ anteiso (10%); mycolic acids are absent. The major menaquinone is MK-9(H_6) (76%).

The type strain shows its highest sequence similarity to *Kitasatospora paranensis*, AY442268, 99.2%. It does not show any sequence similarities over 99% to any *Streptacidiphilus* or *Streptomyces* species.

Source: the type strain was isolated from a soil sample of the roots of *Maytenus aquifolia*, Ribeirao Preto, Brazil.

DNA G+C content (mol%): not known.

Type strain: 2293-012, HKI 0186, DSM 44789, JCM 13006, NBRC 101838, NCIMB 13977.

Sequence accession no. (16S rRNA gene): AY442266.

20. **Kitasatospora viridis** Liu, Rodríguez, Wang, Cui, Huang, Quintana and Goodfellow 2005a, 709[VP]

vi′ri.dis. L. fem. adj. *viridis* green, referring to the production of a green aerial spore mass.

Non-acid–alcohol-fast, nonmotile actinomycete that forms an extensively branched, light-yellow substrate mycelium and a greenish aerial spore mass on acidified oatmeal agar. Aerial hyphae differentiate into long, spiral chains of smooth-surfaced, cylindrical spores (1.0–1.2 × 0.7–0.8 μm). Starch is degraded, but not adenine, guanine, hypoxanthine, xanthine, or xylan. Adonitol, cellobiose, dextran, D-galactose, D-gluconic acid, D-glucose, inulin, D-lactose, maltose, D-mannose, melezitose, melibiose, D-salicin, D-sorbitol, trehalose, and xylitol are used as sole carbon sources for energy and growth, but not glycerol, *myo*-inositol, or xylan (all at 1%, w/v). Similarly, 2-aminoethanol, α-DL-aminobutyric acid, L-alanine, L-arginine, L-cysteine, L-glutamic acid, L-histidine, L-isoleucine, L-phenylalanine, L-threonine, L-valine, sodium oxalate, and sodium pyruvate are used as sole carbon sources, but not adipic acid or L-aspartic acid (all at 0.1%, w/v). 2-Aminoethanol, L-alanine, L-arginine, L-isoleucine, and L-phenylalanine are used as sole sources of carbon and nitrogen for energy and growth. Growth occurs at 10–37°C, but not at 4 or 45°C. The pH range for growth is pH 4–7.0. Growth occurs in the presence (μg/ml) of amikacin (32), amoxycillin (32), ampicillin (32), cefalexin (32), cephaloridine (64), clindamycin (8), doxycycline hydrochloride (32), fusidic acid (16), gentamicin sulfate (16), kanamycin sulfate (16), lincomycin hydrochloride (16), midecamycin (4), neomycin sulfate

(32), penicillin G (16 IU), streptomycin sulfate (16), tetracycline hydrochloride (32), and tobramycin sulfate (16), but is inhibited by erythromycin (8) and novobiocin (8). NaCl is tolerated up to a concentration of 10%. Cell wall contains both *meso*- and LL-A_2pm and *N*-acetylated muramic acid, and whole-organism hydrolysates are rich in galactose and glucose. The major polar lipids are diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, and phosphatidylinositol mannosides. The predominant isoprenologs are hexa- (76%) and octa- (17%) hydrogenated menaquinones with nine isoprene units. The major fatty acids are $C_{15:0}$ iso (19%), $C_{15:0}$ anteiso (18%), $C_{16:0}$ iso (18%), $C_{16:0}$ (22%), and $C_{17:0}$ anteiso (8%).

The type strain does not show any sequence similarities over 99% to other *Kitasatospora* species, or to any *Streptacidiphilus* or *Streptomyces* species.

Source: the type strain was isolated from a soil sample taken from the roots of *Camellia oleifera* in Jiangxi Province, China.

DNA G+C content (mol%): not known.

Type strain: 52108a, AS 4.1878, DSM 44826, JCM 14111.

Sequence accession no. (16S rRNA gene): AY613990.

Genus *incertae sedis* II. **Streptacidiphilus** Kim, Lonsdale, Seong and Goodfellow 2003a, 1219^VP (Effective publication: Kim, Lonsdale, Seong and Goodfellow 2003b, 115.)

Peter Kämpfer

Strep.ta.ci.di′phi.lus. Gr. adj. *streptos* pliant, easily twisted; N.L. neut. n. *acidum* (from L. adj. *acidus -a -um* sour) an acid; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. masc. n. *Streptacidiphilus* twisted, acid-loving.

Aerobic. Gram-stain-positive, non-acid–alcohol-fast actinomycetes that form an intensively branched, non-fragmenting mycelium. The aerial mycelium at maturity carries long chains of spores. Discrete leathery or lichenoid colonies are formed. Produce a range of pigments that are responsible for the color of the substrate and aerial mycelium. Colored diffusible pigments may be formed. Chemo-organotrophic, having an oxidative type of metabolism. Use a wide range of carbon compounds as sole sources of carbon for energy and growth. Most strains grow between pH 3.5 and 6.0 with an optimum around pH 5, and at temperatures between 15 and 30°C. LL-A_2pm is the major diamino acid in the peptidoglycan layer. Contains major amounts of galactose and rhamnose in whole-organism hydrolysates, hexa- and octa-hydrogenated menaquinones with nine isoprene units as predominant isoprenologs, is rich in saturated, iso- and anteiso-fatty acids, and produces complex polar lipid patterns that contain diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, and phosphatidylinositol mannosides. The organism is widely distributed in acidic soil and litter.

DNA G+C content (mol%): 70–72.

Type species: **Streptacidiphilus albus** Kim, Lonsdale, Seong and Goodfellow 2003a, 1219^VP (Effective publication: Kim, Lonsdale, Seong and Goodfellow 2003b, 115.).

Further descriptive information

The genus *Streptacidiphilus* was proposed by Kim et al. (2003b) for acidophilic actinomycetes isolated from acidic soils and litter. Acidophilic actinomycetes grow at pH 3.5–6.5 with optimum growth at pH 4.5–5.5. They produce anti-fungal compounds, are involved in the turnover of organic matter at low pH values (Goodfellow and Williams, 1983; Williams et al., 1984b), and form diastases and chitinases with pH optima below those for neutrophilic streptomycetes (Williams, 1978; Williams and Robinson, 1981). In an extensive numerical taxonomic study, Lonsdale (1985) found that acidophilic actinomycetes with streptomycete-like properties were heterogeneous and formed distinct clusters, which could be clearly differentiated using several phenotypic tests. These findings were supported by Goodfellow and Simpson (1987), and Seong et al. (1993, 1995).

Representatives of clusters 2, 4, and 10 delineated in the study of Lonsdale (1985) were described as nomenspecies of the novel genus *Streptacidiphilus*, namely *Streptacidiphilus albus*, *Streptacidiphilus neutrinimicus*, and *Streptacidiphilus carbonis* by Kim et al. (2003b). A fourth species, *Streptacidiphilus jiangxiensis*, isolated from the acidic rhizosphere soil, was described by Huang et al. (2004a) and, subsequently, four additional species, *Streptacidiphilus oryzae*, *Streptacidiphilus anmyonensis*, *Streptacidiphilus rugosus*, and *Streptacidiphilus melanogenes*, were described (Cho et al., 2008; Wang et al., 2006) bringing the total number of validly published names to eight. Representatives of each of these species forms a distinct line in the 16S rRNA *Streptomycetaceae* gene tree (Kim et al., 2003b; Cho et al., 2008; Figure 339). On the basis of 16S rRNA gene sequence data, all of the species are grouped together showing high similarities. However, they are also very similar to members of the genera *Streptomyces* and *Kitasatospora*, i.e. they produce aerial mycelia with long chains of spores, they have LL-A_2pm as the major wall diamino acid, contain hexa- and octa-hydrogenated menaquinones with nine isoprene units as predominant isoprenologs, are rich in saturated, iso- and anteiso-fatty acids, and produce complex polar lipid patterns that contain major amounts of diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, and phosphatidylinositol mannosides. *Streptacidiphilus* strains differ from *Kitasatospora* and *Streptomyces* strains as they contain major amounts of galactose and rhamnose in whole-organism hydrolysates. Because of the high phenotypic similarities to *Streptomyces* and *Kitasatospora* they are clearly a sister taxon of *Streptomyces*. For this reason, the genus is treated here as a genus *incertae sedis*. Phenotypic properties that distinguish between *Streptacidiphilus* species are given in Table 274.

Enrichment and isolation procedures

Kim et al. (2003b) reported the isolation of 18 strains of streptoacidiphili on acidified starch agar plates supplemented with cycloheximide and nystatin (each 50 µg/ml) using the isolation procedure described by Goodfellow and Dawson (1978). Huang et al. (2004a) isolated *Streptacidiphilus jiangxiensis* by plating acidic rhizosphere soil suspensions, prepared using a differential

centrifugation procedure (Wang et al., 2003), onto an acidified selective isolation medium containing sucrose, aspartate, and L-glutamate as carbon sources. Acidified starch-casein-nitrate agar (Küster and Williams, 1964a) can also be used (Wang et al., 2006) in combination with differential centrifugation, as described by Sembiring et al. (2000). Cho et al. (2006) reported a further procedure for the isolation of acidophilic actinobacteria from soil.

Maintenance procedures

Kim et al. (2003b) reported that short-term storage could be achieved by growing strains on acidified modified Bennett's agar (Jones, 1949). Acidified inorganic salts-starch (ISP medium 4; Shirling and Gottlieb, 1966) and acidified oatmeal (ISP medium 3; Shirling and Gottlieb, 1966) agar can also be used for this purpose. Lyophilization, storage in liquid nitrogen, and freezing in glycerol can be used for long-term preservation. Glycerol suspensions are prepared by scraping aerial growth or substrate mycelium or both from heavily inoculated plates and making heavy suspensions in 3 ml aqueous glycerol in small (e.g. bijoux) bottles, which are stored at −20°C.

Differentiation of the genus *Streptacidiphilus* from other genera

Members of the family *Streptomycetaceae* are morphologically and chemically homogeneous (Table 263). In addition, identification of most species is difficult because, in many instances, only one (the type) or a few strains have been examined. *Streptacidiphilus* may be distinguished from the other genera in the family *Streptospoangiaceae* by slight differences in cell-wall peptidoglycan composition and by growth at low pH values, as well as by 16S rRNA gene sequencing (Table 263).

List of species of the genus *Streptacidiphilus*

1. **Streptacidiphilus albus** Kim, Lonsdale, Seong and Goodfellow 2003a, 1219[VP] (Effective publication: Kim, Lonsdale, Seong and Goodfellow 2003b, 115.)

al′bus. L. masc. adj. *albus* white.

Aerial hyphae differentiate into long flexuous chains of spores (0.6 × 1.0 µm); the spore surface is smooth. Cream-colored colonies that carry moderate to abundant white aerial hyphae are formed on acidified modified Bennett's agar. The underside of colonies is either brown or cream-colored; diffusible brown pigments may be formed. Xanthine is degraded. L-Arabinose, D-galactose, D-glucose, glycerol, glycogen, D-lactose, maltose, melibiose, raffinose, D-ribose, and trehalose (all at 1%, w/v), and L-alanine, L-arginine, L-aspartic acid, L-glutamic acid, L-histidine, L-phenylalanine, sodium pyruvate, and sodium succinate (all at 0.1%, w/v) are used as sole carbon sources for energy and growth, but not acetamide, D-amygdalin, *meso*-erythritol, *myo*-inositol, inulin, melezitose, methyl α-D-glucoside, D-sorbitol (all at 1%, w/v), or *p*-hydroxybenzoic acid, sodium adipate, sodium hippurate, sodium malate, sodium oxalate, or sodium propionate (at 0.1%, w/v). L-Glutamic acid is metabolized as sole carbon and nitrogen source but not acetamide or L-isoleucine. Growth occurs between 10 and 25°C, between pH 3.5 and 6.0, and in the presence (all at µg/ml) of cephaloridine hydrochloride (2), gentamicin sulfate (32), lincomycin hydrochloride (16), neomycin sulfate (32), oleandomycin sulfate (4), penicillin G (16), streptomycin sulfate (16), tobramycin sulfate (4), bismuth citrate (10), cadmium acetate (50), cobalt chloride (10), copper sulfate (10), crystal violet (1), ferrous sulfate (50), lead acetate (100), manganese sulfate (100), potassium tellurite (50), thallous acetate (1), and zinc sulfate (100). Growth does not occur at 30°C, or in the presence of chlortetracycline hydrochloride (2), demeclocycline hydrochloride (2), vancomycin hydrochloride (2), or crystal violet (10).

The type strain does not show any sequence similarities over 99% with other *Streptacidiphilus* species, or with *Kitasatospora* or *Streptomyces* species.

Source: the type strain was isolated from litter layers in a spruce forest soil.

DNA G+C content (mol%): not known.

Type strain: JL83, DSM 41753, JCM 12363, KCTC 9910, NBRC 100918.

Sequence accession no. (16S rRNA gene): AF074415.

2. **Streptacidiphilus anmyonensis** Cho, Han, Ko and Kim 2008, 1568[VP]

an.myon.en′sis. N.L. masc. adj. *anmyonensis* of or belonging to Anmyon, where the organism was isolated.

Aerial hyphae differentiate into long flexuous chains of spores (0.6 × 0.9 µm); the spore surface is smooth. Forms cream-colored colonies that carry moderate to abundant, white to grayish-white aerial hyphae on acidified oatmeal, inorganic salt-starch, yeast extract-malt extract and modified Bennett's agar plates. The substrate mycelium is brownish gray to brown on acidified oatmeal and yeast extract-malt extract agars, but cream-colored on the other two agars. Soluble pigments are not produced on any of the above-mentioned media. Starch and Tween 80 are degraded, but xanthine, and Tweens 20 and 40 are not. Glycerol, D-gluconic acid, D(+)-glucosamine hydrochloride, *myo*-inositol, melibiose, D-sorbitol, sucrose, D(+)-xylose (all at 1%, w/v), and L-arginine (at 0.1%, w/v) are used as sole carbon sources for energy and growth, but L-aspartic acid and sodium oxalate (all at 0.1%, w/v) are not. L-Isoleucine is used as sole nitrogen source. Growth occurs at pH 3.0–8.0 and between 28 and 35°C. Chemotaxonomic properties are typical of the genus *Streptacidiphilus*. The major fatty acids are $C_{15:0}$ iso (18.4% of the total fatty acid composition), $C_{15:0}$ anteiso (11.4%), $C_{16:0}$ iso (19.1%), *n*-$C_{16:0}$ (14.7%), $C_{17:0}$ iso (7.4%), and $C_{17:0}$ anteiso (7.5%). Contains hexa- and octahydrogenated menaquinones with nine isoprene units [MK-9(H_6) and MK-9(H_8), 24.1% and 55.8% of the total composition, respectively] as predominant isoprenologs. The diamino acid of the peptidoglycan is LL-A_2pm (89% of the total A_2pm composition), although minor amounts of the *meso*-isomer (11%) are also detected.

The type strain shows its highest sequence similarities to the following: *Streptacidiphilus* species: *Streptacidiphilus jiangxiensis*, AB249948, 99.6; *Streptacidiphilus melanogenes*, DQ994689, 99.3%. It does not show any sequence similarities over 99% to any *Kitasatospora* or *Streptomyces* species.

Source: isolated from *Pinus* soils Anmyeon, near coastal areas in Tae-An, Chungnam, Republic of Korea.

DNA G+C content (mol%): not known.

Type strain: AM-11, NBRC 103185, KCTC 19278.

Sequence accession no. (16S rRNA gene): DQ904546.

3. **Streptacidiphilus carbonis** Kim, Lonsdale, Seong and Goodfellow 2003b, 1219[VP] (Effective publication: Kim, Lonsdale, Seong and Goodfellow 2003b, 114.)

car′bo.nis. L. n. *carbo -onis* coal; L. gen. n. *carbonis* of/from coal.

Aerial hyphae differentiate into long flexuous chains of spores (0.6 × 1.0 µm); the spore surface is smooth. Cream-colored colonies form sparse to abundant white aerial hyphae on acidified modified Bennett's agar. The underside of colonies is cream-colored. Elastin is not degraded. L-Arabinose, D-fructose, D-gluconic acid, glycerol, glycogen, *myo*-inositol, inulin, D-raffinose, L-rhamnose (all at 1%, w/v), sodium pyruvate, and sodium succinate (all at 0.1%, w/v) are used as sole carbon sources for energy and growth, but not D-amygdalin, melezitose, methyl α-D-glucoside, D-ribose, D-sorbitol (all at 1%, w/v), sodium adipate, L-isoleucine, or sodium oxalate (all at 0.1%, w/v). L-Alanine, L-arginine, L-aspartic acid, L-glutamic acid, and L-phenylalanine are used as sole carbon and nitrogen sources, but not 2-aminoethanol or L-isoleucine. Grows between 15 and 30°C, at pH 3.5–6.0, and in the presence (all at µg/ml) of gentamicin sulfate (4), lincomycin hydrochloride (16), neomycin sulfate (32), oleandomycin phosphate (4), tobramycin sulfate (4), bismuth citrate (1), cadmium acetate (10), cobalt chloride (10), copper sulfate (10), crystal violet (1), ferrous sulfate (10), lead acetate (50), manganese sulfate (50), thallous acetate (1), and zinc sulfate (100), but not with cephaloridine (2), demeclocycline hydrochloride (2), penicillin G (16), streptomycin sulfate (16), vancomycin hydrochloride (2), cadmium acetate (50), cobalt chloride (50), crystal violet (10), ferrous sulfate (100), lead acetate (100), potassium tellurite (50), or thallous acetate (100).

The type strain does not show any sequence similarities over 99% to other *Streptacidiphilus* species, or to any *Kitasatospora* or *Streptomyces* species.

Source: the type strain was isolated from reclaimed acid coal mine waste.

DNA G+C content (mol%): not known.

Type strain: JL415, DSM 41754, JCM 12364, KCTC 9912, NBRC 100919.

Sequence accession no. (16S rRNA gene): AF074412.

4. **Streptacidiphilus jiangxiensis** Huang, Cui, Wang, Rodriguez, Quintana, Goodfellow and Liu 2005, 1743[VP] (Effective publication: Huang, Cui, Wang, Rodriguez, Quintana, Goodfellow and Liu 2004a, 162.)

ji.ang.xi.en′sis. N.L. masc. adj. *jiangxiensis* of or pertaining to Jiangxi Province, South China, the source of the isolates.

Aerial hyphae differentiate into long *Rectiflexibiles* chains of spores (0.6 × 0.9–1.0 µm) which have smooth surfaces. The organism forms lichenoid colonies that carry moderate to abundant, white to grayish-white aerial hyphae on acidified oatmeal, inorganic salts-starch, modified Bennett's, and yeast extract-malt extract agars. The substrate mycelium is cream-colored on acidified oatmeal agar, stray yellow or Dresden brown on the other three agars. Soluble pigments are not produced on the media cited above, nor are melanin pigments formed on peptone-yeast extract-iron agar. Guanine, hypoxanthine, Tweens 40, 60, and 80, and xanthine are not degraded. Adonitol, D(+)-cellobiose, dextran, D(−)-fructose, D(+)-mannitol, D(+)-mannose, salicin, D(+)-sucrose, xylan, xylitol, D(+)-xylose (all at 1%, w/v), 2-aminoethanol, L-cystine, L-glutamic-acid, L-isoleucine, sodium oxalate, L-threonine, and L-valine (all at 0.1%, w/v) are used as sole carbon sources for energy and growth, but not adipic acid, aminobutyric acid, L-arginine, L-aspartic acid, or L-histidine (all at 0.1%, w/v). L-Alanine, 2-aminoethanol, L-arginine, L-isoleucine, and L-phenylalanine are used as sole carbon and nitrogen sources, but not aspartic acid. Growth occurs between pH 3.5–6.5 and between 15 and 35°C. Sensitive to ampicillin (10 µg/ml), carbenicillin (100), chloramphenicol (30), clarithromycin (15), gentamicin sulfate (10), kanamycin sulfate (30), midecamycin (15), minocycline hydrochloride (30), novobiocin (5), penicillin G (16), rifampin (5), streptomycin sulfate (16), and tobramycin sulfate (10). Chemotaxonomic properties are typical of the genus *Streptacidiphilus*. The predominant fatty acids are $C_{15:0}$ iso (10.8–13.2%), $C_{15:0}$ anteiso (14.7–17.5%), $C_{16:0}$ iso (18.3–22.2%), and $C_{16:0}$ (25.9–30.4%).

The type strain shows its highest sequence similarities to the following *Streptacidiphilus* species: *Streptacidiphilus anmyonensis*, DQ904546, 99.6%; *Streptacidiphilus melanogenes*, DQ994689, 99.1%. It does not show any sequence similarities over 99% to any *Kitasatospora* or *Streptomyces* species.

Source: isolated from rhizosphere soil of wild tea plants growing on the campus of Jiangxi Agricultural University, Jiangxi Province, China.

DNA G+C content (mol%): 70.8–71.7.

Type strain: 33214, AS 4.1857, JCM 12277, NBRC 100920.

Sequence accession no. (16S rRNA gene): AY314780.

5. **Streptacidiphilus melanogenes** Cho, Han, Ko and Kim 2008, 1569[VP]

me.la.no′ge.nes. Gr. adj. *melas -anos* black; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *melanogenes* producing black (pigment).

Aerial hyphae differentiate into long flexuous chains of spores (0.6 × 1.0 µm); the spore surface is smooth. Forms cream-colored colonies that carry moderate to abundant white aerial hyphae on acidified oatmeal, inorganic salts-starch, yeast extract-malt extract, and modified Bennett's agar plates. The substrate mycelium is brownish-gray or brown on acidified inorganic salts-starch and yeast extract-malt extract agars, but cream-colored on the other two agars. Brownish gray diffusible pigments are formed on acidified oatmeal and yeast extract-malt extract agars. Soluble pigments are not produced on the two agars. Starch, Tweens 40 and 80, and xanthine are degraded, but Tween 20 is not. Glycerol, D-gluconic acid, D(+)-glucosamine hydrochloride, *myo*-inositol, melibiose, D-sorbitol, sucrose, D(+)-xylose (all at 1%, w/v), L-arginine and sodium oxalate (all at 0.1%, w/v) are used as sole carbon sources for energy and growth, but L-aspartic acid (at 0.1%, w/v) is not. L-Isoleucine is used as nitrogen source. Growth occurs at pH 3.0–8.0 and between 28 and 35°C. Chemotaxonomic properties are typical of the genus *Streptacidiphilus*. The major fatty acids are $C_{15:0}$ iso (20.4% of the total fatty acid composition), $C_{15:0}$ anteiso (6.7%), $C_{16:0}$ iso (14.7%), *n*-$C_{16:0}$ (15.7%), $C_{17:0}$ iso (7.3%), and $C_{17:0}$ anteiso (3.8%). Contains hexa- and octahydrogenated menaquinones with nine isoprene units [MK-9(H_6) and MK-9(H_8), 18.1% and 68.6% of total composition, respectively] as predominant isoprenologs. The diamino acid of the peptidoglycan is LL-A_2pm (100% of the total A_2pm composition).

The type strain shows its highest sequence similarities to the following *Streptacidiphilus* species: *Streptacidiphilus anmyonensis*, DQ904546, 99.3; *Streptacidiphilus rugosus*, DQ904547, 99.2. It does not show any sequence similarities over 99% to any *Kitasatospora* or *Streptomyces* species.

Source: isolated from *Pinus* soils, Sambong, near coastal areas in Tae-An, Chungnam, Republic of Korea.

DNA G+C content (mol%): not known.

Type strain: SB-B34, NBRC 103184, KCTC 19280.

Sequence accession no. (16S rRNA gene): DQ994690.

6. **Streptacidiphilus neutrinimicus** Kim, Lonsdale, Seong and Goodfellow 2003a, 1219[VP] (Effective publication: Kim, Lonsdale, Seong and Goodfellow 2003b, 113.)

neu.tri.ni′mi.cus. L. adj. *neuter -tra -trum* neither or both (here for neutral pH); L. masc. n. *inimicus* an enemy, foe; N.L. n. *neutrinimicus* (nominative in apposition) enemy of the neuter pH.

Aerial hyphae differentiate into long flexuous chains of spores (0.6 × 1.0 µm); the spore surface is smooth. Cream-colored colonies form sparse to abundant white aerial hyphae on acidified modified Bennett's agar. The underside of colonies is either cream-colored or brown. Neither elastin nor xanthine is degraded. L-Arabinose, D-galactose, D-glucose, D-lactose, maltose, melibiose, glycerol, glycogen, raffinose, and trehalose (all at 1%, w/v), and L-alanine, L-arginine, L-aspartic acid, L-glutamic acid, L-histidine, L-phenylalanine, sodium pyruvate, and sodium succinate (all at 0.1%, w/v) are used as sole carbon sources for energy and growth, but not D-amygdalin, *meso*-erythritol, *myo*-inositol, inulin, melezitose, methyl α-D-glucoside, D-ribose, D-sorbitol (all at 1%, w/v), sodium adipate, *p*-hydroxybenzoic acid, L-isoleucine, sodium acetate, sodium hippurate, sodium oxalate, or sodium propionate (all at 0.1%, w/v). L-Arginine, L-aspartic acid, L-glutamic acid, and L-phenylalanine are used as sole carbon and nitrogen sources but not L-isoleucine or sodium hippurate. Growth occurs between 10 and 25°C, and at pH 3.5–5.5. Growth also occurs in the presence (all at µg) of cephaloridine hydrochloride (2), gentamicin sulfate (32), lincomycin hydrochloride (16), neomycin sulfate (32), oleandomycin phosphate (4), penicillin G (16), streptomycin sulfate (16), tobramycin sulfate (32), bismuth citrate (10), cadmium acetate (50), cobalt chloride (10), copper sulfate (10), crystal violet (1), ferrous sulfate (50), lead acetate (100), manganese sulfate (100), potassium tellurite (10), thallous acetate (10), and zinc sulfate (100), but not with chlortetracycline hydrochloride (2), demeclocycline hydrochloride (2), vancomycin hydrochloride (2), bismuth citrate (100), cadmium acetate (50), cobalt chloride (100), crystal violet (10), ferrous sulfate (100), phenol (100), or potassium tellurite (50).

The type strain does not show any sequence similarities over 99% to other *Streptacidiphilus* species, or to any *Kitasatospora* or *Streptomyces* species.

Source: the type strain was isolated from litter and mineral horizons in a spruce forest soil.

DNA G+C content (mol%): not known.

Type strain: JL206, DSM 41755, JCM 12365, KCTC 9911, NBRC 100921.

Sequence accession no. (16S rRNA gene): AF074410.

7. **Streptacidiphilus oryzae** Wang, Huang, Liu, Goodfellow and Rodríguez 2006, 1260[VP]

o.ry′za.e. L. gen. n. *oryzae* of rice, denoting the isolation of the strains from a rice field.

Aerial hyphae differentiate into long flexuous chains of spores (0.7 × 1.0 µm) with smooth surfaces. Forms brown substrate mycelium and abundant grayish-white aerial hyphae on acidified modified Bennett's, inorganic salts-starch, oatmeal, and yeast extract-malt extract agars. Golden brown diffusible pigments are formed on acidified modified Bennett's, oatmeal, and yeast extract-malt extract agars, but not on inorganic salts-starch agar. Degrades adenine, casein, starch, and uric acid, but not elastin, guanine, hypoxanthine, Tween 80, L-tyrosine, xanthine, or xylan. Nitrate is reduced. Esculin, allantoin, and urea are not hydrolyzed. L-Arabinose, D-arabi-

tol, D-cellobiose, D-fructose, D-galactose, D-glucose, glycogen, D-lactose, D-mannitol, D-mannose, raffinose, L-rhamnose, D-salicin (weak), sucrose (weak), trehalose, and D-xylose (each at 1%, w/v), and L-alanine, α-aminobutyric acid, 2-aminoethanol, L-histidine (weak), L-isoleucine (weak), L-phenylalanine, sodium fumarate (weak), sodium pyruvate (weak), L-threonine, and L-valine (each at 0.1%, w/v) are used as sole carbon sources for energy and growth, but not adonitol, dextran, methyl α-D-glucoside, ethanol, and glycine (each at 1%, w/v), or adipic acid, L-arginine, L-aspartic acid, L-cysteine, potassium nitrate, and sodium oxalate (each at 0.1%, w/v). L-Alanine, 2-aminoethanol, L-aspartic acid, L-isoleucine (weak), and L-phenylalanine (each at 0.1%, w/v) are used as sole carbon and nitrogen sources. Growth occurs at pH 3.0–6.5 and at 28 and 37°C and in the presence of (µg/ml) amoxycillin (16), fusidic acid (16), gentamicin sulfate (16, weak), lincomycin hydrochloride (16), and penicillin G (8, weak), but not in the presence of amikacin (32), amoxycillin (32), ampicillin (16, 32), cephalexin (16, 32), cephaloridine hydrochloride (32, 64), clindamycin hydrochloride (4), doxycycline hydrochloride (16), gentamicin sulfate (16), neomycin sulfate (16, 32), novobiocin (8), penicillin G (16), streptomycin sulfate (8, 16), tetracycline hydrochloride (16, 32), or lead acetate (100). Weak growth occurs in the presence of 5% (w/v) NaCl.

The type strain does not show any sequence similarities over 99% to other *Streptacidiphilus* species, or to any *Kitasatospora* or *Streptomyces* species.

Source: the type strain was isolated from a rice-field soil sample collected in Nontaburi Province, Thailand.

DNA G+C content (mol%): not known.

Type strain: TH49, CGMCC 4.2012, JCM 13271.

Sequence accession no. (16S rRNA gene): DQ208700.

8. **Streptacidiphilus rugosus** Cho, Han, Ko and Kim 2008, 1568[VP]

ru.go′sus. L. masc. adj. *rugosus* wrinkled.

Aerial hyphae differentiate into long flexuous chains of spores (0.5 × 1.2 µm); the spore surface is smooth. Forms green-colored, rugose colonies that carry moderate to abundant white aerial hyphae on acidified oatmeal, inorganic salts-starch, yeast extract-malt extract, and modified Bennett's agar plates. The substrate mycelium is cream on acidified inorganic salts-starch, yeast extract-malt extract, and modified Bennett's agars, but yellowish brown or brown on oatmeal agar. Soluble pigments are not produced on any of the abovementioned media. Starch and Tween 80 are degraded, but xanthine, and Tweens 20 and 40 are not. Glycerol, D-gluconic acid, *myo*-inositol, D-sorbitol, sucrose (all at 1%, w/v), and L-arginine and sodium oxalate (at 0.1%, w/v) are used as sole carbon sources for energy and growth, but D(+)-glucosamine hydrochloride, melibiose, D(+)-xylose (all at 1%, w/v), and L-aspartic acid (at 0.1%, w/v) are not. L-Isoleucine is used as sole nitrogen source. Growth occurs at pH 3.0–8.0 and also between 28 and 35°C. Chemotaxonomic properties are typical of the genus *Streptacidiphilus*. The major fatty acids are $C_{15:0}$ iso (15% of the total fatty acid composition), $C_{15:0}$ anteiso (14.9%), $C_{16:0}$ iso (25.4%), *n*-$C_{16:0}$ (15.6%), $C_{17:0}$ iso (3.0%) and $C_{17:0}$ anteiso (4.7%). Contains hexa- and octahydrogenated menaquinones with nine isoprene units [MK-9(H_6) and MK-9(H_8), 19.8% and 59.6% of total, respectively] as predominant isoprenologs. The diamino acid of the peptidoglycan is LL-A_2pm (94% of the total A_2pm composition), although minor amounts of the *meso*-isomer (6%) are also detected.

The type strain shows highest sequence similarity to *Streptacidiphilus melanogenes*, DQ994689, 99.2%. It does not show any sequence similarities over 99% to any *Kitasatospora* or *Streptomyces* species.

Source: isolated from *Pinus* soil, Anmyeon, near coastal areas in Tea-An, Chungnam, Republic of Korea.

DNA G+C content (mol%): not known.

Type strain: AM-16, NBRC 103186, KCTC 19279.

Sequence accession no. (16S rRNA gene): DQ904547.

Order XV. **Streptosporangiales** ord. nov.

Michael Goodfellow

Strep.to.spo.ran.gi′a.les. N.L. neut. n. *Streptosporangium* type genus of the order; suff. -*ales* ending to denote an order; N.L. fem. pl. n. *Streptosporangiales* the *Streptosporangium* order.

Aerobic, Gram-stain-positive, non-acid-fast, chemoorganotrophic actinomycete which have a wall peptidoglycan containing *meso*-diaminopimelic acid, *N*-acetylated muramic acid, and is of the A1γ type. Fatty acid profiles are complex, and mycolic acids absent. **The pattern 16S rRNA signatures consists of nucleotides at positions 127:234 (A–U), 829:857 (G–C), 830:856 (G–C), 953:1228 (U–A), 950:1231 (U–A), 955:1225 (C–G), 986:1219 (A–U) and 987:1218 (A–U)**. The order contains the families *Nocardiopsaceae*, *Streptosporangiaceae*, and *Thermomonosporaceae*.

DNA G+C content (mol%): 64–77.

Type genus: **Streptosporangium** Couch 1955, 145[AL] emend. Stackebrandt, Kroppenstedt, Jahnke, Kemmering and Gürtler 1994, 268.

Further descriptive information

The order *Streptosporangiales* was formed by elevation of the suborder *Streptosporangineae* Ward-Rainey et al. 1997 emend. Zhi et al. 2009. The families *Nocardiopsaceae*, *Thermomonosporaceae*, and *Streptosporangiaceae* form distinct clades in the 16S rRNA actinobacterial gene tree and can also be separated from one another and from other actinobacterial families by the pattern of their 16S rRNA signatures (Zhi et al., 2009). *Streptosporangiales* strains produce whole-organism hydrolysates that are rich in *meso*-diaminopimelic acid and which may or may not contain madurose, i.e. they have either a wall chemotype IIIB or IIIC *sensu* Lechevalier and Lechevalier (1970b). They contain complex mixtures of fatty acids but can be assigned to groups based on qualitative and quantitative differences in fatty acid profiles (Kroppenstedt, 1985). *Thermomonosporaceae* and *Streptosporangiaceae* strains are characterized by fatty acid patterns 3a and 3c, respectively; members of the family *Nocardiopsaceae* show greater diversity as some strains exhibit pattern 3a (*Nocardiopsis* and *Streptomonospora*) and others pattern 3e (*Thermobifida*).

Members of the three families can be distinguished on the basis of differences in menaquinone and polar lipid composition (Goodfellow et al., 1988, 1990; Kudo, 2001; Goodfellow and Quintana, 2006; Kroppenstedt and Evtushenko, 2006; Kroppenstedt and Goodfellow, 2006). *Nocardiopsaceae* strains contain menaquinones with 9, 10, or 11 isoprene units (Li et al., 2003; Zhang et al., 1998), whereas those assigned to the other two families have components with nine isoprene units (Kroppenstedt and Goodfellow, 2006; Stackebrandt et al., 1994). *Streptosporangiaceae* and *Thermomonosporaceae* strains can also be distinguished by their menaquinone profiles, as the former is characterized by the presence of major amounts of MK-9(H_2) and MK-9(H_4), saturated at sites III, and III and IV, respectively, and the latter by predominant amounts of MK-9(H_6) saturated at sites II, III, and VIII. Representatives of these taxa typically display polar lipid patterns 1 or 2 (*Thermomonosporaceae*) and IV (*Streptosporangiaceae*), according to the classification of Lechevalier et al. (1977, 1981). In contrast, *Nocardiopsaceae* strains are markedly heterogeneous as they exhibit polar lipid patterns II (*Thermobifida*), III (*Nocardiopsis*), and complex, unusual profiles (*Streptomonospora*) (Cui et al., 2001; Li et al., 2003).

Detection of chemotaxonomic markers

Members of the genera classified in the order *Streptosporangiales* can be distinguished from one another and from sporoactinomycetes assigned to other families based on the discontinuous distribution of chemotaxonomic markers, notably wall amino acids, cellular fatty acids, menaquinones, muramic acid types, sugars, and polar lipids. Standard chromatographic procedures are available for the detection of wall diamino acids (Hancock, 1994; Hasegawa et al., 1983; Staneck and Roberts, 1974), fatty acids (Kroppenstedt et al., 1990; Suzuki and Komagata, 1983) including mycolic acids (Minnikin et al., 1975), menaquinones (Collins, 1994; Kroppenstedt, 1982, 1985; Minnikin et al., 1984), muramic acid residues (Uchida and Aida, 1977; Uchida et al., 1999), and polar lipids (Minnikin et al., 1984; Suzuki et al., 1993).

Primary chemotaxonomic data can be obtained by examining whole-organism hydrolysates for the presence of the isomers of diaminopimelic acid, major diagnostic sugars, and mycolic acids using appropriate standards. The thin-layer chromatographic procedures described by Staneck and Roberts (1974) provide an easy and reliable way of detecting diagnostic amino acids and sugars. These procedures involve the application of unidimensional thin-layer chromatography to establish whether organisms contain LL-, hydroxy- or *meso*-diaminopimelic acid and major diagnostic sugars, including madurose; this sugar has almost the same R_f value as xylose but can be distinguished from the latter as it gives a yellow brown as opposed to a maroon spot. Madurose and other whole-organism sugars can also be detected by gas chromatography (Saddler et al., 1991) and high pressure liquid chromatography (Nakagaito et al., 1993; Yokota and Hasegawa, 1988). Examination of whole-organism methanolysates for the presence of mycolic acids can be achieved using the thin-layer chromatographic technique introduced by Minnikin et al. (1975).

The presence of *meso*-diaminopimelic acid and the absence of mycolic acids and diagnostic sugars other than madurose distinguishes members of the order *Streptosporangiales* from sporoactinomycetes classified in the orders *Catenulisporales*, *Corynebacteriales*, *Micromonosporales*, *Pseudonocardiales*, and *Streptomycetales*.

Strep.to.spo.ran.gi.a.ce′a.e. N.L. neut. n. *Streptosporangium* the type genus of the family, suff. *-aceae* ending to denote a family; N.L. fem. pl. n. *Streptosporangiaceae* the *Streptosporangium* family.

Aerobic, Gram-stain-positive, non-acid–alcohol-fast, chemoorganotrophic actinomycetes which form a branched, stable substrate mycelium. **When formed, aerial hyphae differentiate either into chains of two or more arthrospores or into spore vesicles that contain one to many spores which may be motile or nonmotile.** Spores are borne on the substrate hyphae when aerial mycelium is absent. Wall peptidoglycan contains *meso*-diaminopimelic acid and *N*-acetylmuramic acid and is of the A1γ type. **Lipid profiles typically contain straight, iso-, anteiso-, and 10-methyl branched fatty acids, major proportions of di- and tetrahydrogenated menaquinones with nine isoprene units, and phosphatidylethanolamine and glucosamine containing polar components. Mycolic acids are absent.** The pattern of 16S rRNA signatures consists of nucleotides at positions 440:497 (C–G), 485 (U), 501:544 (C–G), 502:543 (G–C), 833:853 (U–G), and 1355:1367 (A–U). Widely distributed in soil.

DNA G+C content (mol%): 64–77.

Type genus: **Streptosporangium** Couch 1955a, 145[AL] emend. Stackebrandt, Kroppenstedt, Jahnke, Kemmering and Gürtler 1994, 268.

Further descriptive information

Phylogeny. The 11 genera classified in the family *Streptosporangiaceae* form a distinct phyletic line in the 16S rRNA actinobacterial gene tree (Ara and Kudo, 2007; Goodfellow and Quintana, 2006; Goodfellow et al., 2005b). In addition to *Streptosporangium*, the type genus, the family contains the genera *Acrocarpospora* Tamura et al. 2000, *Herbidospora* Kudo et al. 1993, *Microbispora* Nonomura and Ohara 1957, *Microtetraspora* (Thiemann et al. 1968b) Zhang et al. 1998a, *Nonomuria* Zhang et al. 1998a (corrected to *Nonomuraea* by Chiba et al., 1998a), *Planobispora* Thiemann and Beretta 1968c, *Planomonospora* Thiemann et al. 1967, *Planotetraspora* Runmao et al. 1993 emend. Tamura and Sakane 2004, *Sphaerosporangium* Ara and Kudo 2007 (corrected to *Sphaerisporangium* by List Editor, IJSEM, 2007), and *Thermopolyspora* (*ex* Krasil'nikov and Agre 1964) Goodfellow et al. 2005b. Representatives of these taxa form distinct branches in the 16S rRNA *Streptosporangiaceae* gene tree (Figure 360) and share a pattern of 16S rRNA signatures (Zhi et al., 2009), as shown in the description of the family.

Cell morphology. At present, members of the genera classified in the family *Streptosporangiaceae* are distinguished mainly on the basis of morphological criteria (Table 275). Strains that carry one or more spores in chains (*Herbidospora*, *Microbispora*, *Microtetraspora*, *Nonomuraea*, and *Thermopolyspora*) are closely related to organisms that form spores in vesicles (*Acrocarpospora*, *Planobispora*, *Planomonospora*, *Planotetraspora*, *Sphaerisporangium*, and *Streptosporangium*). Individual spore vesicles contain a coiled chain of arthrospores formed by septation of an unbranched, spiral hypha within an expanded sporophore sheath (Vobis and Kothe, 1985). Spore formation is exogenous, hence the term "spore vesicle" is to be preferred to the original term "sporangium" (Cross, 1970; Sharples et al., 1974). Spores in spore vesicles and in spore chains are formed essentially in the same way, i.e. by a hypha bound by a sheath; sheaths either expand to form the vesicular envelope or remain around the spore chains (Lechevalier et al., 1966b; Sharples et al., 1974; Vobis and Kothe, 1985).

Chemotaxonomy. *Streptosporangiaceae* strains have many chemical markers in common (Kudo, 2001). They have either a wall chemotype IIIB or IIIC *sensu* Lechevalier and Lechevalier (1970, 1970), i.e. they produce hydrolysates that are rich in *meso*-diaminopimelic acid and may or may not contain madurose. They have *N*-acetylated muramic acid and an A1γ peptidoglycan type, are rich in unsaturated, saturated, iso- and anteiso, and 10-methyl branched fatty acids, lack mycolic acids, and typically have a type IV phospholipid pattern and unsaturated, di- and tetrahydrogenated menaquinones with nine isoprene units as the predominant isoprenologues [MK-9, MK-9(H_2), and MK-9(H_4)]. The tetrahydrogenation occurs at the sites of isoprene units III (the third unit from the 2-methyl–1, 4-naphthoquinone moiety) and VIII [MK-9(III, VIII-H_4)] (Ara and Kudo, 2007; Goodfellow et al., 1988; Goodfellow and Quintana, 2006; Kawamoto et al., 1981; Kroppenstedt, 1985, 1990a; Stackebrandt et al., 1994). This chemotaxonomic profile distinguishes members of the family *Streptosporangiaceae* from all of the other families classified in the order *Actinomycetales* including their nearest neighbors, the families *Nocardiopsaceae* and *Thermomonosporaceae*.

The presence of madurose in whole-organism hydrolysates is usually considered to be associated with actinomycetes that have a wall chemotype III, though this sugar has been detected in *Micromonospora rosaria* and several *Streptomyces* species (Nakagaito et al., 1993; Yokota et al., 1989). There is also an unconfirmed report of the presence of madurose in a wall chemotype I actinomycete with a streptomycete-like morphology (Weyland et al., 1982). In addition, 3-*O*-methylgalactosyl (madurosyl) units have been detected in the structure of teichoic acids of a *Nonomuraea roseoviolaceae* subsp. *carminata* strain (formerly *Actinomadura carminata*; Naumova et al., 1986).

Ecology. Members of the family *Streptosporangiaceae* are widely distributed in soil where they are presumably engaged in the turnover of organic matter. The introduction of innovative selective isolation procedures should provide an insight into the occurrence, distribution, numbers, and activities of members of the constituent genera, as exemplified by the multistage procedures introduced for the selective isolation of *Planobispora* and *Planomonospora* strains (Suzuki et al., 2001a, 2001b).

Enrichment and isolation procedures

Streptosporangiaceae strains are generally isolated by plating out suspensions of dry-heat treated, air-dried soil samples onto one or more selective synthetic media or by baiting environmental

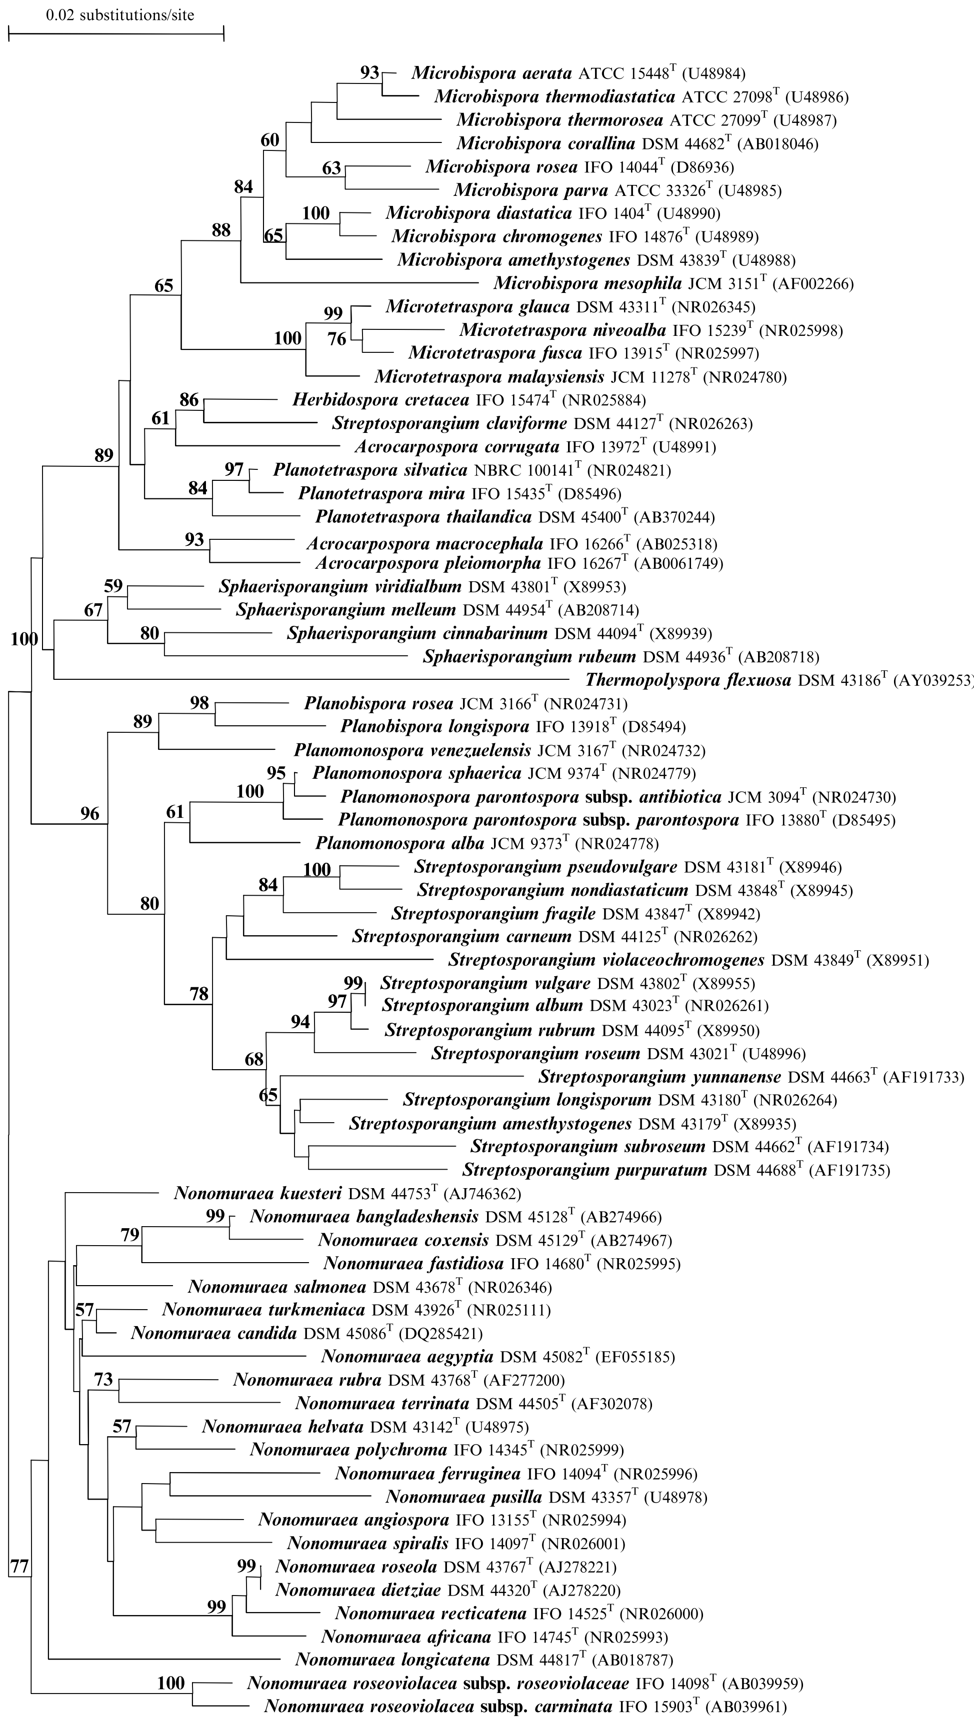

FIGURE 360. Neighbor-joining tree (Saitou and Nei, 1987) based on nearly complete 16S rRNA gene sequences (>1372 nucleotides) showing relationships between representatives of validly named species in the family *Streptosporangiaceae*. The numbers at the nodes indicate the level of bootstrap support (%) based on a neighbor-joining analysis of 1000 re-sampled datasets. ^{T}, Type strain.

samples with natural substrates. Various combinations of pretreatment regimes and selective media have been used to isolate members of the genera *Microbispora* and *Streptosporangium* (Nonomura and Ohara, 1960, 1969a, 1969b), *Microtetraspora* and *Nonomuraea* (Nonomura and Ohara, 1971c, 1971d), and *Nonomuraea* and *Streptosporangium* (Hayakawa and Nonomura, 1987a, 1987b; Nonomura, 1984).

Variations in the approaches mentioned above have involved treating heat-pretreated, air-dried soil suspensions with either benzethonium chloride or chloramine-T prior to plating onto HV agar and examining the incubated plates for the presence of *Streptosporangium* and related taxa (Hayakawa et al., 1991a, 1997). Similarly, *Microbispora* strains can be preferentially isolated by treating suspensions of heat-treated, air-dried soils with phenol, diluting with water, and plating onto HV agar supplemented with nalidixic acid (Nonomura and Hayakawa, 1988). *Microbispora*, *Planobispora*, *Planomonospora*, and *Streptosporangium* strains have been isolated by plating centrifuged supernatants of air-dried soils onto HV agar supplemented with streptomycin (Kizuka et al., 1997).

Members of the genera *Microbispora*, *Microtetraspora*, *Nonomuraea*, and *Streptosporangium* have been recovered from pretreated soil samples using a range of selective synthetic media supplemented with antibacterial antibiotics including ampicillin, bruneomycin, penicillin, polymixin B, rubromycin, and streptomycin (Hayakawa and Nonomura, 1987a, 1987b; Lavrova et al., 1972; Preobrazhenskaya et al., 1975b; Wang et al., 1999; Whitham et al., 1993). *Microtetraspora* and *Streptosporangium* strains have been isolated following irradiation of soil samples with microwaves, plating out soil suspensions onto Gauze agar 2 (Gauze et al., 1983) either without antibiotics or supplemented with levorin and nalidixic acid to suppress bacterial and fungal growth, respectively, and incubating at 28°C for up to six weeks (Bulina et al., 1997). Baiting environmental samples with pollen or hair has been used to good effect for the isolation of *Planobispora*, *Planomonospora*, and *Streptosporangium* strains (Couch, 1954, 1955a, 1963). Details of these and other traditional procedures recommended for the selective isolation of *Streptosporangiaceae* strains are given in the chapters dealing with the individual genera.

Taxonomic comments

The family *Streptosporangiaceae* was proposed by Goodfellow et al. (1990b) to provide a home for the genera *Microbispora*, *Microtetraspora*, *Planobispora*, *Planomonospora*, *Spirillospora*, and *Streptosporangium*. These genera had previously been assigned to higher taxa mainly based on what were seen at the time to be characteristic morphological traits. The family "*Actinosporangiaceae*", which was introduced to accommodate the genus *Streptosporangium* and "sporangiate" actinomycetes belonging to the genus *Actinoplanes* (Couch, 1955a), was subsequently renamed *Actinoplanaceae* (Couch, 1955b). In addition to *Actinoplanes*, the type genus, and *Streptosporangium*, this taxon included other actinomycetes considered to form "sporangia", namely the genera *Amorphosporangium*, *Ampullariella*, *Dactylosporangium*, *Kitasatoa*, *Pilimelia*, *Planobispora*, *Planomonospora*, and *Spirillospora* (Couch and Bland, 1974).

The original members of the family *Actinoplanaceae* were subsequently shown to belong to two distinct DNA–DNA relatedness groups. The genera *Actinoplanes*, *Ampullariella*, and *Dactylosporangium* were assigned to one group and the genera *Planobispora*, *Planomonospora*, and *Spirillospora* to the other one (Farina and Bradley, 1970). Organisms in the first group contained *meso*-and/or hydroxydiaminopimelic acid and glycine, i.e. they had a wall chemotype II *sensu* Lechevalier and Lechevalier (1970, 1970), whereas those in the second group contained *meso*-diaminopimelic acid and madurose (wall chemotype IIIB).

The realization that the genera *Actinoplanes* and *Dactylosporangium* had properties in common with the genera *Catellatospora*, *Couchioplanes*, *Catenuloplanes*, *Dactylosporangium*, *Micromonospora*, and *Pilimelia* led to these taxa being classified in the family *Micromonosporaceae* (Krasil'nikov 1938), a taxon which was emended first by Koch et al. (1996) and then by Stackebrandt et al. (1997). In the meantime, the genera *Amophosporangium* and *Ampullariella* were proposed as subjective synonyms of the genus *Actinoplanes* (Stackebrandt and Kroppenstedt, 1987). Subsequently, the genus *Kitasatoa* became a subjective synonym of the genus *Streptomyces* Goodfellow et al. 1986, and the genus *Spirillospora* became a member of the family *Thermomonosporaceae* (Stackebrandt et al. 1997) emend. Zhang et al. 2001.

Goodfellow and Cross (1984) assigned the oligosporic genera *Actinomadura*, *Excellospora*, *Microbispora*, *Microtetraspora*, and the "sporangiate" genera *Planobispora*, *Planomonospora*, *Spirillospora*, and *Streptosporangium* to what they considered to be a somewhat contrived aggregate group, the maduromycetes, a taxon that was recognized in the previous edition of *Bergey's Manual* (Goodfellow, 1989a, 1989b). However, with the exception of the genera *Actinomadura* and *Spirillospora*, these taxa were shown to form a coherent subgeneric group based on 16S rRNA gene cataloging and sequencing (Stackebrandt, 1986). The close relationships shown by the genera in this revised grouping were formalized by the proposal that *Streptosporangium* be recognized as the type genus of the new family *Streptosporangiaceae* Goodfellow et al. 1990b. In addition to the founder members, this family now includes the genera *Acrocarpospora*, *Herbidospora*, *Nonomuraea*, *Planotetraspora*, *Sphaerisporangium*, and *Thermopolyspora*. Some of these genera, notably *Nonomuraea*, *Sphaerisporangium*, and *Thermopolyspora* were based on or included taxa that had previously been misclassified with founder members of the family.

The genus *Nonomuraea* was proposed by Zhang et al. (1986a) to accommodate the *Actinomadura pusilla* group (Fischer et al., 1983; Meyer, 1989; Poschner et al., 1985) which had been assigned to the genus *Microtetraspora* (Kroppenstedt et al., 1990a) when it became apparent that the genus *Actinomadura* could be split into two distinct aggregate taxa (see corresponding section on the genus *Actinomadura*). In contrast, *Excellospora rubrobrunea* Agre and Guzeva 1975 was transferred to the revised genus *Actinomadura* as *Actinomadura rubrobrunea* (*ex* Krasil'nikov et al. 1968) Kroppenstedt et al. 1991. The genus *Thermopolyspora* was proposed to provide a taxonomic home for an organism that had initially borne the name "*Thermomonospora flexuosa*" Krasil'nikov and Agre 1964.

The genus *Streptosporangium* was shown to be markedly heterogeneous as it contained several species that had little in common either with one another or with the type species, *Streptosporangium roseum* (Kemmerling et al., 1993; Kudo et al., 1993; Ochi and Miyadoh, 1992). Stackebrandt et al. (1994) classified *Streptosporangium albidum* Furumai et al. 1968, *Streptosporangium viridogriseum* subsp. *kofuense* Okuda et al. 1966,

and *Streptosporangium viridogriseum* subsp. *viridogriseum* in a new genus, *Kutzneria*, as *Kutzneria albida*, *Kutzneria kofuensis*, and *Kutzneria viridogrisea*. Similarly, "*Streptosporangium cinnabarinum*" Celmer et al. 1977 and *Streptosporangium viridialbum* Nonomura and Ohara 1960 became initial members of the genus *Sphaerisporangium* as *Sphaerisporangium cinnabarinum* Ara and Kudo 2007 and *Sphaerisporangium viridialbum* (Nonomura and Ohara 1960) Ara and Kudo 2007.

Other changes in the composition of the genus *Streptosporangium* include the transfer of *Streptosporangium corrugatum* Williams and Sharples 1976 to the genus *Acrocarpospora* as *Acrocarpospora corrugata* (Williams and Sharples 1976) Tamura et al. 2000 and *Streptosporangium indianense* Gupta 1965 to the genus *Streptomyces* as *Streptomyces indianensis* (Gupta 1965) Kudo and Seino 1987. The type strains of *Herbidospora cretaceae* Kudo et al. 1993 and *Streptosporangium claviforme* Petrolini et al. 1992 have morphological features in common and belong to the same genomic species; these results led Kudo and his colleagues to propose that the *Streptosporangium claviforme* be seen as a subjective synonym of *Herbidospora cretacea*. However, the two strains form distinct, but related, phyletic lines in the 16S rRNA *Streptosporangiaceae* gene tree (Figure 360).

Differentiation of the genera of the family *Streptosporangiaceae*

The genera classified in the family *Streptosporangiaceae* can be delineated using genotypic and phenotypic markers. They are most readily separated by 16S rRNA gene sequence data including genus specific nucleotide signatures (Ara and Kudo, 2007; Goodfellow and Quintana, 2006), and by morphological criteria (Table 275). The genera *Acrocarpospora*, *Planobispora*, *Planomonospora*, *Planotetraspora*, *Sphaerisporangium*, and *Streptosporangium*, for instance, can be separated on the basis of the shape of spore vesicles, the number and shape of the enclosed spores, and by whether the latter are motile. Similarly, the oligosporic members of the family can be distinguished by the number of spores borne in chains on aerial hyphae and whether spores are formed on substrate hyphae. Microbisporae typically produce chains of two spores, microtetrasporae chains of four spores, whereas nonomuraea form either chains of spores or pseudovesicles. In all cases, the spores are formed on aerial hyphae. *Herbidospora* is unusual as it produces short chains of spores in clusters at the tips of sporophores that arise from substrate hyphae.

It is sometimes necessary to distinguish between genera classified in the family *Streptosporangiaceae* from morphologically similar taxa assigned to other families. Chemotaxonomic markers can be used to distinguish between *Microbispora*, *Microtetraspora* and *Nonomuraea* strains and members of the genus *Actinomadura* which also form chains of spores on aerial hyphae (Kroppenstedt et al., 1990a; Kudo et al., 1993). Actinomadurae typically contain MK-9(H_6), saturated at sites II, III, and VIII as the major isoprenologue, and diphosphatidylglycerol and phosphatidylinositol mannosides but lack nitrogenous phospholipids (phospholipid type I), whereas microbisporae, microtetrasporae, and nonomuraea have major amounts of MK-9(H_4), saturated at points III and VIII, and polar lipid patterns which contain diphosphatidylglycerol, hydroxyethanolamine, uncharacterized glycolipids, and glucosamine-containing phospholipids (phospholipid type IV) (Lechevalier et al., 1977, 1981).

Members of the family *Streptosporangiaceae* which form spore vesicles can be differentiated from morphologically similar strains belonging to the genera *Actinoplanes* and *Dactylosporangium* as the latter have a wall chemotype II and a phospholipid type I or II, whereas the former have a wall chemotype II and a phospholipid pattern IV (Goodfellow and Quintana, 2006; Koch et al., 1996; Vobis, 2006). Care also needs to be taken to distinguish between *Streptosporangium* and *Spirillospora* strains, though only the latter form motile spores (Vobis and Kothe, 1989). The vesicular hyphae within the spore vesicles of spirillosporae are branched, whereas those of streptosporangiae are not. Methods used to detect key chemical markers are cited in the section on the suborder *Streptosporangineae*.

Monciardini et al. (2002) designed a highly specific oligonucleotide primer set for the identification of *Streptosporangiaceae* strains. They also developed selective sets of oligonucleotide primers for PCR-amplification of rDNA for the recognition of members of the families *Micromonosporaceae*, *Streptomycetaceae*, and *Thermomonosporaceae*, and for *Dactylosporangium* strains. The application of these primer sets to environmental samples shows the presence of novel members of these taxa in soil samples.

Genus I. **Streptosporangium** Couch 1955a, 145[AL] emend. Stackebrandt, Kroppenstedt, Jahnke, Kemmering and Gürtler 1994, 268

Erika T. Quintana and Michael Goodfellow

Strep.to.spo.ran′gi.um. Gr. adj. *streptos* twisted; Gr. n. *spora* a seed; Gr. n. *angium* a vessel; N.L. neut. n. *Streptosporangium* spores coiled within a sporangium.

Aerobic, Gram-stain-positive, non-acid-fast actinomycetes which form a branched, stable, non-fragmenting mycelium bearing aerial hyphae that differentiate into globose or spherical spore vesicles. Oval, spherical, or rod-shaped, nonmotile sporangiospores are formed by septation of a single, coiled, unbranched hypha within the spore vesicle. Grows on a variety of organic and synthetic media. Biochemically versatile and chemically homogeneous. **Whole-organism hydrolysates contain *meso*-diaminopimelic acid and usually madurose. The peptidoglycan is of the A1γ type. Muramic acid moieties are *N*-acetylated. Cells contain major amounts of iso-, anteiso-, saturated, unsaturated, and 10-methyl-branched fatty acids, and MK-9(H_2) and MK-9(III, VIII-H_4) as the predominant isoprenologues. Mycolic acids are absent. Major phospholipids include diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, and glucosamine-containing phospholipids**. The phylogenetic position of the genus *Streptosporangium*, as determined by

16S rRNA gene sequence analysis, is in the family *Streptosporangiaceae*.

DNA G+C content (mol%): 69–71.

Type species: **Streptosporangium roseum** Couch 1955a, 151[AL].

Further descriptive information

Phylogeny. The genus *Streptosporangium* forms a distinct 16S rRNA gene clade within the evolutionary radiation encompassed by genera classified in the family *Streptosporangiaceae* (Ara and Kudo, 2007; Goodfellow et al., 1990b; Kudo, 2001). The genus encompasses 13 validly published species which are most closely related to the genera *Planobispora*, *Planomonospora*, and *Planotetraspora* (Figure 361). The two most distantly related species, *Streptosporangium violaceochromogenes* and *Streptosporangium yunnanense* share a 16S rRNA gene similarity of 95.2%. In contrast, the type strains of *Streptosporangium album*, *Streptosporangium roseum*, and *Streptosporangium vulgare* have identical 16S rRNA gene sequences.

Cell morphology. *Streptosporangium* strains characteristically form nonfragmenting, extensively branched substrate hyphae which carry aerial hyphae that differentiate into spore vesicles (Figure 362) which are borne either on short or long sporangiophores (Figure 363, Figure 364, and Figure 365). The spore vesicles may be carried singly or in clusters (Figure 364, Figure 365, and Figure 366). They may be globose or spherical and are usually 4–20 µm in diameter, but may be up to 40 µm. Spore vesicles originate as sac-like structures within which single, unbranched hyphae coil repeatedly and undergo septation giving rise to “sporangiospores” (Locci, 1976; Locci and Petrolini-Baldan, 1971). “Sporangiospores” are formed in the same way as the conidia of streptomycetes and not by cytoplasmic cleavage and nuclear division as in the formation of fungal sporangiospores (Lechevalier et al., 1966b; Sharples et al., 1974; Vobis and Kothe, 1985). Consequently, the use of the term sporangium is inappropriate in this context and should be replaced by the term spore vesicle (Cross, 1970; Sharples et al., 1974). However, unlike streptomycetes, the vesicular sheath does not usually persist around released spores.

As spore vesicles increase in size, the internal arrangement of hyphae and their septation into spores can be seen by the shape of the thin vesicular walls (Figure 364, Figure 365, and Figure 366), though the vesicular membrane of *Streptosporangium fragile* cannot be detected by light microscopy (Shearer et al., 1983). Nonmotile spores are released when spores vesicles are placed in water; the surrounding sheath is ruptured when the intersporal matrices swell and exert pressure on the vesicular membrane. The spores are spherical, oval, or rod shaped and have smooth walls. *Streptosporangium roseum* also forms streptomycete-like chains of arthrospores.

Chemotaxonomy. Streptosporangiae have a wall chemotype 111B (Lechevalier and Lechevalier, 1970a, 1970b), i.e. they contain *meso*-diaminopimelic acid in the wall peptidoglycan and madurose (3-*O*-methyl-D-galactose; Lechevalier and Gerber, 1970) in whole-organism hydrolysates. They have a peptidoglycan of the A1γ type (Schleifer and Kandler, 1972) and *N*-acetylated muramic acid (Kawamoto et al., 1981) and are rich in iso-, anteiso-, saturated, and unsaturated methyl-branched fatty acids (pattern 3c *sensu* Kroppenstedt, 1985; Kudo et al, 1993; Whitham et al., 1993; Stackebrandt et al., 1994; Zhang et al., 2002, 2005), but lack mycolic acids (Goodfellow and Minnikin, 1981; Kudo et al., 1993; Whitham et al., 1993).

Most *Streptosporangium* strains contain di- and tetrahydrogenated menaquinones with nine isoprene units as predominant

isoprenologues (Kroppenstedt, 1985; Kudo et al., 1993; Stackebrandt et al., 1994; Whitham et al., 1993), though *Streptosporangium purpuratum*, *Streptosporangium subroseum*, and *Streptosporangium yunnanense* also contain substantial proportions of unsaturated menaquinones with nine isoprene units (Zhang et al., 2002, 2005). Streptosporangiae typically have a phospholipid type IV (Lechevalier et al., 1977, 1981); they contain glucosamine-containing lipids with diphosphatidylglycerol, phosphatidylethanolamine, and phosphatidylinositol (Kudo

et al., 1993; Stackebrandt et al., 1994; Whitham et al., 1993). The presence of phosphatidylmethylethanolamine is variable (Zhang et al., 2005). *Streptosporangium subroseum* is unusual as it only contains phosphatidylethanolamine (Zhang et al., 2002) and hence has a wall chemotype II *sensu* Lechevalier et al. (1977, 1981). The G+C content of the DNA of streptosporangiae falls within the narrow range of 69.0–71 mol% (Farina and Bradley, 1970; Tsyganov et al., 1966; Yamaguichi, 1967; Zhang et al., 2002, 2005).

Colony morphology. *Streprosporangium* strains form well developed colonies on ISP media that are commonly used to cultivate filamentous actinomycetes (Shirling and Gottlieb, 1966). The substrate mycelium may be pink, red to dark brown, black, or deep purplish red, and the aerial mycelium pinkish-white or yellowish-pink, though the colors can vary between species and are influenced by the cultivation conditions. Some species produce colored diffusible pigments. *Streptosporangium amethystogenes* forms violet crystals of iodinin on oatmeal-YG medium (yeast extract 1 g, glucose 2 g, glycerol 2 g/l).

Nutrition and growth conditions. Streptosporangiae grow well on rich media such as arginine-vitamin agar (Nonomura and Ohara, 1969b, a), glucose-yeast extract agar (Waksman, 1950a), modified Bennett's agar (Jones, 1949), oatmeal agar (Shirling and Gottlieb, 1966), and yeast extract agar (Kudo et al., 1993). They grow particularly well and produce an abundant aerial spore mass on oatmeal-yeast extract (Nonomura and Ohara, 1960; Zhang et al., 2005). Some strains such as *Streptosporangium nondiastaticum* and *Streptosporangium pseudovulgare* require B-vitamins for growth (Zhang et al., 2005). It has also been shown that *Streptosporangium* strains do not have any particular preference for nutrient sources, either for the support of their growth or for their ability to produce anti-*Bacillus subtilis* substances (Platas et al., 1999). Streptosporangiae generally grow well at neutral pH and at 20–30°C; members of some species grow at 42°C (Nonomura, 1989a; Zhang et al., 2002, 2005).

Metabolism and genetics. Little is known about either the metabolism or genetics of *Streptosporangium* strains. In general, streptosporangiae use a broad range of compounds as sole carbon sources (Whitham et al., 1993; Zhang et al., 2002, 2005) and degrade diverse organic substrates (Whitham et al., 1993). *Streptosporangium pseudovulgare*, *Streptosporangium purpuratum*, and *Streptosporangium yunnanenis* degrade cellulose (Zhang et al., 2002, 2005). There is evidence that streptosporangiae can cleave diverse methylumbelliferone conjugated substrates (Whitham et al., 1993). Members of the genus have a chemoorganotrophic metabolism.

Streptosporangiae are a potentially rich source of novel commercially significant products, notably antibiotics (Donadio et al., 2002; Lazzarini et al., 2000), as exemplified by the production of lipopeptides from *Streptosporangium amethystogenes* (Takizawa et al., 1995); glycopeptides from *Streptosporangium carneum* (Michel and Yao, 1991); selenomycin from "*Streptosporangium brasiliense*" (Coronelli and Thiemann, 1969); anthracyclines from *Streptosporangium fragile* (Nash et al., 1981; Shearer et al., 1983); sporamycin from "*Streptosporangium koreanum*" (Celmer et al., 1978); oligopeptides from *Streptosporangium nondiastaticum* (Shokichi et al., 1988); a novel protein (Umezawa and Kamiyama, 1983) and sporamycin from *Streptosporangium pseudovulgare* (Umezawa et al., 1976); an ansa-macrolactam (Hacene et al., 1998), sporangirosomycin (Ghazal and Alb-El-Aziz, 1993), and thiosporamycin (Celmer et al., 1978) from *Streptosporangium roseum*; sibiromycin from "*Streptosporangium sibiricum*" (Brazhnikova et al., 1972; Gauze et al., 1969); platomycins A and B (Takasawa et al., 1975) and victomycin from *Streptosporangium violaceochromogenes* (Kawamoto et al., 1975); and sporacuracins A and B from *Streptosporangium vulgare* (Atsushi et al., 1975).

A new calmodulin antagonist, genistein, has been isolated from *Streptosporangium vulgare* (Goto et al., 1987), a hematopoietic inducer from *Streptosporangium amethystogenes* subsp. *fukuiensis* (Donadio et al., 2002), and endothelin converting enzyme inhibitors from *Streptosporangium roseum* (Tsurumi et al., 1994, 1995). In addition, virginiamycin type peptolides have been isolated from "*Streptosporangium cinnabarinum*" and "*Streptosporangium koreanum*" (Celmer et al., 1977), 1,6- dihydroxy-2-chlorophenazine, a novel phenazine antifungal antibiotic from a *Streptosporangium* strain (Patel et al., 1984), 1-hydroxy-4-methoxy-2-naphthoic acid, a herbicidal compound, from "*Streptosporangium cinnabarinum*" (Pfefferle et al., 1997), a thermostable glucoamylase from a streptosporangial endophyte of maize leaves (Stamford et al., 2002), and pigment-like antibiotics from a *Streptosporangium* strain isolated from an Algerian soil (Boudjella et al., 2007). Other potentially useful substances include inhibitors of lactic acid production by oral flora (Ikeda et al., 1993) and insecticidal compounds (Mishra et al., 1987).

Pfefferle et al. (2000) highlighted the importance of fermentation conditions in the production of secondary metabolites from streptosporangiae. They showed that the optimal conditions for secondary metabolite production were completely different from those of streptomycetes and identified oxygen tension as an important parameter for the optimal production of secondary metabolites from streptosporangiae in submerged culture.

Antibiotic sensitivity. The antibiotic sensitivity profiles of individual species, where known, are given in the species descriptions.

Pathogenicity. There are no proven grounds for believing that streptosporangiae have a role as clinical or veterinary pathogens, though "*Streptosporangium bovinum*" was isolated from infected bovine hooves (Batista et al., 1963).

Ecology. Streptosporangiae have been isolated infrequently from diverse sources, including coastal sediments (Bredholdt et al., 2007), cow dung (Garg et al., 2003), earthworm casts (Mba, 1997), forest soils (Potekhina, 1965; Xu et al. (1996), leaf litter (Van Brummelen and Bent, 1957), plant roots (Coombs and Franco, 2003; de Araujo et al., 2000; Sardi et al., 1992; Solans and Vobis, 2003), and lake sediments (Johnston and Cross, 1976; Lee and Hwang, 2002; Willoughby, 1969a), though organisms labeled *Streptosporangium* type 1 from freshwater streams (Willoughby, 1969b) probably belong to the genus *Actinoplanes*, given their morphological features and ability to form motile spores.

The introduction of an innovative selective isolation procedure showed that streptosporangiae are an integral part of actinomycete communities in soils (Nonomura and Ohara,

1969a) where they presumably have a role in the turnover of organic matter. The number of *Streptosporangium* strains in Japanese soils was estimated at 10^4–10^6 colony forming units per gram dry weight soil (Nonomura, 1984; Nonomura and Ohara, 1969a); lower numbers have been reported from pasture and woodland soils (Whitham et al., 1993). There is evidence that slightly acid, humus rich soils are a good source of streptosporangiae (Hayakawa et al., 1988; Lee and Hwang, 2002; Nonomura and Hayakawa, 1988; Seong et al., 2001).

The application of new selective isolation procedures designed for the recovery of rare actinomycetes have shown that streptosporangiae are present in a range of soil types including chernozem soils (Li et al., 2002), corn and paddy field soils (Nonomura and Hayakawa, 1988) (Masayuki et al., 1991), peaty soils (Zenova et al., 2008), steppe chestnut and desert pale brown soils (Norovsuren et al., 2007; Zhadambaa et al., 2007), and a Saharan soil (Boudjella et al., 2006).

Enrichment and isolation procedures

Isolation and enumeration of streptosporangiae and related actinomycetes, notably microbisporae and microtetrasporae, can be achieved by dry-heat treatment of air-dried soil samples and dilution plate culture with selective synthetic media (Hayakawa and Nonomura, 1984, 1987a, 1987b, 1989; Nonomura and Hayakawa, 1988; Nonomura and Ohara, 1969a, 1969b; Nonomura and Ohara, 1971a, 1971c, 1971d). To this end, soil samples are dried slowly at room temperature for 7 d, passed through a 2 mm sieve, gently ground in a mortar, spread on filter paper, and heated in a hot air oven at 100–120°C for an hour. This procedure greatly reduces the numbers of bacteria and streptomycetes, but leads to an increased isolation frequency of streptosporangiae. There is evidence that pretreatment of soil suspensions with sodium dodecyl sulfate (0.05%, w/v) and yeast extract (6%, w/v) at 40°C for 20 min, followed by dilution in water, activates spores of actinomycetes but kills vegetative cells of other bacteria, thereby leading to increased counts of streptosporangiae and related organisms on isolation plates.

Suspensions of pretreated soil are used to inoculate one or more of the selective synthetic media. Arginine-vitamins (AV) agar*, chitin – V agar†, humic-vitamin (HV)‡, and C-1§ and C-2** have been recommended for the selective isolation of streptosporangiae and related actinomycetes (Hayakawa and Nonomura, 1987a, 1987b; Nonomura and Ohara, 1969a). These media are supplemented with antifungal antibiotics and sometimes with penicillin and polymixin B (Whitham et al., 1993). Inoculated plates are incubated at 30°C for 4–6 weeks and colonies examined for the presence of spore vesicles by using a light microscope fitted with a long working distance objective. The highest counts and cleanest plates are usually obtained with HV-vitamin agar. Growth of streptosporangiae around soil particles can be observed when pretreated soil particles (0.5 g) are sprinkled over selective media that have been incubated for 1 month at 30°C.

Hayakawa et al. (1991a) recommended an improved method for the selective isolation of streptosporangiae from soil. This procedure was based on the ability of streptosporangial spores to withstand dry heat at 120°C for an hour and treatment with benzylthonium chloride (BC), as well as the capacity of streptosporangiae to grow in the presence of leukomycin and nalidixic acid. The dry heat and BC treatments greatly reduce the numbers of bacteria and unwanted actinomycetes, including streptomycetes, from isolation plates. In turn, nalidixic acid in HV agar suppresses the growth of BC-resistant bacteria while leukomycin increases the selectivity of HV agar for streptosporangiae by eliminating unwanted bacteria that remain after the employment of the various pretreatments. In general, streptosporangiae account for about 20% of colonies growing on the resulting isolation plates.

The improved procedure involves several steps. Initially, an air-dried soil sample is ground in a mortar and heated at 120°C for an hour prior to the preparation of a 10^{-1} dilution in water. Half a ml of the 10^{-1} preparation is added to 4.5 ml of sterile 5 mm phosphate buffer (pH 7.0) containing BC at a final concentration of 0.01%, w/v. This preparation is kept at 30°C for 30 min with occasional stirring and a 1 ml fraction diluted in sterile tap water (1:10 or 1:15). Aliquots (0.1 or 0.2 ml) of this preparation are spread over the surfaces of HV agar supplemented with leukomycin in ethanol (1 mg/l) and nalidixic acid (20 mg/l). The inoculated plates are incubated at 30°C for 3–4 weeks then examined as before.

Other procedures based on pretreatment of air-dried soil samples and plating onto selective media have been used to isolate members of genera classified in the family *Streptosporangiaceae*, notably *Herbidospora*, *Microbispora*, *Microtetraspora*, and *Streptosporangium*. Hayakawa et al. (1997) found that spores from representatives of these taxa, unlike those from *Micromonospora*, *Nocardia*, and *Streptomyces* strains, were resistant to toluene-*p*-sulfon sodiumchloroamide trihydrate (chloramine-T). Water suspensions of air-dried soil treated with chloramine-T (1%) and plated onto HV agar supported the growth of the target organisms after incubation at 30°C for 3 weeks. The chlorination treatment specifically inhibits the growth of nonfilamentous bacteria and unwanted actinomycetes, thereby facilitating the isolation of the target genera. Isolates presumptively assigned to the genus *Streptosporangium*, on the basis of

*AV agar (Nonomura and Ohara, 1969a): arginine, 0.3 g; glucose, 1 g; glycerol, 1 g, K_2HPO_4, 0.3 g; $MgSO_4 \cdot 7H_2O$, 0.2 g; NaCl, 0.3 g; agar, 15 g; distilled water, 1000 ml; B vitamins (thiamin HCl, riboflavin, niacin, pyridoxine HCl, isositol, calcium pantothenate, *p*-aminobenzoic acid, each at 0.5 mg; biotin, 0.25 mg); trace salts ($CuSO_4 \cdot 5H_2O$, 1 mg; $Fe_2(SO_4)_3$, 10 mg; $MnSO_4 \cdot 7H_2O$, 1 mg; $ZnSO_4 \cdot 7H_2O$, 1 mg); antibiotics (actidione, 50 mg; nystatin, 5 mg; penicillin G, none or 0.8 mg; polymixin B, none or 4 mg); pH 6.4.

†Chitin-V agar (Hayakawa and Nonomura, 1984): colloidal chitin, 2 g (dry w.); K_2HPO_4, 0.15 g; $MgSO_4 \cdot 7H_2O$, 0.2 g; NaCl, 0.3 g; $CaCO_3$, 0.02 g; $FeSO_4 \cdot 7H_2O$, 10 mg; $ZnSO_4 \cdot 7H_2O$, 1 mg; $MnCl_2$, 1 mg; agar, 18 g; distilled water, 1000 ml; B vitamins, as for AV agar; actidione, 50 mg; pH 7.2.

‡HV vitamin agar (Hayakawa and Nonomura, 1984; Nonomura, 1984): humic acid, 1 g (used as an alkaline solution; artificial humic acid prepared from glucose and urea may be used, as may natural humic acids from soil humus, but the pale brown humic acid designated as Rp type gives the best results); Na_2HPO_4, 0.5 g; $MgSO_4 \cdot 7H_2O$, 0.05 mg; KCl, 1.7 g; $FeSO_4 \cdot 7H_2O$, 0.01 g; $CaCO_3$, 0.02 g; agar, 18 g; distilled water, 1000 ml; B vitamins, as for AV agar; actidione, 50 mg; pH 7.2.

§C-1 medium (Nonomura and Ohara, 1969b): casamino acids, 2 g; K_2HPO_4, 0.3 g; $MgSO_4 \cdot 7H_2O$, 0.5 g; NaCl, 0.3 g; agar, 20 g; distilled water, 1000 ml; trace salts ($FeSO_4 \cdot 7H_2O$, 10 mg; $MnSO_4 \cdot 7H_2O$, 1 mg; $CuSO_4 \cdot 5H_2O$, 1 mg); B vitamins (thiamine HCl, riboflavin, niacin, pyridoxine HCl, inositol, calcium pantothenate, *p*-aminobenzoic acid, each 0.5 mg; biotin 0.25 mg); pH 7.2.

**C-2 medium (Nonomura and Ohara, 1969b): casamino acids, 0.5 g; and asparagine, 0.5 g, instead of casamino acids, 2 g, in the composition of C-1 medium. The other components are the same as for C-1 medium.

their ability to form spore vesicles, accounted for 1.8–4.1 × 10^5 c.f.u./g dry weight soil.

Pretreatment of soil suspensions with extreme high frequency (EHF) radiation prior to plating onto Gauze's agar 2 supplemented with nalidixic acid (10 μg/ml) and either levorin (20 μg/ml) or nystatin (50 μg/ml) and incubation at 28°C for 2–6 weeks led to the isolation of increased numbers of rare actinomycetes from soil including streptosporangiae (Bulina et al., 1997; Li et al., 2002). It seems likely that EHF radiation inhibits the growth of unicellular bacteria and breaks the dormancy of actinomycete spores. Streptosporangiae have also been isolated by plating out surface sterilized root material onto selective media (Cao et al., 2005; de Araujo et al., 2000).

An indirect immunomagnetic capture (IMC) method was developed by Mullins et al. (1995) for the selective recovery of *Streptosporangium fragile* from sterile and non-sterile soil. IMC recovery rates for *Streptosporangium fragile* spores from soil were usually in the range of 10–20% of the counts obtained by traditional plating. However, the capture method resulted in cleaner isolation plates and hence could be expected to enhance the successful isolation of the target organism compared with traditional plating methods.

Maintenance procedures

The most convenient method for short-term storage is by serial transfer from agar slants of appropriate media, such as oatmeal-yeast extract agar (Nonomura and Ohara, 1960), every 2 months. The tubes should be tightly closed with cotton plugs dipped in melted paraffin wax and stored at 4°C and room temperature. Longer term preservation of strains can be achieved as frozen stocks in 20% (v/v) aqueous glycerol at −80°C (mechanical freezer) to −172°C (liquid nitrogen vapor) or by using established lyophilization procedures. Strains can also be kept as mycelial suspensions in 20% aqueous glycerol at −20°C to −72°C.

Procedures for testing special characters

Iodinin production is detected after culturing on oatmeal agar supplemented with 0.1% (w/v) yeast extract for 1 month at 23–30°C. Utilization of carbon sources is determined by comparing growth on a given carbon source in basal C-1 or C-2 media with two controls, growth on the basal medium alone, and growth on the basal medium plus 0.5% (w/v) glucose. Most species of *Streptosporangium* do not grow on ISP Carbon Utilization Medium (Shirling and Gottlieb, 1966). Other useful physiological tests are hydrolysis of starch agar supplemented with yeast extract (0.5 g/l), nitrate reduction to nitrite in Bacto-nitrate broth (Difco) supplemented with yeast extract (2 g/l), and gelatin liquefaction (gelatin, 200 g; peptone, 5 g; yeast extract, 2 g; glucose, 2 g; distilled water, 1000 ml).

Differentiation of the genus *Streptosporangium* from other genera

The genus *Streptosporangium* is phylogenetically distinct from all other genera which contain organisms that produce spore vesicles. At present, morphology is the sole criterion used to distinguish between genera classified in the family *Streptosporangiaceae* (see Table 276 in the section on the family). *Streptosporangium* can be readily distinguished from the genera *Herbidospora*, *Microtetraspora*, *Microbispora*, and *Nonomuraea* by its ability to form spore vesicles and from the remaining genera by the shape of spore vesicles, the number of spores they contain, and whether or not the latter are motile. It can be difficult to distinguish between *Streptosporangium fragile*, which has a very thin vesicular membrane, and *Nonomuraea* strains which produce pseudovesicles covered by a slimy material. Similarly, the genus *Spirillospora* may be confused with species of the genus *Streptosporangium* (Vobis and Kothe, 1989). All of the strains belonging to these taxa have multispored, usually spherical, spore vesicles. However, these taxa can be distinguished on the basis of their polar lipid patterns and by the ability of spirillosporae to form motile spores.

Taxonomic comments

Couch (1955a) proposed the genus *Streptosporangium* for sporangiate actinomycetes that formed nonmotile sporangiosphores on an abundant aerial mycelium. Initially, only one species, *Streptosporangium roseum*, was recognized. Additional species were added to the genus primarily based on the capacity of strains to form spore vesicles, as exemplified by proposals for *Streptosporangium album* Nonomura and Ohara 1960, *Streptosporangium amethystogenes* Nonomura and Ohara 1960, *Streptosporangium longisporum* Schäfer 1969, *Streptosporangium nondiastaticum* Nonomura and Ohara 1969b, and *Streptosporangium viridialbum* Nonomura and Ohara 1969b. More exacting studies showed the genus to be heterogeneous, notably on the basis of spore and spore vesicular morphology detected by scanning electron microscopy (Nonomura, 1989a), electrophoretic mobility of ribosomal protein AT-L30 (Ochi and Miyadoh, 1992), partial amino acid sequencing of the N termini of AT-L30 proteins (Ochi et al., 1993), 5S and 16S rRNA gene sequences (Kemmerling et al., 1993; Kudo et al., 1993), and on the discontinuous distribution of chemotaxonomic markers (Stackebrandt et al., 1994).

Stackebrandt and his colleagues assigned members of the genus to two groups based on the discontinuous distribution of chemical markers. Most species, including *Streptosporangium roseum*, the type species, had a phospholipid type IV and predominant menaquinones of the MK-9(H_2) and MK-9(III, VIII-H_4), MK-9 and/or MK-9(H_6) type. The second group, which encompassed *Streptosporangium albidum* and the two subspecies of *Streptosporangium viridugriseum*, had a phospholipid type II and MK-9(II, III, H_4) as the predominant isoprenologues. These results were in excellent agreement with corresponding 16S rRNA gene sequencing data. Consequently, Stackebrandt and his co-workers proposed that *Streptosporangium albidum* Furumai et al. 1968, *Streptosporangium viridogriseum* subsp. *viridogriseum* Nonomura and Ohara 1969b, and *Streptosporangium viridogriseus* subsp. *kofuense* Okuda et al. (1966) be assigned to a new taxon, the genus *Kutzneria*, as *Kutzneria albida* comb. nov., *Kutzneria viridogrisea* comb. nov., and *Kutzneria kofuensis*, respectively, results supported by numerical phenetic data (Whitham et al., 1993).

The position of "*Streptosporangium cinnabarinum*" JCM 3291 and *Streptosporangium viridialbum* DSM 43801^T in the genus

[b]Data taken from Nonomura (1989a), Mertz and Yao (1990), Goodfellow (1992), Kudo (2001), Whitham et al. (1993), and Zhang (2002, 2005).

Streptosporangium was questioned by several workers, especially on the basis of 16S rRNA gene sequence data (Stackebrandt et al., 1994; Tamura et al., 2000; Ward-Rainey et al., 1996). These organisms were subsequently found to share genotypic and phenotypic features in common with five soil isolates that were assigned to the new genus *Sphaersporangium* as *Sphaersporangium melleum* and *Sphaersporangium rubeum* (Ara and Kudo, 2007). They also found that "*Streptosporangium cinnabarinum*" and *Streptosporangium viridialbum* could be distinguished from one another and from the other two taxa based on DNA–DNA relatedness and phenotypic data. Consequently, they transferred "*Streptosporangium cinnabarinum*" Celmer et al. 1977 and *Streptosporangium viridialbum* (Nonomura and Ohara 1960) to the genus *Sphaerosporangium* as *Sphaerosporangium cinnabarinum* sp. nov. and *Sphaerosporangium viridialbum* comb. nov., respectively. The genus name *Sphaerosporangium* (*sic*) was corrected on validation [Rule 61 of the *Bacteriological Code* (1990 Revision)] to *Sphaerisporangium* (Lists Editor IJSEM, 2007).

Several other species have been shown to be misplaced in the genus *Streptosporangium*. The type strain of *Streptosporangium claviforme* Petrolini et al. 1992 and *Herbidospora cretacea* Kudo et al. 1993 belong to the same genomic species and form a distinct 16S rRNA gene clade in the *Streptosporangiaceae* gene tree (Tamura et al., 2000), as can be seen in Figure 361 (see section on the family *Streptosporangiaceae*). *Streptosporangium corrugatum* Williams and Sharples 1976 was found to have properties consistent with its transfer to the genus *Acrocarpospora* as *Acrocarpospora corrugata* (Williams and Sharples 1976) Tamura et al. 2000. The proposal to transfer *Streptosporangium indianense* Gupta 1965 to the genus *Streptomyces* as *Streptomyces indianensis* (Gupta 1965) Kudo and Seino 1987 is underpinned by a wealth of phenotypic data, notably by the formation of spiral spore chains and the absence of spore vesicles (Whitham et al., 1993). "*Streptosporangium album* subsp. *thermophilum*" Manachini et al. 1965 is a thermophile, but has been shown to be a member of the genus *Thermoactinomyces* (Goodfellow and Cross, 1984).

The changes outlined above leave the genus *Streptosporangium* as a well-defined taxon that encompasses 13 validly published species. DNA–DNA relatedness studies support the taxonomic integrity of several *Streptosporangium* species (Zhang et al., 2002, 2005) though they do suggest that the two *Streptosporangium amethystogenes* subspecies represent distinct genomic species (Iinuma et al., 1996b), a result underpinned by phenotypic data (Table 276). Further comparative studies are also needed to establish relationships between *Streptosporangium album*, *Streptosporangium roseum*, and *Streptosporangium vulgare* as the type strains of these taxa have identical 16S rRNA gene sequences and share morphological properties. These organisms also have similar polar lipid patterns but can be separated using quantitative fatty acid and menaquinone data (Mertz and Yao, 1990; Stackebrandt et al., 1994). However, there is evidence that the genus is underspeciated (Wang et al., 1999; Whitham et al., 1993). Indeed, Whitham and his colleagues found that isolates from seven environmental samples presumptively assigned to the genus formed 23 centers of variation based on the numerical taxonomic data.

Strains described as "*Streptosporangium brasiliense*" (Coronelli and Thiemann, 1969), "*Streptosporangium koreanum*" (Celmer et al., 1977), and "*Streptosporangium rubrum*" (Potekhina, 1965), share very high 16S rRNA gene similarities with one another and with the type strains of *Streptosporangium album*, *Streptosporangium roseum*, and *Streptosporangium vulgare* (Tamura et al., 2000). Fatty acid date indicate that "*Streptosporangium brasiliense*" and "*Streptosporangium koreanum*" strains are closely related to one another and to the type strain of *Streptosporangium roseum*, whereas a strain labeled "*Streptosporangium sibiricum*" (Potekhina, 1965) formed a distinct single membered group when fatty acid data were expressed as Euclidian distances (Mertz and Yao, 1990). Further comparative studies are needed to determine the relationships between these invalidly named taxa and representatives of validly named *Streptosporangium* species.

Differentiation of species of the genus *Streptosporangium*

Streptosporangium species can be distinguished by using a combination of phenotypic features (Table 276), although a common set of tests has not been used in the description of all species. Most of the type strains can be distinguished on the basis of their 16S rRNA gene sequences, as seen in Figure 361. There is also evidence that these organisms can be differentiated on the basis of their sugar and polar lipid patterns and by qualitative and quantitative differences in fatty acid and menaquinone composition (Kroppenstedt, 1985; Stackebrandt et al., 1994; Whitham et al., 1993; Zhang et al., 2002), though results from individual studies on the same organism do vary, possibly reflecting differences in growth conditions and experimental protocols.

Improved phenotypic tests are needed for the identification of streptosporangiae to the species level. Whitham (1988) generated a probability matrix based on 26 phenotypic properties for the computer-assisted identification of streptosporangiae to established and putatively novel *Streptosporangium* species. Kim (1993), in a continuation of this work, was able to identify known and putatively novel streptosporangiae, notably ones isolated from a range of soil samples.

List of species of the genus *Streptosporangium*

1. **Streptosporangium roseum** Couch 1955a, 151[AL] ("*Angiococcus moliroseus*" Petersen 1959, 169)

ro′se.um. L. neut. adj. *roseum* rose-colored.

Aerial mycelium is pink and the substrate mycelium yellowish brown to orange on oatmeal-yeast extract agar; soluble pigment is reddish to purplish brown on this medium. Spore vesicles are usually 8–10 µm in diameter but larger ones, up to 20 µm, are found in some strains. Spores spherical, short or bent rods, 1.8–2 µm in diameter. Hydrolyzes esculin, but not urea. Nitrate is reduced.

Degrades arbutin, elastin, RNA, and L-tyrosine, but not guanine, hypoxanthine, keratin, testosterone, Tween 20, or xanthine.

Dextrin, inulin, mannose, sucrose, trehalose, and xylose are used as sole carbon sources, but dextran, fructose, lactose, melezitose, melibiose, raffinose, sorbitol, sorbose, stachyose, starch, and xylitol (all at 1%, w/v) are not. Does not use acetate, butyrate, citrate, hippurate, malonate, or pyruvate as sole carbon sources (all at 0.1%, w/v).

Grows in the presence of crystal violet (0.001%, w/v), phenol (0.01%, w/v), phenyl ethanol (0.2%, v/v), potassium tellurite (0.01%, w/v), sodium chloride (2%, w/v), and thallous acetate (0.001%, w/v), but is sensitive to crystal violet (0.01%, w/v), phenol (0.01%, w/v), phenyl ethanol (0.3%, v/v), sodium azide (0.001%, w/v), and sodium chloride (4%, w/v).

Resistant (μg/ml) to amoxycillin (500), azlocillin (500), bactracin (50), cefoxitin (250), cephaloridine (250), cephadrine (500), chloramphenol (25), clavulanic acid (50), flucloxicillin (50), fusidic acid (0.5), keflin (250), kufzol (500), lincomycin (5), mecillinam (500), methicillin (500), oleandomycin phosphate (250), penicillin G (50), pseudomonic acid (500), sulfomethoxazole (25), ticarcillin (50), and tyrothricin (5), but is sensitive to bacitracin (50), clavulanic acid (500), flucloxicillin (250), fusidic acid (0.5), lincomyciin (25), penicillin G (250), rifampin (0.5), tetracycline (5), ticarcillin (500), and vancomycin hydrochloride (5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain galactose and madurose. The fatty profile includes $C_{14:0}$ iso (8.9%), $C_{15:0}$ (2.9%), $C_{16:0}$ iso (43.3%), $C_{16:0}$ (3.7%), $C_{16:0}$ 10-methyl (2.6%), $C_{17:0}$ anteiso (3.1%), $C_{17:0}$ (3.9%), $C_{17:0}$ 10-methyl (18.7%), and $C_{18:0}$ (3.0%). The cellular polar lipid pattern includes diphosphatidylglycerol, hydroxyphosphatidylethanolamine, phosphatidylethanolamine, phosphatidylinositol, and ninhydrin-positive and sugar-positive phospholipids.

Source: a vegetable garden soil.

DNA G+C content (mol%): 70 (HPLC).

Type strain: ATCC 12428, CBS 313.56, DSM 43021, NBRC 3776, JCM 3005, NCIB 10171, NRRL B-2505, VKM Ac-807.

Sequence accession no. (16S rRNA gene): U48996, X70425, X89947.

2. **Streptosporangium album** Nonomura and Ohara 1960, 407[AL]

al′bum. L. neut. adj. *album* white.

Aerial mycelium is white and the substrate mycelium pale yellow on oatmeal-yeast extract agar, but does not form a diffusible pigment on this medium. Melanin pigments are not produced. Spore vesicles are 6–8 μm in diameter and sporangiospores are 1.0–1.3 × 1.5–1.9 μm. Esculin is hydrolyzed, but hippurate and urea are not. Arbutin, L-tyrosine, and Tween 80 are degraded, but guanine, hypoxanthine, keratin, pectin, testosterone, and xanthine are not. Adonitol, dextrin, fructose, inulin, maltose, mannose, raffinose, stachyose, sucrose, turanose, and xylose are used as sole carbon sources, but lactose, melezitose, melibiose, sorbitol, starch, or xylitol (all at 1%, w/v) are not. Acetate and butyrate are used as sole carbon sources, but citrate, hippurate, malonate, propionate, or pyruvate (all at 0.1%, w/v) are not.

Grows in the presence of potassium tellurite (0.005%, w/v), sodium chloride (1%, w/v), and thallous acetate (0.005%, w/v), but is sensitive to crystal violet (0.0005%, w/v), phenol (0.005%, w/v), phenyl ethanol (0.1%, v/v), potassium tellurite (0.01%, w/v), sodium azide (0.005%, v/v), sodium chloride (2%, w/v), and thallous acetate (0.001%, w/v).

Resistant (μg/ml) to amoxycillin (50), cefoxitin (25), cephaloridine (5), chloramphenol (5), clavulanic acid (250), fusidic acid (5), kefzol (50), lincomycin (25), mecillinam (50), neomycin sulfate (0.5), oleandomycin phosphate (5), penicillin G (5), sulfomethoxazole (25), tetracycline (0.5), ticarcillin (50), and tyrothricin (5), but is sensitive to amoxycillin (500), azlocillin (25), bacitracin (25), cefoxitin (50), cephaloridine (25), cephradine (25), chloramphenicol (25), clavulanic acid (500), flucloxicillin (50), fusidic acid (25) gentamicin sulfate (5), keflin (25), kefzol (250), lincomycin (50), mecillinam (250), methicillin (250), neomycin sulfate (5), oleandomycin phosphate (25), penicillin G (25), pseudomonic acid (500), rifampin (0.5), streptomycin sulfate (5), tetracycline (5), and ticarcillin (250).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain galactose and a trace of madurose. The fatty profile includes $C_{12:0}$ (8.1%), $C_{14:0}$ iso (4.3%), $C_{15:0}$ (7.3%), $C_{16:0}$ iso (43.3%), $C_{16:0}$ iso (8.0%), $C_{16:1}$ (3.9%), $C_{16:0}$ (6.8%), $C_{16:0}$ 10-methyl (2.6%), $C_{17:0}$ anteiso (21.6%), $C_{17:0}$ (5.3%), $C_{17:0}$ 10-methyl (25.7%), $C_{18:1}$ *cis* (2.8%), and $C_{18:0}$ 10-methyl (3.7%). The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol mannosides, phosphatidylmethylethanolamine, and several uncharacterized components. The predominant menaquinones are MK-9(H_2) (55.7%) and MK-9(H_4) (42.9%); also contains minor amounts of MK-9(H_0) (1.4%).

Source: a soil sample collected in Japan.

DNA G+C content (mol%): not determined.

Type strain: CBS 429.61, DSM 43023, NRBC 13900, JCM 3025, KCC A-0025, NRRL B-2635, VKM Ac-636.

Sequence accession no. (16S rRNA gene): D85469, X89934.

3. **Streptosporangium amethystogenes** Nonomura and Ohara 1960, 407[AL]

am.e.thys.to′ge.nes. L. adj. *amethystinus* amethyst colored; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *amethystogenes* producing violet-colored (crystals).

Aerial mycelium is pink and the substrate mycelium pale brownish gray. Does not produce melanin pigments. Spore vesicles are 6–8 μm in diameter and sporangiospores are 1.0–1.3 × 1.5–1.9 μm.

Esculin is hydrolyzed, but hippurate is not. Degrades arbutin, DNA, elastin, RNA, and L-tyrosine, but not guanine, hypoxanthine, keratin, testosterone, or xanthine. Mannose, trehalose, and xylose are used as sole carbon sources, but dextran, lactose, melezitose, melibiose, raffinose, sorbitol, sorbose, stachyose, starch, and xylitol (all at 1%, w/v) are not. Does not use acetate, butyrate, citrate, hippurate, malonate, propionate, or pyruvate as sole carbon sources (all at 0.1%, w/v).

Grows in the presence of crystal violet (0.0005%, w/v), phenol (0.01%, w/v), phenyl ethanol (0.01%, v/v), potassium tellurite (0.001%, w/v), sodium chloride (1.0%, w/v), and thallous acetate (0.0005%, w/v), but is sensitive to crystal violet (0.01%, w/v), phenol (0.01%, w/v), potassium tellurite (0.01%, v/v), sodium azide (0. 01%, w/v), and sodium chloride (4%, w/v).

Resistant (μg/ml) to gentamicin sulfate (5), sulfomethoxazole (3), tetracycline (0.5), and vancomycin hydrochloride (0.5), but is sensitive to amoxycillin (25), azlocillin (25), bacitracin (25), cefoxitin (25), cephaloridine (50), cephradine (25), chloramphenicol (5), clavulanic acid (25), flucloxicillin (50), fusidic acid (0.5), gentamicin sulfate (25), keflin (25), kefzol (25), lincomycin (25), mecillinam (50), methicillin (250), neomycin sulfate (5), oleandomycin phosphate (25), penicillin G (25), pseudomonic acid (500), rifampin (5), streptomycin sulfate (5), tetracycline (5), ticarcillin (50), tyrothrecin (5), and vancomycin hydrochloride (5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain madurose. The fatty acid profile includes $C_{16:0}$ iso (7.9%), $C_{16:0}$ (13.9%), $C_{17:0}$ anteiso (10.7%), $C_{17:0}$ (4.2%), $C_{18:1}$ *cis* (13.2%), $C_{18:1}$ *trans* (45.1%), and $C_{18:0}$ (3.4%). The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. The predominant menaquinones are MK-9(H_2) (49.4%) and MK-9(III, VIII-H_4) (33.5%); also contains MK-9(H_0) (10.1%).

Source: a soil sample collected in Japan.

DNA G+C content (mol%): not determined.

Type strain: ATCC 33327, CBS 430.61, DSM 43179, NRBC 13986, JCM 3026, KCC A-0026, NRRL B-2639, RIA 767, VKM Ac-637.

Sequence accession no. (16S rRNA gene): X89935.

Additional comments: the type strain of *Streptosporangium amethystogenes* KCC A-0026 was incorrectly cited as KCC A-2006 (*sic*) on the Approved Lists of Bacterial Names 1980 (Hill et al., 1984). Subsequently, the species was divided into two subspecies (see below).

3a. **Streptosporangium amethystogenes subsp. amethystogenes** Nonomura and Ohara 1960, 407[AL]

This taxon was automatically created by the valid publication of *Streptosporangium amethystogenes* subspecies *fukuiense* Iinuma et al. (1996b) [Rule 40d of the *Bacteriological Code* (1990 Revision); formerly Rule 46]. The description of *Streptosporangium amethystogenes* subsp. *amethystogenes* is given above.

Source: a soil sample collected in Japan.

DNA G+C content (mol%): not determined.

Type strain: ATCC 33327, CBS 430.61, DSM 43179, NRBC 13986, JCM 3026, KCC A-0026, NRRL B-2639, RIA 767, VKM Ac-637.

Sequence accession no. (16S rRNA gene): X89935.

3b. **Streptosporangium amethystogenes subsp. fukuiense** Iinuma, Yokota and Kanamaru 1996a, 1189[VP] (Effective publication: Iinuma, Yokota and Kanamaru 1996b, 41.)

fu.ku.i.en′se. N.L. neut. adj. *fukuiense* of or belonging to Fukui Prefecture, Japan, source of the soil from which the organism was isolated.

Substrate mycelium is brown to dark brown on oatmeal agar, oatmeal-yeast extract agar, and yeast extract-malt extract agar; sparse white aerial hyphae are formed on oatmeal agar but not on the other two media. Spherical spore vesicles (6–8 μm in diameter) are formed. Sporangiospores are ellipsoidal (0.5–0.8 × 0.8–1.2 μm) and have smooth walls. Temperature growth range is 11–36°C. Iodinin crystals are produced on glycerol-asparagine agar, oatmeal agar, tyrosine agar, and yeast extract-malt extract agar.

Milk is neither coagulated or peptonized. Fructose, glucose, maltose, mannose, trehalose, starch, and xylose are used as sole carbon sources, but cellulose, lactose, raffinose, and sorbitol are not. Does not grow in the presence of lysozyme (0.005%, w/v) or sodium chloride (3%, w/v).

Resistant (μg/ml) to cefoxitin (100), but is sensitive to chloramphenicol (50), gentamicin sulfate (100), kanamycin (100), novobiocin (20), rifampin (50), streptomycin (100), and vancomycin hydrochloride (50).

Produces a hematopoietic cytokine inducer.

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain arabinose, glucose, madurose, mannose, and xylose. Muramic acid moieties are *N*-acetylated. The fatty profile includes $C_{16:0}$ iso (4.3%), $C_{16:0}$ (18.8%), $C_{17:0}$ (12.3%), $C_{16:1}$ (13.9%), $C_{17:1}$ (11.3%), $C_{18:1}$ (12.9%), $C_{18:0}$ iso (4.3%), $C_{17:0}$ 10-methyl (10.5%), and $C_{18:0}$ 10-methyl (6.3%). The cellular polar lipid pattern contains phosphatidylethanolamine and unknown glucosamine-containing compounds. The predominant menaquinones are MK-9(H_2) (32.5%) and MK-9(H_4) (59.2%); also contains minor amounts of MK-9(H_0) and MK-9(H_2).

Source: a soil sample collected from Fukui Prefecture, Japan in 1990.

DNA G+C content (mol%): not determined.

Type strain: strain AL-23456, CIP 105397, NBRC 15365, DSM 44779, JCM 10083, NBRC 15365.

Sequence accession no. (16S rRNA gene): AB537172.

Additional comments: the 16S rRNA gene sequence of the type strain of *Streptosporangium amethystogenes* subsp. *fukuiense* has still to be determined. The DNA–DNA relatedness values between this strain and the type strains of *Streptosporangium amethystogenes* subsp. *amethystogenes*, *Streptosporangium roseum*, and *Streptosporangium vulgare* are 55, 12, and 23, respectively.

4. **Streptosporangium carneum** Mertz and Yao 1990, 252[VP]

car´ne.um. L. neut. adj. *carneum* of flesh, intended to mean flesh colored, referring to the color of the aerial spore mass.

Produces an orange substrate mycelium and a bright yellow pink aerial mycelium on Emerson agar, glycerol-asparagine agar, inorganic salts-starch agar, tyrosine agar, yeast-glucose agar, and yeast extract-malt extract agar. A reddish-brown diffusible pigment is formed on tyrosine agar and yeast-glucose agar, and a light brown diffusible pigment on Emerson agar. Aerial hyphae bear abundant spore vesicles on chitin agar, Czapek agar, inorganic salts-starch agar, oatmeal agar, tap water agar, and yeast extract-malt extract agar. Spore vesicles range from 3–9 µm in diameter. Sporangiospores are spherical and a mean of 1.3 µm in diameter.

Catalase, hydrogen sulfide, and phosphatase are produced, but does not hydrolyze allantoin, esculin, hippurate, or urea. Nitrate is not reduced. Milk is not peptonized.

Casein, testosterone, and L-tyrosine are degraded, but adenine, calcium malate, elastin, guanine, hypoxanthine, and xanthine are not.

Acid is produced from cellobiose, fructose, galactose, glucose, lactose, mannose, and trehalose, but not from adonitol, D-arabinose, cellulose, dextrin, dulcitol, ethanol, erythritol, glycerol, glycogen, inositol, inulin, maltose, mannitol, melezitose, melibiose, α-methyl-D-glucoside, raffinose, L-rhamnose, ribose, salicin, sorbitol, L-sorbose, sucrose, xylitol, or xylose.

Acetate and pyruvate are used as sole carbon sources, but benzoate, butyrate, citrate, formate, lactate, malate, mucate, oxalate, propionate, succinate, and tartrate are not.

Growth occurs in the presence of 2% (w/v) sodium chloride. Resistant to antibiotic discs containing bacitracin, cephalothin, gentamicin, lincomycin, penicillin, streptomycin, tetracycline, and tobramycin, but is susceptible to neomycin, oleandomycin, rifampin, vancomycin, and lysozyme.

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain arabinose, madurose, and mannose. The major fatty acids are $C_{14:0}$ (6.9%), $C_{16:0}$ (25.2%), $C_{17:1}$ iso (19.4%), and $C_{18:1}$ iso (6.9%)-like components. The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, and unknown glucosamine-containing components. The predominant menaquinone is MK-9(H_4); also contains a minor amount of MK-9(H_2).

Source: soil collected next to the River Tana in Nairobi, Kenya.

DNA G+C content (mol%): not determined.

Type strain: strain A84575, DSM 44125, NBRC 15562, JCM 9926, NRRL 18437, VKM Ac-2007.

Sequence accession no. (16S rRNA gene): X89938.

5. **Streptosporangium fragile** Shearer, Colman and Nash 1983, 364[VP]

fra′gi.le. L. neut. adj. *fragile* fragile, easily broken (referring to vesicular membrane).

Aerial hyphae (0.5–1.0 µm in diameter) bear spore vesicles which are usually 6–12 µm in diameter. Substrate mycelium is light yellowish pink. Aerial mycelium is white to light pink and the substrate mycelium black on oatmeal agar. Soluble light brown pigment is produced. Spore vesicular membrane is so fragile that it is not detected by light microscopy. The temperature range of growth is 15–45°C.

Produces catalase, hydrogen sulfide, reduces nitrate, and peptonizes milk, but does not hydrolyze allantoin, esculin, hippurate, or urea. Arbutin, casein, and L-tyrosine are degraded, but adenine, guanine, hypoxanthine, keratin, pectin, testosterone, and xanthine are not.

Acid is produced from L-arabinose, cellobiose, dextrin, glucose, *meso*-erythritol, fructose, galactose, glycogen, lactose, maltose, mannitol, mannose, α-methyl-D-glucoside, rhamnose, ribose, salicin, starch, trehalose, and xylose, but not from adonitol, dulcitol, inulin, α-methyl-D-mannoside, melibiose, or raffinose. Citrate, lactate, malate, succinate, and pyruvate are utilized, but benzoate and tartrate are not.

Fructose, inulin, maltose, sorbitol, stachyose, starch, sucrose, and xylose are used as sole carbon sources, but dextrin, lactose, melezitose, melibiose, raffinose, and xylitol (all at 1%, w/v) are not. Acetate, butyrate, citrate, hippurate, malonate, and propionate are used as sole carbon sources (all at 0.1%, w/v).

Grows in the presence of crystal violet (0.0005, w/v), phenol (0.01%, w/v), potassium tellurite (0.005%, w/v), and sodium chloride (1%, w/v), but is inhibited by crystal violet (0.001%, w/v), phenol (0.1%, w/v), phenyl ethanol (0.1, v/v), potassium tellurite (0.01%, w/v), sodium azide (0.001%, w/v), sodium chloride (2%, w/v), and thallous acetate (0.0001%, w/v).

Resistant (µg/ml) to chloramphenicol (5), fusidic acid (0.5), gentamicin sulfate (25), lincomycin (5), neomycin sulfate (5), oleandomycin phosphate (5), rifampin (0.5), sulfomethoxazole (25) and tyrothrecin (5), but is sensitive to amoxycillin (25), azlocillin (25), bacitracin (25), cefoxitin (25), cephaloridine (5), cephradine (25), chloramphenicol (25), clavulanic acid (25), flucloxicillin (50), fusidic acid (5), gentamicin sulfate (50), keflin (25), kefzol (25), lincomycin (25), mecillinam (50), methicillin (250), neomycin sulfate (25), oleandomycin phosphate (25), penicillin G (5), pseudomonic acid (500), rifampin (5), streptomycin sulfate (5), ticacillin (50), and vancomycin hydrochloride (0.5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain madurose. The fatty profile includes $C_{16:0}$ (17.3%), $C_{16:0}$ 10-methyl (4.7%), $C_{18:2}$ (26.0%), $C_{18:1}$ *cis* (35.5%), and $C_{18:0}$ (3.5%). The polar lipid pattern contains diphosphatidylglycerol, phosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, phosphatidylinositol mannosides, and many uncharacterized components. The predominant menaquinones are MK-9(H_2) (15.0%), MK-9(III, VIII-H_4) (60.0%), and MK-9(H_6) (25.0%).

Source: soil taken from a cultivated field in the Northern Province of Sri Lanka.

DNA G+C content (mol%): not determined.

Type strain: SK&F-BC 2496, ATCC 31519, DSM 43847, NBRC 14311, JCM 6242, NRRL B-16437, VKM Ac-1296.

Sequence accession no. (16S rRNA gene): U48992, X89942.

6. **Streptosporangium longisporum** Schäfer 1969, 368[AL]

lon.gi.spo′rum. L. adj. *longus* long; Gr. n. *spora* a seed; N.L. neut. adj. *longisporum* long spored.

Aerial mycelium is sparse and the substrate mycelium is red on oatmeal agar. Pink aerial mycelium is formed on starch agar. Spherical spore vesicles are usually 3–7 μm in diameter, but may be up to 18 μm in diameter. The vesicular wall is relatively thick. Sporangiospores are rod-shaped (0.6–0.9 × 1.5–3.5 μm).

Esculin is hydrolyzed, but hippurate is not. Degrades arbutin, DNA, elastin, RNA, and L-tyrosine, but not guanine, hypoxanthine, keratin, testosterone, or xanthine. Mannose, trehalose, and xylose are used as sole carbon sources, but dextran, lactose, melezitose, melibiose, raffinose, sorbitol, sorbose, stachyose, starch, and xylitol (all at 1%, w/v) are not. Does not use acetate, butyrate, citrate, hippurate, malonate, propionate, or pyruvate as sole carbon sources (all at 0.1%, w/v).

Grows in the presence of crystal violet (0.0005%, w/v), phenol (0.01%, w/v), phenyl ethanol (0.01%, v/v), potassium tellurite (0.001%, w/v), sodium chloride (1.0%, w/v), and thallous acetate (0.0005%, w/v), but is sensitive to crystal violet (0.01%, w/v), phenol (0.01%, w/v), potassium tellurite (0.01%, w/v), sodium azide (0. 01%, w/v), and sodium chloride (4%, w/v).

Resistant (μg/ml) to gentamicin sulfate (5), sulfomethoxazole (3), tetracycline (0.5) and vancomycin hydrochloride (0.5), but is sensitive to amoxycillin (25), azlocillin (25), bacitracin (25), cefoxillin (25), cephaloridine (50), cephradine (25), chloramphenicol (5), clavulanic acid (25), flucloxicillin (50), fusidic acid (0.5), gentamicin sulfate (25), keflin (25), kefzol (25), lincomycin (25), mecillinam (50), methicillin (250), neomycin sulfate (5), oleandomycin phosphate (25), penicillin G (25), pseudomonic acid (500), rifampin (5), streptomycin sulfate (5), tetracycline (5), ticarcillin (50), tyrothrecin (5), and vancomycin hydrochloride (5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysate contains madurose. The fatty acid profile includes $C_{16:0}$ (11.5%), $C_{18:1}$ *cis* (16.0%), C_{110} *trans* (64.0%), and $C_{18:0}$ (6.0%). The cellular polar lipid pattern contains diphosphatidylglycerol, hydroxyphosphatidylethanolamine, phosphatidylinositol, and ninhydrin-positive and sugar positive phospholipids. The predominant menaquinones are MK-9(H_2) (35.1%) and MK-9(III, VIII-H_4) (45%); also contains MK-9(H_0) (12.7%) and MK-9(H_6) (7.2%).

Source: a soil sample collected in Turkey.

DNA G+C content (mol%): not determined.

Type strain: ATCC 25212, CBS 184.69, DSM 43180, NBRC 13141, JCM 3106, KCC A-0106, NRRL B-16783, VKM Ac-696.

Sequence accession no. (16S rRNA gene): U48993, X89944.

7. **Streptosporangium nondiastaticum** Nonomura and Ohara 1969b, 708[AL]

non.di.as.ta′ti.cum. L. pref. *non-* not; N.L. adj. *diastaticus, -a, -um* diastatic; N.L. neut. adj. *nondiastaticum* not starch digesting.

Aerial mycelium is pink and the substrate mycelium yellowish brown to orange on oatmeal-yeast extract agar; also produces a pale yellow-brown soluble pigment on this medium. Does not produce melanin pigments. Good growth at 42°C. Spore vesicles are 10–15 μm in diameter and sporangiospores 1.3 × 1.5 μm.

Esculin is hydrolyzed, but hippurate and urea are not. Arbutin, Tween 80, and L-tyrosine are degraded, but guanine, hypoxanthine, keratin, pectin, testosterone, and xanthine are not.

Adonitol, dextrin, fructose, inulin, maltose, mannose, surcrose, turanose, and xylose are used as sole carbon sources, but dextran, lactose, melezitose, melibiose, raffinose, sorbitol, stachyose, starch, and xylitol (all at 1%, w/v) are not. Acetate and pyruvate are used as sole carbon sources, but butyrate, citrate, hippurate, malonate, and propionate (all at 0.1%, w/v) are not.

Grows in the presence of crystal violet (0.0005%, w/v), phenol (0.01%, w/v), potassium tellurite (0.01%, w/v), and sodium chloride (2.0%, w/v), but is sensitive to crystal violet (0.001%, w/v), phenol (0. 1%, w/v), phenyl ethanol (0.1%, v/v), sodium azide (0.001%, w/v), sodium chloride (4%, w/v), and thallous acetate (0.0001%, w/v).

Resistant (μg/ml) to amoxycillin (50), azlocillin (50), bactracin (50), cefoxitin (50), cephaloridine (5), clavulanic acid (500), chloramphenicol (5), flucloxicillin (50), fusidic acid (0.5), gentamicin sulfate (5), ketlin (50), kefzol (250), lincomycin (50), mecillinam (500), methicillin (500), neomycin sulfate (5), oleandomycin phosphate (50), penicillin G (50), pseudomonic acid (500), sulfomethoxazole (25), tetracycline (5), ticarcillin (50), and vancomycin hydrochloride (0.5), but is sensitive to amoxycillin (250), azlocillin (250), cefoxitin (250), cephaloridine (25), cephradine (25), chloramphenicol (25), flucloxicillin (250), fusidic acid (5), gentamicin sulfate (25), kefzol (500), oleandomycin phosphate (250), rifampin (0.5), streptomycin sulfate (5), tetracycline (25), ticarcillin (250), and vancomycin hydrochloride (5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates do not contain madurose. The fatty acid profile includes $C_{14:0}$ iso (2.7%), $C_{15:0}$ iso (1.9%), $C_{15:0}$ (11.2%), $C_{16:0}$ iso (13.2%), $C_{16:1}$ (2.0%), $C_{16:0}$ (5.2%), $C_{16:0}$ 10-methyl (3.6%), $C_{17:0}$ anteiso (19.8%), $C_{17:0}$ (4.4%), $C_{17:0}$ 10-methyl (22.1%), $C_{18:2}$ (5.5%), $C_{18:1}$ *trans* (1.7%), and $C_{18:0}$ 10-methyl (1.5%). The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, phosphatidylinositol mannosides, phosphatidylmethylethanolamine, and several uncharacterized components. The predominant menaquinones are MK-9(H_2) (55.0%) and MK-9(III, VIII-H_4) (40%); also contains MK-9(H_0) (2.0%) and MK-9(H_6) (3.0%).

Source: a soil sample collected in Japan.

DNA G+C content (mol%): not determined.

Type strain: ATCC 27101, CBS 800.70, DSM 43848, NBRC 13990, JCM 3114, VKM Ac-1299.

Sequence accession no. (16S rRNA gene): U48994, X70426, X89945.

8. **Streposporangium pseudovulgare** Nonomura and Ohara 1969b, 708[AL]

pseu.do.vul.ga′re. Gr. adj. *pseudês* false; L. neut. adj. *vulgare* a specific epithet; N.L. neut. adj. *pseudovulgare* similar in appearance to strain of *Streposporangium vulgare*.

Aerial mycelium is pink and the substrate mycelium yellowish brown to orange on oatmeal-yeast extract agar; a yellowish brown soluble pigment is also produced on this medium. Spore vesicles are 7–10 µm in diameter and sporangiospores 1.2 × 1.5 µm. Good growth at 42°C; also grows at 55°C.

Esculin is hydrolyzed, but hippurate and urea are not. Nitrate is reduced. Degrades arbutin, keratin, pectin, Tween 80, and L-tyrosine, but not guanine, hypoxanthine, testosterone, or xanthine.

Glucose, fructose, inulin, maltose, mannose, turanose, and xylose are used as sole carbon sources, but dextrin, lactose, melezitose, melibiose, raffinose, sorbitol, stachyose, starch, sucrose, and xylitol (all at 1%, w/v) are not. Similarly, pyruvate is metabolized, but acetate, butyrate, citrate, hippurate, malonate, and propionate (all at 0.1%, w/v) are not.

Grows in the presence of crystal violet (0.001, w/v), phenol (0.01%, w/v), phenyl ethanol (0.2%, v/v), potassium tellurite (0.01%, w/v), sodium azide (0.005%, w/v), sodium chloride (2%, w/v), and thallous acetate (0.001%, w/v), but is sensitive to crystal violet (0.01%, w/v), phenol (0.1%, w/v), phenyl ethanol (0.3, v/v), sodium azide (0.02%, w/v), and sodium chloride (4%, w/v).

Resistant (µg/ml) to amoxycillin (250), azlocillin (250), bacitracin (25), cefoxitin (250), cephaloridine (25), cephradine (25), chloramphenicol (5), clavulanic acid (250), flucloxicillin (50), fusidic acid (0.5), gentamicin sulfate (50), keflin (50), kefzol (500), lincomycin (5), mecillinam (500), methicillin (500), neomycin sulfate (5), oleandomycin phosphate (250), penicillin G (25), pseudomonic acid (500), rifampin (25), streptomycin sulfate (5), sulfomethoxazole (25), tetracycline (5), ticarcilliin (500), and vancomycin hydrochloride (0.5), but is sensitive to azlocillin (500), bacitracin (50), cephaloridine (50), cephradine (50), chloramphenicol (25), clavulanic acid (500), flucloxicillin (250), fusidic acid (5), lincomycin (25), penicillin G (50), streptomycin sulfate (25), tetracycline (25), and vancomycin hydrochloride (5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain madurose. The fatty acid profile includes $C_{14:0}$ (1.3%), $C_{15:0}$ (3.5%), $C_{16:0}$ iso (5.6%), $C_{16:1}$ (3.9%), $C_{16:0}$ (25.2%), $C_{17:0}$ anteiso (9.1%), $C_{17:0}$ (4.9%), $C_{17:0}$ 10-methyl (3.2%), $C_{18:1}$ *cis* (11.9%), $C_{18:1}$ *trans* (23.5%), and $C_{18:0}$ (4.7%) The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, phosphatidylinositol mannosides, phosphatidylmethylethanolamine, and several uncharacterized components. The predominant menaquinones are MK-9(H_2) (60.4%) and MK-9(III, VIII-H_4) (28.0%); also contains MK-9(H_0) (11.6%).

Source: a soil sample collected in Japan.

DNA G+C content (mol%): not determined.

Type strain: ATCC 27100, CCRC 16308, CCTCC AA 97010, DSM 43181, NBRC 13991, JCM 3115.

Sequence accession no. (16S rRNA gene): U48995, X70428, X89946.

9. **Streptosporangium purpuratum** Zhang, Jiang and Chen 2005, 723[VP]

pur.pu.ra´tum. L. neut. adj. *purpuratum* clad in purple-violet, referring to the colony color.

Substrate mycelium is deep red to deep purplish-red on Bennett's agar, glycerol-asparagine agar, inorganic salts-starch agar, oatmeal agar, oatmeal-yeast extract agar, and yeast extract-malt extract agar; diffusible pigments are not formed on any of these media. Pinkish-white aerial mycelium is formed on most of these media. The exceptions are Bennett's agar, which does not support aerial hyphae, and yeast-extract-malt agar, where the aerial mycelium is sparse. Spherical spore vesicles, usually 2–5 µm in diameter, are formed singly or in clusters on the aerial mycelia on HV and oatmeal agars. Sporangiospores are spherical to oblate. The optimal temperature for growth is 28°C; also grows at 50°C. The optimal pH for growth is 7.2.

Hydrolyzes hippurate. Nitrate is reduced. Cellulose and uric acid are degraded. Cellobiose, fructose, glucose, sucrose, and xylose are used as sole carbon sources, but dextrin, erythrose, lactose, mannose, melibiose, α-methyl-D-glucoside, sorbitol, and sorbose are not.

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain glucose and madurose. The major fatty acids are $C_{15:0}$ (23.7%), $C_{16:0}$ (42.0%), and $C_{17:0}$ (24.9%). The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, and glucosamic-containing components. The predominant menaquinones are MK-9(H_0), MK-9(H_2), and MK-9(H_4).

Source: a soil sample collected from Yunnan Province, China.

DNA G+C content (mol%): 69.1 (T_m).

Type strain: strain CY-15110, CCRC 16308, CCTCC AA 97010, DSM 44688, JCM 14926.

Sequence accession no. (16S rRNA gene): AF191735.

Additional comments: Streptosporangium purpuratum CY-15110[T] is most closely related to the type strains of *Streptosporangium longisporum* (55.3%), *Streptosporangium pseudovulgare* (45.2%), *Streptosporangium nondiastaticum* (43.6%), and *Streptosporangium roseum* (43.3%) based on DNA–DNA relatedness data (Zhang et al., 2005).

10. **Streptosporangium subroseum** Zhang, Jiang and Chen 2002, 1237[VP]

sub.ro′se.um. N.L. neut. adj. *subroseum* pale rose colored.

Abundant white-pinkish aerial mycelium is formed on Bennett's agar, glycerol-asparagine agar, and oatmeal-yeast extract agar. The substrate mycelium is yellowish-brown. Soluble pigments are not produced. Spherical spore vesicles, commonly 4–10 µm in diameter, are formed on the aerial mycelium on HV agar and oatmeal agar. Sporan-

giospores are spherical or oval-shaped. The temperature range for growth is 10–42°C; the optimal temperature is 30°C; does not grow at 50°C.

Nitrate is reduced. Degrades cellulose. Cellobiose, fructose, glucose, mannose, raffinose, L-rhamnose, sucrose, and xylose are used as sole carbon sources.

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain glucose, madurose, ribose, and rhamnose. The major fatty acids are $C_{16:0}$ (5.8%), $C_{17:0}$ (11.4%), $C_{18:0}$ (32.1%), and $C_{19:0}$ (18.6%). The diagnostic polar lipid is phosphatidylethanolamine. The predominant menaquinones are MK-9(H_6), MK-9(H_2), and MK-9(H_4).

Source: a soil sample collected in Yunnan Province, China.

DNA G+C content (mol%): 71.2 (T_m).

Type strain: strain CY-7113, ATCC 21807, BCRC 16302, CCTCC 97008, DSM 44662, JCM 11962, KCC A-0281.

Sequence accession no. (16S rRNA gene): AF191734.

Additional comments: the specific epithet *subroseum* is a N.L. neut. adj. not a L. neut adj. as cited in the paper by Zhang et al. (2002). In the abstract of the paper the type strain BCRC (formerly CCRC) 16302 is erroneously cited as CRC 16302.

11. **Streptosporangium violaceochromogenes** Kawamoto, Takasaka, Okachi, Kohakura, Tkahashi and Nara 1975, 358[AL]

vi.o.la.ce.o.chro.mo′ge.nes. L. adj. *violaceus* violet; Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *violaceochromogenes* producing violet color.

Aerial mycelium is pink and the substrate mycelium pale yellow on oatmeal agar. Violet or rose colored pigments are produced on nutrient, Bennett's, and Emerson agars. Spherical spore vesicles (5–9 µm in diameter) with irregular surfaces are borne on long sporangiosphores on the aerial mycelium. Sporangiospores are oval to cylindrical (0.8–0.9 × 1.2–1.6 µm). Does not require biotin or thiamine for growth. Grows from 25–40°C, optimally between 30–37°C, and from pH 6.0–8.5, optimally at pH 7.3.

Reduces nitrate. Milk is coagulated and peptonized. L-Tyrosine is degraded, but cellulose is not.

Fructose, glucose, mannose, starch, sucrose, and xylose are used as sole carbon sources.

Additional phenotypic features are shown in Table 276.

Does not contain madurose in whole-organism hydrolysates. The menaquinones are MK-9(H_0) (19.0%), MK-9(H_2) (50.0%), and MK-9(III, VIII-H_4) (31.0%).

Source: a soil sample collected from a swamp in Yoshioka village, Kitaguninagum, Gunma, Japan.

DNA G+C content (mol%): not determined.

Type strain: ATCC 21807, DSM 43849, NBRC 15560, JCM 3281, KCC A-0281, NRRL B-16784.

Sequence accession no. (16S rRNA gene): U48997, X89951.

12. **Streptosporangium vulgare** Nonomura and Ohara 1960, 407[AL]

vul.ga′re. L. neut. adj. *vulgare* common.

Aerial mycelium is pink and the substrate mycelium yellowish-brown to orange on oatmeal-yeast extract agar; a pale yellow to yellow soluble pigment is also formed on this medium. Does not produce melanin pigments. Spore vesicles are 6–8 µm in diameter,- and sporangiospores are 1.0–1.2 × 1.5–1.9.

Hydrolyzes esculin, but not urea. Nitrate is reduced. Degrades arbutin, elastin, RNA, and L-tyrosine, but not guanine, hypoxanthine, keratin, testosterone, Tween 20, or xanthine. Dextrin, inulin, mannose, sucrose, trehalose, and xylose are used as sole carbon sources, but dextran, fructose, lactose, melezitose, melibiose, raffinose, sorbitol, sorbose, stachyose, starch, and xylitol (all at 1%, w/v) are not. Does not use acetate, butyrate, citrate, hippurate, malonate, or pyruvate as sole carbon sources (all at 0.1%, w/v).

Grows in the presence of crystal violet (0.001%, w/v), phenol (0.01%, w/v), phenyl ethanol (0.2%, v/v), potassium tellurite (0.01%, w/v), sodium chloride (2%, w/v), and thallous acetate (0.001%, w/v), but is sensitive to crystal violet (0.01%, w/v), phenol (0. 1%, w/v), phenyl ethanol (0.3% v/v), sodium azide (0.001%, w/v), and sodium chloride (4%, w/v).

Resistant (µg/ml) to amoxycillin (500), azlocillin (500), bacitracin (50), celoxitin (250), cephaloridine (250), cephadrine (500), chloramphenicol (25), clavulanic acid (50), flucloxicillin (50), fusidic acid (0.5), keflin (250), kefzol (500), lincomycin (5), mecillinam (500), methicillin (500), oleandomycin phosphate (250), penicillin G (50), pseudomonic acid (500), sulfomethoxazole (25), ticarcillin (50), and tyrothrecin (5), but is sensitive to bacitracin (50), clavulanic acid (500), flucloxicillin (250), fusidic acid (0.5), lincomycin (25), penicillin G (250), rifampin (0.5), tetracycline (5), ticarcillin (500), and vancomycin hydrochloride (5).

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain madurose. The fatty acid profile includes $C_{12:0}$ (1.9%), $C_{14:0}$ (6.3%), $C_{15:0}$ (2.1%), $C_{16:0}$ iso (23.6%), $C_{16:0}$ (7.7%), $C_{16:0}$ 10-methyl (2.9%), $C_{17:0}$ (5.4%), $C_{17:0}$ 10-methyl (22.6%), $C_{18:1}$ cis (2.4%), $C_{18:0}$ (2.1%), and $C_{18:0}$ 10-methyl (5.6%). The cellular polar lipid pattern contains diphosphatidylglycerol, hydroxyphosphatidylethanolamine, phosphatidylethanolamine, phosphatidylinositol, and ninhydrin-positive and sugar-positive phospholipids. The predominant menaquinones are MK-9(H_0) (32.2%), MK-9(H_2) (56.7%), and MK-9(III, VIII-H_4) (15.1%).

Source: a soil sample collected from a paddy field in Anjo, Aichi Prefecture, Japan.

DNA G+C content (mol%): not determined.

Type strain: ATCC 33329, CBS 431.61, DSM 43802, NBRC 13985, JCM 3028, KCC A-0028, NRRL B-2633, RIA 765, VKM Ac-641.

Sequence accession no. (16S rRNA gene): U48999, X89955.

13. **Streptosporangium yunnanense** Zhang, Jiang and Chen 2005, 723[VP]

yun.nan.en′se. N.L. neut. adj. *yunnanense* of or pertaining to Yunnan, a province of south-west China.

Aerial mycelium is pale-pink to yellowish-pink and the substrate mycelium is brown to brownish-yellow on Bennett's agar, glycerol-asparagine agar, inorganic salts-starch agar, oatmeal agar, oatmeal-yeast extract agar, and yeast extract-malt extract agar; a pale brown diffusible pigment is formed on all of these media, except Bennett's agar and yeast extract-malt extract agar. Spherical spore vesicles (4–20 µm in diameter) are formed singly or in clusters on HV and oatmeal agars. Sporangiospores are spherical or oblate. The temperature range for growth is 10–42°C, does not grow at 50°C. Optimal pH is 7.2.

Hippurate is hydrolyzed and nitrate reduced. Degrades cellulose and uric acid. Cellobiose, glucose, and sucrose are used as sole carbon sources, but dextrin, erythrose, fructose, inositol, lactose, mannose, mannitol, melibiose, α- methyl-D-glucoside, raffinose, sorbitol, sorbose, and xylose are not.

Additional phenotypic features are shown in Table 276.

Whole-organism hydrolysates contain glucose, madurose, and rhamnose. The major fatty acids are $C_{16:0}$ (14.7%), $C_{17:0}$ (5.0%), $C_{18:0}$ (10.0%), and $C_{19:0}$ (29.6%). The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, phosphatidylmethylethanolamine, and glucosamine-containing components. The predominant menaquinones are MK-9(H_0), MK-9(H_2), and MK-9(H_4).

Source: a soil sample collected from Yunnan Province, China.

DNA G+C content (mol%): 71.1 (T_m).

Type strain: strain CY-11007, CCRC 16307, CCTCC AA 97009, DSM 44663, JCM 14927.

Sequence accession no. (16S rRNA gene): AF191733.

Additional comments: Streptosporangium yunnanense CY-11007^T is most closely related to the type strains of *Streptosporangium nondiastaticum* (56.8%) and *Streptosporangium pseudovulgare* (53.1%) on the basis of DNA–DNA relatedness data (Zhang et al., 2005).

Species *incertae sedis*

1. **"Streptosporangium rubrum"** Potekhina 1965, 292.

ru'brum. L. neut. adj. *rubrum* red

A pale pink to white substrate mycelium and a white to pale pink aerial mycelium is formed on Czapek agar. Forms spherical spore vesicles (6.0–14 µm in diameter) and branched sporangiophores (0.5–1.2 × 1.6–27 µm). Spores are typically spherical (0.8 × 1.4 µm), but may be ovoid or rod-shaped.

Milk is peptonized and nitrates weakly reduced to nitrites. Cellulose and starch are degraded, but gelatin is not.

Source: a dark gray forest soil.

DNA G+C content (mol%): not determined.

Reference strain: DSM 44095.

Sequence accession no. (16S rRNA gene): X89950.

Genus II. **Acrocarpospora** Tamura, Suzuki and Hatano 2000, 1170^{VP}

Tomohiko Tamura

A.cro.car.po.spo'ra. Gr. adj. *akros* uttermost, topmost, highest, at the top, end; Gr. n. *karpos* fruit, harvest; Gr. fem. n. *spora* a seed; N.L. fem. n. *Acrocarpospora* an organism forming spores like fruits on the terminal mycelium

Gram-stain-positive bacterium that is not-acid-fast and forms **branching hyphae**.

Non-fragmentary substrate mycelia are present. Spherical and club shaped structures are borne on the tips of the **aerial mycelium**. These structures contain coiled or straight spore chains. Spores are oval or short rod-like (0.6–0.8 × 0.7–1.0 µm) with a smooth surface and nonmotile. **Strictly aerobic**. Good growth occurs at 20–30°C. Shows good growth on oatmeal agar. In general, the vegetative mycelia are pale yellow and aerial hyphae are white. Cell walls contain glutamate, alanine, and *meso*-diaminopimelate. Wall chemotype is III (Lechevalier and Lechevalier, 1970b), and the peptidoglycan type is presumed to be A1γ (Schleifer and Kandler, 1972). Madurose, glucose, and galactose are detected in whole cell sugars. Major cellular fatty acids are $C_{16:0}$ iso, $C_{17:0}$ 10-methyl, $C_{17:1}$, and $C_{17:0}$. The major menaquinones are MK-9(H_4) and MK-9(H_2), and small amounts of MK-9(H_6) are present. Phosphatidylethanolamine is present as a diagnostic phospholipid. Mycolic acids are absent. The acyl type of cell wall is acetyl. The type species is *Acrocarpospora pleiomorpha*.

DNA G+C content (mol%): 68–69.

Type species: **Acrocarpospora pleiomorpha** Tamura, Suzuki and Hatano 2000, 1170^{VP}.

Further descriptive information

The sporangium forms two types of structures, club-shaped and various sized spherical bodies. In 7- and 14-d-old cultures, the various sized spherical bodies are commonly found; the club-shaped structures are infrequent.

Although species of *Acrocarpospora* possess similar fatty acids, there are differences in the quantities of some of the most abundant ones (Table 277). For instance, *Acrocarpospora pleiomorpha* contains high levels of $C_{13:0}$, and *Acrocarpospora corrugate* contains low levels of $C_{16:0}$ iso. Similarly, while the physiological

responses of the species of *Acrocarpospora* are generally similar, some differences are noted (Table 278).

Enrichment and isolation procedures

Acrocarpospora pleiomorpha strain R-31^T was isolated from soil in Louisiana, USA, and *Acrocarpospora macrocephala* strain R-55^T was isolated from soil in Saitama prefecture, Japan.

The type strain of *Acrocarpospora corrugata* was isolated from beach sand (pH 7.8) at Freshfield, Lancashire, United Kingdom, by using the dilution plate technique on starch-casein medium containing antifungal antibiotics (Williams and Sharples, 1976). In this isolation procedure, most of the actinomycetes appearing on the plates were micromonosporas, and *Streptosporangium corrugatum*-like colonies accounted for less than 1% of the total.

Maintenance procedures

Strains of the genus *Acrocarpospora* are maintained by freezing in water containing 10–30% glycerol at −70°C. Lyophilization of suspensions in 10% skim milk +1% monosodium glutamate and l-drying in 0.01 M potassium phosphate buffer (pH7.0) containing 3% monosodium glutamate are also recommended for long-term preservation.

Differentiation of the genus *Acrocarpospora* from other genera

The genus *Acrocarpospora* forms club-shaped or spherical sporangia at the heads of the aerial mycelia and produces spores by fragmentation of hyphae and the hyphal sheath, which either expands to form the sporangial envelope or remains around the spore chains. Although the morphological characteristics and spore development of isolates are similar in many respects to those of *Streptosporangium* species, there are differences in the irregular shape and variable size of spore vesicles. Under the light microscope, the isolates appear similar to *Nonomuraea pusilla*, which develops pseudosporangia, rather than to the majority of *Streptosporangium* species. The genus *Acrocarpospora* contains MK-9(H_4) as the major menaquinone and is differentiated from the genus *Herbidospora*, which has MK-10(H_4) as a predominant menaquinone.

Taxonomic comments

The phylogenetic tree based on 16S rRNA gene sequence analysis indicates that three species of the genus *Arcocarpospora* form a branch within the family *Streptosporangiaceae* of the order *Streptosporangiales* (Tamura et al., 2000). The genus *Herbidospora* is the most closely related genus to *Acrocarpospora*. *Acrocarpospora corrugata* was originally proposed as *Streptosporangium corrugatum* by Williams and Sharples (1976) and transferred to the genus *Acrocarpospora* by Tamura et al. (2000).

List of species of the genus *Acrocarpospora*

1. **Acrocarpospora pleiomorpha** Tamura, Suzuki and Hatano 2000, 1170[VP]

ple.i.o.mor′pha. Gr. adj. *pleios* full; Gr. n. *morphe* form; N.L. fem. adj. *pleiomorpha* pleiomorphic, in various shapes.

Gelatin liquefaction is negative. Hydrolyzes starch. Does not decompose calcium malate. Coagulation of milk is weak. Reduction of nitrate is positive. Glucose, raffinose, rhamnose, and mannitol are utilized, but xylose, arabinose, sucrose, fructose, and inositol are not. As diagnostic phospholipids, phosphatidylethanolamine, ninhydrin positive, and sugar positive phospholipids are present.

Source: soil.

DNA G+C content (mol%): 69 (HPLC).

Type strain: R-31, JCM 10983, NBRC 16267.

Sequence accession no. (16S rRNA gene): AB006174.

2. **Acrocarpospora corrugata** (Williams and Sharples 1976) Tamura, Suzuki and Hatano 2000, 1170[VP] (*Streptosporangium corrugatum* Williams and Sharples 1976, 45)

cor.ru.ga′ta. L. fem. part. adj. *corrugata* wrinkled.

Aerial hyphae bearing globose vesicles (1.0–5.0 µm diameter) containing coiled chains of about 20 spores and club-shaped structures (3.5–8.0 × 0.75–1.00 µm) containing three to eight spores. Spores from both structures are nonmotile, 0.8–1.0 × 0.6–0.7 µm, with prominent longitudinal ridges and terminal annular ridges. Spore walls become considerably thickened, reaching 150 nm. Aerial mycelium and spore-containing structures are white, the reverse side of the colony is pale buff, and no soluble pigment is produced.

The predominant menaquinones are MK-9(H_2) and MK-9(H_4), and the major cellular fatty acids are $C_{17:1}$ and $C_{17:0}$ (Kudo and Seino, 1987) along with $C_{17:0}$ 10-methyl. The positions of hydrogenation of menaquinone MK-9(H_4) are III and VIII, as in the case of the genus *Streptosporangium* (Collins et al., 1988; Stackebrandt et al., 1994). Galactose and trace amount of madulose are detected in the whole cell sugars (Stackebrandt et al., 1994). In addition to the diagnostic phospholipid, phosphatidylethanolamine, hydroxy-phosphatidylethanolamine, diphosphatidylglycerol, and phosphatidylinositol are present (Stackebrandt et al., 1994). Numerical analysis of the phenotypic characteristics were studied by Whitham et al. (1993).

Type strain: ATCC 29331, BCRC 12360, DSM 43316, JCM 3181, KCTC 9431, NBRC 13972, NCIMB 11120.

Sequence accession no. (16S rRNA gene): AB188150.

3. **Acrocarpospora macrocephala** Tamura, Suzuki and Hatano 2000, 1170[VP]

ma.cro.ce′pha.la. Gr. adj. *makrokephalos* long-headed; N.L. fem. n. *macrocephala* large head.

Gelatin liquefaction is negative. Hydrolyzes starch. Does not decompose calcium malate. Coagulates milk. Glucose, raffinose, rhamnose, mannitol, and sucrose are utilized, but xylose, arabinose, fructose, and inositol are not. As diagnostic phospholipids, phosphatidylethanolamine, and ninhydrin positive and sugar positive phospholipids are present.

Source: soil.

DNA G+C content (mol%): 68 (HPLC).

Type strain: R-55, JCM 10982, NBRC 16266.

Sequence accession no. (16S rRNA gene): AB025318.

Genus III. **Herbidospora** Kudo, Itoh, Miyadoh, Shomura and Seino 1993, 327[VP]

Takuji Kudo

Her.bi.do.spo′ra. L. adj. *herbidus* grassy; Gr. n. *spora* a seed; N.L. fem. n. *Herbidospora* organism forming spores like grass.

Aerobic, stains Gram-positive but non-acid-fast. **Non-fragmented branching vegetative hyphae** are produced, but distinct **aerial hyphae are not formed**. Straight and short chains of nonmotile, smooth-surfaced, oval spores (10–30 spores per chain) are borne on the tips of the sporophores which are derived from the vegetative mycelia in clusters. Cell walls contain *meso*-diaminopimelate and *N*-acetylated muramic acid, but lack a significant amount of glycine (cell-wall type III). Whole-cell hydrolysates contain trace amounts of madurose (whole cell sugar pattern B). Contains phosphatidylethanolamine and its derivatives and glucosamine-containing phospholipids as diagnostic phospholipids (phospholipid type PIV). Cellular fatty acid composition is characterized by $C_{17:0}$ 10-methyl, $C_{17:1}$ ω8c, $C_{16:0}$ iso, and $C_{17:0}$ (fatty acid type 3c). The predominant isoprenoid quinone is a tetrahydrogenated menaquinone with ten isoprene units, and the hydrogenation occurs at units III and IX [MK-10(III,IX-H_4)]. MK-10(H_2), MK-10(H_0), MK-10(H_6), and MK-9(III,VIII-H_4) are also present as minor components. Mycolic acids are absent.

DNA G+C content (mol%): 69–73.

Type species: **Herbidospora cretacea** Kudo, Itoh, Miyadoh, Shomura and Seino 1993, 327[VP].

Further descriptive information

The genus *Herbidospora* was first described in 1993 with a single species *Herbidospora cretacea*, and no additional species were proposed for 16 years. From 2009 onward, an additional four species, *Herbidospora osyris* (Li et al., 2009), *Herbidospora yilanensis*, and *Herbidospora daliensis* (Tseng et al., 2010) and *Herbidospora sakaeratensis* (Boondaeng et al., 2011) were described in succession. Based on phylogenetic analysis using 16S rRNA gene

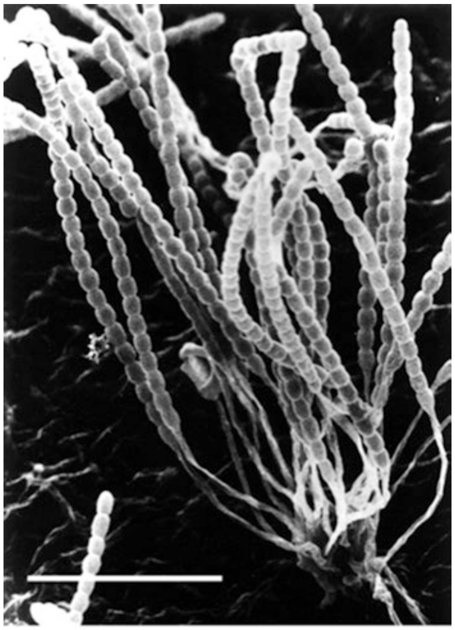

FIGURE 367. Scanning electron micrograph of *Herbidospora cretacea* JCM 8554. Bar = 10 μm.

sequences, the genus *Herbidospora* is monophyletic and within the family *Streptosporangiaceae*. In fact, the morphological and chemotaxonomic characteristics of the members are almost homogeneous and distinct from other genera belonging to the family.

Macroscopically, they produce white or brownish yellow aerial masses on some media, but microscopic observation reveals that relatively long sporophores bearing spore chains develop directly in clusters from the substrate mycelia located at the agar surface (Figure 367). This morphological characteristic is unique among other members of the family *Streptosporangiaceae*.

The chemotaxonomic characteristics of the genus, with the exception of menaquinone composition, are shared by other genera of the family *Streptosporangiaceae*, i.e. cell-wall type III, *N*-acetylated muramic acid in the cell walls, whole cell sugar pattern B, phospholipids type PIV, and cellular fatty acid type 3c. On the other hand, the members of the genus *Herbidospora* contain MK-10(H_4) as a major component, while all of the other genera in the family *Streptosporangiaceae* have menaquinones with nine isoprene units. This difference in the length of the side chain shows the apparent boundary of this genus. The tetrahydrogenation of the side chain of the *Herbidospora* menaquinone occurs at isoprene unit III and IX, while the tetrahydrogenation of those of the other genera belonging to the family *Streptosporangiaceae* occurs at units III and VIII. It is thought that these modes of tetrahydrogenation represent a common mechanism in that the third double bond from the naphthoquinone moiety and the second double bond from the ω-terminus are hydrogenated. Among actinobacteria, this hydrogenation pattern is unique to the family *Streptosporangiaceae*.

Isolation and maintenance procedures

Herbidospora strains have been isolated from soil, the sediment of a river, decayed leaves, the bark of a pine tree, the petals of flowers, and a surface-sterilized tissue of a plant. Humic acid-vitamin agar (Hayakawa and Nonomura, 1987b) was often used as an isolation medium, but there is no information on enrichment. The organisms grow relatively well on general complex agar media used for filamentous actinomycetes such as oatmeal agar (ISP 3), yeast extract-malt extract agar (ISP 2) or yeast-starch agar, but good sporulation occurs on only a few media such as ISP 3, oatmeal-nitrate agar, and ISP 2 agar. As most species of this genus require vitamin B complex, they grow poorly on defined media. They can be stored in 10% glycerol or DMSO solution at −80°C, lyophilized with 10% skim milk, or L-dried with 0.1 M phosphate buffer (pH 7.0) plus 3% monosodium glutamate and 1.5% adonitol for long-term preservation.

Differentiation of the genus *Herbidospora* from other genera

As shown in Figure 368, the genus *Herbidospora* is a member of the family *Streptosporangiaceae*, and the closest relative is the genus *Acrocarpospora*. The genus *Herbidospora* shares chemot-

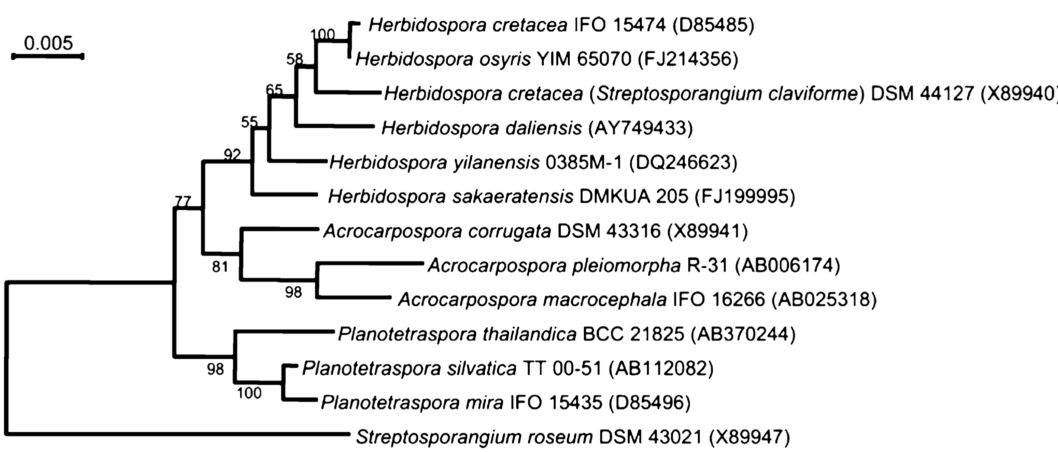

FIGURE 368. Neighbor joining tree based on 16S rRNA gene sequences showing the phylogenetic relationships among *Herbidospora* species and related taxa. Numbers represent bootstrap values for each branch (1000 replicates).

axonomic characteristics with other genera of the family *Streptosporangiaceae*, but it is readily differentiated from them by its distinctive morphology and menaquinone composition. The menaquinones of the genus *Herbidospora* are mainly composed of MK-10(H_4), but other members of the family including the closest genus, *Acrocarpospora*, contain menaquinones with nine isoprene units. Morphologically, the genus *Acrocarpospora* is characterized by formation of spherical and club-shaped sporangium-like structures, but the genus *Herbidospora* does not produce sporangium-like structures. The genus *Actinocorallia* sometimes shows similar morphology to *Herbidospora*, but this genus belongs to the family *Thermomonosporaceae* and has quite different chemotaxonomic characteristics.

Taxonomic comments

Streptosporangium claviforme was described as a sporangium-producing actinomycete (Petrolini et al., 1992), but its morphology is identical with that of the genus *Herbidospora*. In the original description, the authors thought that the chains of spores were enveloped by "sporangial" walls. However, the term "sporangium" has been defined more accurately, and even spores of streptomycetes have sheath-like structures. *Streptosporangium claviforme* also has MK-10(III, IX-H_4) as a major component. Tamura et al. (2000) indicated that the DNA–DNA relatedness between the type strains of *Streptosporangium claviforme* and *Herbidospora cretacea* was 80%, and Boondaeng et al. (2011) reclassified *Streptosporangium claviforme* as a later synonym of *Herbidospora cretacea*.

Differentiation of species of the genus *Herbidospora*

Five species are currently known, and they share morphological and chemotaxonomic characteristics. Thus, differentiation of the species depends on physiological characteristics. However, the accurate boundary of the species cannot be determined physiologically because the descriptions of the species, except for *Herbidospora cretacea*, are based on a single strain. Identification at the species level should be performed by using differential characteristics shown in Table 279 and 16S rRNA gene analysis as well as DNA–DNA hybridization.

List of species of the genus *Herbidospora*

1. **Herbidospora cretacea** Kudo, Itoh, Miyadoh, Shomura and Seino 1993, 327[VP]

cre.ta′ce.a. L. fem. adj. *cretacea* chalk-like.

Vegetative mycelia are yellow to brown on most media. When sporulation occurs, the surface of the colony is white or brownish yellow. Good sporulation occurs on oatmeal agar (ISP 3) and oatmeal-nitrate agar. Diffusible pigment and melanoid pigments are not produced. Mesophilic (optimal growth at 28°C) and neutrophilic (optimal growth at pH 7.0–8.0). No growth occurs in the presence of 3% NaCl.

Decomposes casein, deoxyribonucleic acid, esculin, hypoxanthine, and starch, but not adenine, arbutin, guanine, keratin, tyrosine, and xanthine. Utilizes L-arabinose, cellobiose, D-fructose, D-galactose, D-glucose, maltose, D-mannitol, D-mannose, D-ribose, starch, sucrose, and D-xylose as a sole carbon source, but not adonitol, cellulose, dulcitol, *i*-erythritol, glycerol, *myo*-inositol, melezitose, and raffinose. Utilizes fumaric acid, DL-lactic acid, L-malic acid, and succinic acid, but not benzoic acid, citric acid, mucic acid, oxalic acid, propionic acid, and L-tartaric acid. Sensitive to lysozyme, gentamicin, novobiocin, rifampin, streptomycin, and vancomycin. Requires thiamine for growth.

Source: soil, decayed leaves, bark of pine tree, and petal of daisy fleabane; type strain was isolated from soil collected in Saitama, Japan.

DNA G+C content (mol%): 69–70 (HPLC).

Type strain: K-319, ATCC 51904, BCRC 16356, DSM 44071, JCM 8553, KCTC 9335, NBRC 15474, NCIMB 13372, VKM Ac-1997.

Sequence accession no. (16S rRNA gene): D85485.

2. **Herbidospora daliensis** Tseng, Yang and Yuan 2010, 1171[VP]

da.li.en′sis. N.L. fem. adj. *daliensis* of or pertaining to Dali city, Taiwan, where the type strain was isolated.

Vegetative mycelia are yellowish white to yellowish brown on most media. When sporulation occurs, the surface of the colony is white or brownish yellow. Good sporulation occurs on oatmeal agar (ISP 3). Diffusible and melanoid pigments are not produced. Neutrophilic. Growth occurs at 20–40°C. NaCl tolerance is 5%.

Decomposes starch but not adenine, hypoxanthine, tyrosine, and xanthine. L-Arabinose, fructose, galactose, glucose, maltose, mannitol, melezitose, raffinose, rhamnose, and sucrose are utilized. Adonitol, benzoic acid, cellobiose, cellulose, dulcitol, erythritol, fumaric acid, glycerol, *myo*-inositol, DL-lactic acid, L-malic acid, mannose, melibiose, mucic acid, propionic acid, D-ribose, salicin, D-sorbitol, succinic acid, L-tartaric acid, trehalose, and xylose are not utilized. Sensitive to lysozyme. Requires *p*-aminobenzoic acid and *myo*-inositol for growth. Biotin, nicotinic acid, pantothenic acid, pyridoxine, riboflavin, and thiamine are not required for growth.

Morphological and chemical characteristics are given in the description of the genus.

Source: sediment of a river in Dali city, Taiwan.

DNA G+C content (mol%): 70.7 (HPLC).

Type strain: 0385M-1, FIRDI 004, BCRC 16876, LMG 24336, NBRC 106372.

Sequence accession no. (16S rRNA gene): AY749433.

3. **Herbidospora osyris** Li, Zhao, Qin, Zhu, Xu and Li 2009, 3126[VP]

o.sy′ris. L. n. *osyris* a plant (probably the broom-like goosefoot or summer cypress), and also a botanical genus name (*Osirys*); N.L. gen. n. osyris, of *Osyris* the plant genus from which this species was isolated.

Vegetative mycelia are yellowish white to yellowish brown on most media. When sporulation occurs, the surface of the colony is white. Moderate sporulation occurs on yeast-extract-malt extract agar (ISP 2) and YIM 38 agar. A diffusible pigment is not produced. Growth occurs at 10–37°C and pH 6.0–8.0. NaCl tolerance is up to 3%.

Catalase is produced. Negative for the Voges–Proskauer and methyl red tests, for the oxidase reaction, for production of H_2S, for nitrate reduction, and for milk coagulation and peptonization. Tweens 20 and 40 and urea are hydrolyzed, but Tween 80, gelatin, starch, and cellulose are not hydrolyzed. Utilizes amygdalin, arbutin, cellobiose, esculin, D-fructose, D-galactose, glycerol, *myo*-inositol, maltose, D-mannitol, D-mannose, melibiose, raffinose, D-ribose, salicin, sodium DL-malate, D-tagatose, trehalose, turanose, and D-xylose as sole carbon sources. D-Adonitol, D-arabinose, dulcitol, erythritol, D-lactose, L-rhamnose, D-sorbitol, L-sorbose, and xylitol are not utilized. Adenine, L-alanine, L-cysteine, L-cystine, L-histidine, L-lysine, L-phenylalanine, L-proline, L-serine, L-threonine, L-tyrosine, and xanthine can be used as sole nitrogen sources, but L-arginine, L-asparagine, L-glutamic acid, glycine, hypoxanthine, DL-methionine, and L-valine cannot.

Morphological and chemical characteristics are given in the description of the genus.

Source: type strain was isolated from a surface sterilized plant sample, *Osyris wightiana* Wall. *ex* Wight, collected from Yunnan province, south-west China.

DNA G+C content (mol%): 70.4 (HPLC).

Type strain: YIM 65070, CCTCC AA 208019, DSM 45214, JCM 16900, NBRC 106571.

Sequence accession no. (16S rRNA gene): FJ214356.

4. **Herbidospora sakaeratensis** Boondaeng, Suriyachadkun, Ishida, Tamura, Tokuyama and Kitpreechavanich 2011, 779[VP]

sa.ka.e.ra.ten′sis. N.L. fem. adj. *sakaeratensis* of or pertaining to Sakaerat Biosphere Reserve, the source of soil from which the type strain was isolated.

Vegetative mycelia are yellow to yellowish brown. A melanoid pigment is not produced. Growth occurs at 20–40°C and pH 6.0–9.0. NaCl tolerance is up to 1.5%.

Utilizes L-arabinose, D-fructose, D-galactose, D-glucose, D-mannitol, D-mannose, starch, sucrose, and D-xylose as sole carbon sources, but not dulcitol, *myo*-inositol, maltose, melezitose, D-raffinose, L-rhamnose, D-ribose, and D-sorbitol. Utilizes

fumaric acid, L-malic acid, and succinic acid, but not benzoic acid and mucic acid. Cellulose degradation, gelatin liquefaction, nitrate reduction, and milk peptonization are negative.

Morphological and chemical characteristics are given in the description of the genus.

Source: a soil sample collected in Sakaerat Biosphere Reserve in Nakhonratchasima, Thailand.

DNA G+C content (mol%): 73 (HPLC).

Type strain: DMKUA 205, BCC 11662, NBRC 102641.

Sequence accession no. (16S rRNA gene): FJ199995.

5. **Herbidospora yilanensis** Tseng, Yang and Yuan 2010, 1170[VP]

yi.lan.en′sis. N.L. fem. adj. *yilanensis* of or pertaining to Yilan county, Taiwan, where the type strain was isolated.

Vegetative mycelia are yellowish white to yellow on most media. When sporulation occurs, the surface of the colony is white or brownish yellow. Moderate sporulation occurs on oatmeal agar (ISP 3), oatmeal-nitrate agar, and glycerol-asparagine agar (ISP 5). Diffusible and melanoid pigments are not produced. Neutrophilic. Growth occurs at 20–40°C. NaCl tolerance is 1%.

Decomposes starch but not adenine, esculin, hypoxanthine, tyrosine, and xanthine. Fructose, fumaric acid, galactose, glucose, glycerol, DL-lactic acid, *myo*-inositol, maltose, mannitol, mannose, melibiose, melezitose, raffinose, rhamnose, salicin, sucrose, succinic acid, and trehalose are utilized. Adonitol, L-arabinose, benzoic acid, cellobiose, cellulose, dulcitol, erythritol, L-malic acid, mucic acid, propionic acid, D-ribose, D-sorbitol, L-tartaric acid, and xylose are not utilized. Sensitive to lysozyme. *p*-Aminobenzoic acid, *myo*-inositol and thiamine are required for growth. Biotin, nicotinic acid, pantothenic acid, and pyridoxine are not required for growth.

Morphological and chemical characteristics are given in the description of the genus.

Source: sediment of a dry lake, Yilan, a county in north Taiwan.

DNA G+C content (mol%): 70.6 (HPLC).

Type strain: 0351M-12, FIRDI 003, BCRC 16875, LMG 24337, NBRC 106371.

Sequence accession no. (16S rRNA gene): DQ246623.

Genus IV. **Microbispora** Nonomura and Ohara 1957, 307[AL] emend. Zhang, Wang and Ruan 1998a, 418

Christopher M. M. Franco

Mi.cro.bi.spo′ra. Gr. adj. *mikros* small; L. adv. num. *bis* twice; Gr. n. *spora* a seed; N.L. fem. n. *Microbispora* the small two-spored (organism).

Aerobic, Gram-stain-positive, non-acid–alcohol-fast, nonmotile, mesophilic, and thermophilic actinobacteria **which form stable, highly branched substrate and aerial mycelia**. **Spore chains, typically containing two spores, are borne longitudinally on short aerial hyphae. Spores are slightly oval to cylindrical (1.0–1.4 to 1.2–1.7 µm in diameter) and have smooth surfaces**. **Mesophilic species grow from 20–37°C, with thermophilic species up to 55°C**. Most species require B vitamins, particularly thiamine, for growth. Chemoorganotrophic with an oxidative type of metabolism. **Cell walls contain *N*-acetylated muramic acid and major amounts of *meso*-diaminopimelic acid; peptidoglycan type is A1γ. Whole-cell hydrolysates contain madurose** and complex mixtures of saturated, unsaturated, iso-, anteiso-, and branched chain fatty acids. **Predominant menaquinones have nine isoprene units with hydrogenation at positions III and IV [MK-9(III, IV-H_4), MK-9(H_2), and MK-9(H_0)]. Major phospholipids are phosphatidylcholine and unknown glucosamine-containing compounds, but no phosphatidylglycerol**. Natural habitat is soil, plant litter, and as epiphytes and endophytes of plants.

DNA G+C content (mol%): 68–73.

Type species: **Microbispora rosea** Nonomura and Ohara 1957, 307[AL].

Further descriptive information

Phylogeny. The genus *Microbispora* contains 13 species including *Microbispora rosea*, *Microbispora aerata*, *Microbispora amethystogenes*, *Microbispora chromogenes*, *Microbispora corallina*, *Microbispora diastatica*, *Microbispora indica*, *Microbispora karnatakensis*, *Microbispora mesophila*, *Microbispora parva*, *Microbispora siamensis*, *Microbispora thermodiastatica*, and *Microbispora thermorosea*. The type strains of these species form a distinct phyletic line in the *Streptosporangiaceae* 16S rRNA gene tree with *Microtetraspora*, *Arcocarpospora*, *Herbidospora*, and *Nonomuraea* (Figure 369) being the most closely related genera. The 16S rRNA gene sequence similarities of the *Microbispora* type strains fall within the range 95.1–99.2% (Wang et al., 1996b). The corresponding DNA–DNA relatedness values range from 27–80% (Nakajima et al., 1999).

Cell morphology. Microbisporae form characteristic pairs of spores on the aerial hyphae or short sporophores; the latter may be short so that the spores appear sessile. Buds formed on the aerial hyphae or tips of a side branch swell and then separate by a side wall. The sporophore of *Microbispora rosea* partially encloses the basal spore giving the appearance of a ball-and-socket joint (Williams, 1970). Mature spores are easily detached from the sporophore and each other when placed in water. Spores from most species of *Microbispora* have a smooth surface and are found along the entire length of the aerial hyphae (Figures 30.11, 30.12 from *Bergey's Manual*, previous edition, Nonomura, 1989b). Single spores have been reported for *Microbispora mesophila* (Zhang et al., 1998a).

Nutrition and growth conditions. Most microbisporae require B-vitamins for growth on synthetic media (Nonomura and Ohara, 1971d) but are readily cultivated on rich media including glucose-yeast extract (Waksman, 1967), oatmeal supplemented with yeast extract (Shirling and Gottlieb, 1966), and yeast extract-malt extract (Shirling and Gottlieb, 1966) agars. Mesophilic microbisporae grow between 20 and 37°C, but the thermophilic strains grow better at 37–45°C.

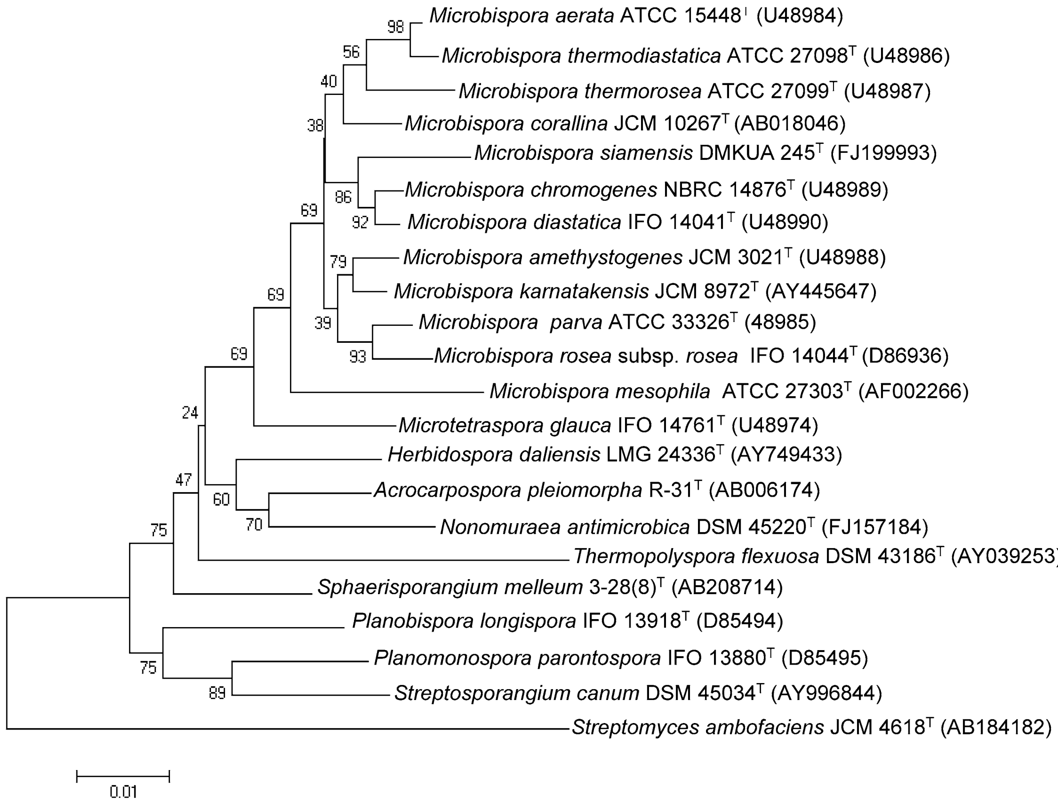

FIGURE 369. 16S rRNA gene-based neighbor-joining tree showing the phylogenetic relationships between *Microbispora* species and between selected microorganisms belonging to the family *Streptosporangiaceae*. The numbers on the branches indicate the percentage bootstrap values of 1000 replicates. *Streptomyces ambofaciens* JCM 9374^{T} was used as an outgroup.

Cell-wall composition. *Microbispora* strains contain *meso*-diaminopimelic acid as the major wall diamino acid, have a wall chemotype III, and their whole-organism hydrolysates contain madurose (Lechevalier and Lechevalier, 1970b; Nonomura and Ohara, 1971d). The wall peptidoglycan is of the type A1γ and contains *N*-acetylated muramic acid (Nakajima et al., 1999). *Microbispora* contains phosphatidylethanolamine, phosphatidylinositol, diphosphatidylglycerol, phosphatidylinositol mannosides, and ninhydrin and sugar positive phospholipids (phospholipid type IV *sensu* Lechevalier et al., 1977), major proportions of tetrahydrogenated menaquinones with nine isoprene units saturated at sites III and VIII, and substantial proportions of MK-9(H_4, H_2, and H_0) (Kroppenstedt et al., 1990; Nakajima et al., 1999). Members of the genus contain complex mixtures of fatty acids that include major proportions of hexadecanoic acid ($C_{16:0}$), heptadecanoic acid ($C_{17:0}$), 14-methylpentadecanoic ($C_{16:0}$ iso), and 10 methylheptadecanoic ($C_{17:0}$ 10-methyl) acids (Table 281; Kroppenstedt et al., 1990; Nakajima et al., 1999).

Ecology. Microbisporae are common in soils, including soils rich in leaf litter (Nonomura, 1984; Nonomura and Ohara, 1969a), and even desert soils (Takahashi et al., 1996). They have also been isolated in large numbers from surface-sterilized fallen leaves (Matsumoto et al., 1998). Okazaki et al. (1995) collected monocotyledon leaves from 170 plants to obtain 57 *Microbispora* species from the leaf surfaces. The prevalence of strains belonging to *Microbispora* from healthy plant leaves was confirmed by another study by the same group (Kizuka et al., 1998). Endophytic *Microbispora* species were isolated from surface-sterilized wheat roots (Coombs and Franco, 2003) and a range of plants (Taechowisan et al., 2003). Polyethylene-degrading thermophilic strains have been isolated in Taiwan (Hoang et al., 2007; Tseng et al., 2007). Secondary metabolites have been reported from a number of strains; these include a prolyl endopeptidase inhibitor from *Microbispora rosea* and *Microbispora indica* strains (Kimura et al., 1997), tyrosine kinase inhibitors from *Microbispora rosea* strains (Kajiura et al., 1998), antibiotics phenazins and phenoxazinones from *Microbispora aerata* (Gerber and Lechevalier, 1964), glucosylquestiomycin (Igarashi et al., 1998) and bispolides from *Microbispora* species (Okujo et al., 2007), and herbicides from a *Microbispora rosea* strain (Kizuka et al., 1998).

Enrichment and isolation procedures

Microbispora are present in low numbers in soils and constitute a minor component of the actinomycete population (Hayakawa and Nonomura, 1987b). Therefore, selective isolation media

such as AV*(Nonomura and Ohara, 1969a), Chitin-V† (Nonomura, 1984), and HV‡ agars (Hayakawa and Nonomura, 1987b) together with pretreatments of samples were developed to yield *Microbispora* species from soils. *Microbispora mesophila* was isolated as "*Thermomonospora mesophila*" using MGA-SE agar§ (Nonomura and Ohara, 1971b). In later improvements to the selective isolation procedures, soils collected from farms in Japan were air-dried, heated to 120°C for 1 h, and treated with 1.5% phenol and 0.03% chlorhexidine gluconate (Hayakawa et al., 1991b) before plating on HV containing 20 mg nalidixic acid. Matsumoto et al. (1998) used glycerol asparagine agar** or water plus 1% proline agar containing the antibiotics nystatin, benomyl, cycloserine, and nalidixic acid to obtain 34 strains of *Microbispora* from a total of 77 actinomycetes obtained from fallen leaves.

Microbispora rosea, *Microbispora amethystogenes*, *Microbispora chromogenes*, *Microbispora diastatica*, and *Microbispora parva* were isolated from soil samples collected in Japan using soil extract agar (Nonomura and Ohara, 1957, 1960). *Microbispora corallina* and *Microbispora siamensis* were isolated from forest soils in Thailand with dilution plating on HV agar (Boondaeng et al., 2009; Nakajima et al., 1999), while *Microbispora indica* and *Microbispora karnatakensis* were isolated from soil samples from India using undisclosed methods (Rao et al., 1987).

Maintenance procedures

Well-sporulated agar slant cultures can be maintained at 4°C for 3–4 months. Recommended media for mesophilic strains are oatmeal agar-YG and glycerol agar (C1 medium†† supplemented with 0.5% (w/v) glycerol) for thermophilic strains. Suspensions of spores and hyphae in glycerol (20%, v/v) can be stored in liquid nitrogen at −80°C. Lyophilization is recommended for long-term preservation by placing the spores and mycelia in skimmed milk.

Differentiation of the genus *Microbispora* from other genera

Microbispora strains can be distinguished from the genera *Microtetraspora* and *Nonomuraea* by their ability to form characteristic longitudinal pairs of spores on short aerial hyphae with smooth spore surfaces, except for *Microbispora mesophila* which is monosporic. *Microtetraspora* species have characteristic chains of four spores on distinct sporophores, whereas *Nonomuraea* species bear chains of spores.

Taxonomic comments

Eleven *Microbispora* species were included in the last edition of *Bergey's Manual of Systematic Bacteriology* (Nonomura, 1989b); these include *Microbispora aerata* Gerber and Lechevalier 1964, *Microbispora amethystogenes* Nonomura and Ohara 1960, *Microbispora bispora* Henssen 1957, *Microbispora chromogenes* Nonomura and Ohara 1960, *Microbispora diastatica* Nonomura and Ohara 1960, *Microbispora echinospora* Nonomura and Ohara 1971b, *Microbispora parva* Nonomura and Ohara 1960, *Microbispora rosea* Nonomura and Ohara 1957, *Microbispora thermodiastatica* Nonomura and Ohara 1969b, *Microbispora thermorosea* Nonomura and Ohara 1969b, and *Microbispora viridis* Miyadoh et al. 1985. Later two others were proposed as valid species, *Microbispora indica* and *Microbispora karnatakensis* (Rao et al., 1987). On the basis of differences in chemotaxonomy and DNA–DNA relatedness, "*Microbispora echinospora*" and "*Microbispora viridis*" were transferred to the genus *Actinomadura* as *Actinomadura echinospora* and *Actinomadura rugatobispora*, respectively (Kroppenstedt et al., 1990; Miyadoh et al., 1990). Miyadoh et al. (1990) further proposed the combination of the 10 extant species, other than *Microbispora bispora*, into two subspecies of *Microbispora rosea* on the basis of DNA–DNA relatedness and chemotaxonomy. "*Microbispora rosea* subsp. *rosea*" contains *Microbispora rosea*, *Microbispora amethystogenes*, *Microbispora chromogenes*, *Microbispora diastatica*, *Microbispora echinospora*, *Microbispora indica*, *Microbispora karnatakensis*, and *Microbispora parva*; whereas "*Microbispora rosea* subsp. *aerata*" contains *Microbispora aerata*, *Microbispora thermodiastatica* and *Microbispora thermorosea*. However, Wang et al. (1996b) called into question the taxonomic status of these combinations, a view supported by Ochi et al. (1991) based on electrophoretic mobility of ribosomal AT-L30 protein. The clear differences observed for *Microbispora bispora* were analyzed by Wang et al. (1996a) who found that, on the basis of 16S rRNA gene sequence dissimilarity, two strains of this species were sufficiently different from the other species of *Microbispora* as well as other members of the family *Streptosporangiaceae* to be transferred to a new genus, *Thermobispora*, as *Thermobispora bispora*. Subsequently, Zhang et al. (1986a) proposed the reclassification of the monosporic *Thermomonospora mesophila* to the genus *Microbispora*, as *Microbispora mesophila*, on the basis of 16S rRNA gene sequence similarity and reported chemotaxonomic properties. Later *Microbispora corallina* was proposed by Nakajima et al. (1999) for two new mesophilic strains isolated from deciduous dipterocarp forest soils in Thailand, and *Microbispora siamensis* was proposed for a thermotolerant strain isolated from a soil sample from the same country (Boondaeng et al., 2009).

Differentiation of species of the genus *Microbispora*

Microbispora species can be distinguished from one another by using a combination of morphological, chemotaxonomic, nutritional, and physiological characteristics (Table 280 and Table 281).

*AV agar: arginine, 0.3 g; glucose, 1 g; glycerol, 1 g; K_2HPO_4, 0.3 g; Mg $SO_4 \cdot 7H_2O$, 0.2 g; NaCl, 0.3 g; agar, 15 g; B-vitamins (0.5 mg each of *p*-aminobenzoic acid, calcium pantothenate, inositol, niacin, pyridoxine-HCl, riboflavin, thiamine HCl, and 0.25mg biotin); distilled water 1 liter; antibiotics (Actidione, 50 mg; nystatin, 50 mg; polymixin B, none or 4 mg; penicillin G, none or 0.8 mg); pH 6.4.

† Chitin-V agar: colloidal chitin, 2 g; K_2HPO_4, 0.35 g.; KH_2PO_4, 0.15 g; $MgSO_4 \cdot 7H_2O$, 0.2 g; NaCl, 0.3 g; $CaCO_3$, 0.02 g; Fe $SO_4 \cdot 7H_2O$, 0.01 g;. $ZnSO_4 \cdot 7H_2O$, 1 mg; $MnCl_2$, 1 mg;. agar, 18 g,; β-vitamins, as for AV agar; distilled water 1 liter; Actidione, 50 mg; pH 7.2.

‡ HV agar: humic acid, 1 g; $CaCO_3$, 0.02 g; Fe $SO_4 \cdot 7H_2O$, 0.01 g; KCl, 1.7g; Mg $SO_4 \cdot 7H_2O$, 0.05 g; Na_2HPO_4, 0.5 g.; agar, 15 g; β-vitamins, as for AV agar; distilled water 1 liter; Actidione, 50 mg; pH 7.2.

§ MGA-SE agar:glucose, 2 g; L-asparagine, 1 g; K_2HPO_4, 0.5g; soil extract, 200 ml; agar, 20 g; distilled water 800 ml; antibiotics (Actidione, 50 mg; nystatin, 12.5 mg; polymixin B, 4 mg; peniclllin G, 0.8 mg); pH 8.0.

**Glycerol-asparagine agar: L-asparagine, 0.1 g; glycerol, 1 g; K_2HPO_4, 1 mg; $FeSO_4 \cdot 7H_2O$, 0.5 g; $ZnSO_4 \cdot 7H_2O$, 1 mg; $MnCl_2 \cdot 4H_2O$, 1 mg;.agar, 15 g; distilled water 1 liter; antibiotics (Benlate, 20 mg; cycloserine, 50 mg; nalidixic acid, 25 mg; nystatin, 12.5 mg).

†† C1 medium (Nonomura and Ohara, 1969b): casamino acids, 2 g; K_2HPO_4, 0.3 g; $MgSO_4 \cdot 7H_2O$, 0.01 g; NaCl, 0.3 g; Fe $SO_4 \cdot 7H_2O$, 10 mg;. $ZnSO_4 \cdot 7H_2O$, 1 mg; $CuSO_4 \cdot 5H_2O$, 1 mg; B-vitamins (0.5 mg each of *p*-aminobenzoic acid, calcium pantothenate, inositol, niacin, pyridoxine-HCl, riboflavin, thiamine HCl, and 0.25 mg biotin); agar, 20 g; distilled water 1 liter, pH 7.2.

TABLE 280. Characteristics differentiating the type strains of *Microbispora* species[a,b]

Characteristic	*M. rosea*	*M. aerata*	*M. amethystogenes*	*M. chromogenes*	*M. corallina*	*M. diastatica*	*M. indica*	*M. karnatakensis*	*M. mesophila*	*M. parva*	*M. siameensis*	*M. thermodiastatica*	*M. thermorosea*

[a]Cultured at 37°C. Data from Miyadoh et al. (1990), Nakajima et al. (1999), and Boondaeng et al. (2009).

List of species of the genus *Microbispora*

1. **Microbispora rosea** Nonomura and Ohara 1957, 307[AL]

ro′se.a. L. fem. adj. *rosea* rose-colored.

Aerial hyphae white at first, becoming pale pink with the formation of spores on oatmeal yeast extract agar. Spores are oval or round (1.4–1.6 µm) (Figure 370). Good to moderate growth on Emerson's, Bennett's, C.B., nutrient, and oatmeal and soil agars. An orange substrate mycelium is formed on oatmeal agar with 0.1% peptone. B vitamins are required for growth. Grows between 17–35°C, but not at 55°C. Optimal pH range for growth is 6.0–7.0. Degrades casein, hypoxanthine, and testosterone.

Source: soil.

DNA G+C content (mol%): 69.9 (HPLC).

Type strain: ATCC 12950, DSM 43839, JCM 3006, NBRC 14044, NRRL B-2632, VKM Ac-634.

Sequence accession no. (16S rRNA gene): D86936.

2. **Microbispora aerata** (Gerber and Lechevalier 1964) Cross 1974, 859[AL] ("*Waksmania aerata*" Gerber and Lechevalier 1964, 598.)

a.e.ra′ta. L. fem. part. adj. *aerata* covered with bronze.

Poor or moderate growth on oatmeal-yeast extract agar with white to pale pink aerial mycelium, with production of iodinin. Spores are oval or round (1.3–1.5 µm). Grows between 28–55°C. Optimal pH range for growth is 6.0–7.0.

Slight production of melanoid pigments; starch hydrolyzed; nitrites produced from nitrates; slight hydrolysis of gelatin; peptonization of milk. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): 72% (T_m).

Type strain: ATCC 15448, DSM 43176, JCM 3076, NBRC 12581, VKM Ac-1507.

Sequence accession no. (16S rRNA gene): U48984.

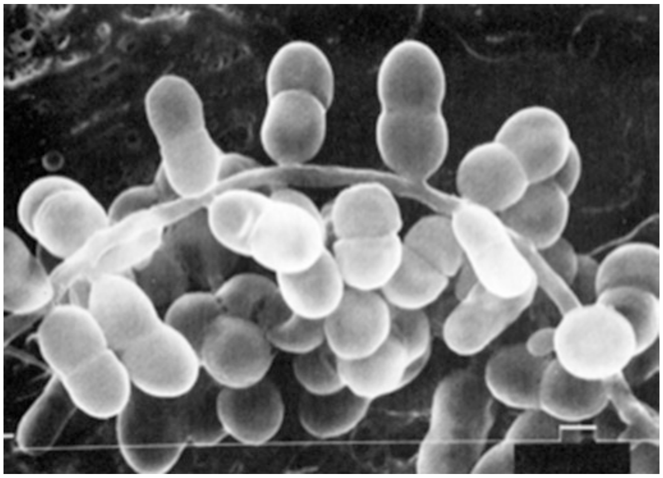

FIGURE 370. Morphology of *Microbispora rosea*: paired spores on hyphae. Scanning electron micrograph. Bar interval = 10 μm.

3. **Microbispora amethystogenes** Nonomura and Ohara 1960, 404[AL]

am.e.thys.to′gen.es. L. adj. *amethystinus* amethyst colored; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. part. adj. *amethystogenes* producing violet-colored (crystals).

Aerial mycelium is pink; soluble pigment is pale yellowish brown on oatmeal-yeast extract agar. Abundant violet crystals observed after 30 d. On oatmeal-peptone agar, the substrate mycelium is light brown to brownish gray with scant aerial mycelium. Spores are oval or round (1.3–1.6 μm). Poor growth on glycerine, nutrient, and glycerol-asparagine agar-yeast extract agars with no aerial mycelium. Grows between 17–35°C, but not at 55°C. Optimal pH range for growth is 6.0–7.0.

No melanoid pigments produced; no starch hydrolysis; gelatin liquefied; slight peptonization of milk; nitrites produced from nitrates. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): 70.5 (HPLC).

Type strain: DSM 43164, JCM 3021, NBRC 101907, NRRL B-2637.

Sequence accession no. (16S rRNA gene): U48988.

4. **Microbispora chromogenes** Nonomura and Ohara 1960, 404[AL]

chro.mo′ge.nes. Gr. n. *chroma* color; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing: N.L. part. adj. *chromogenes* producing color.

Aerial mycelium is pink; soluble pigment is dark-purple gray on oatmeal-yeast extract agar. On potato agar, the substrate mycelium is pale orange, aerial mycelium pale pink with pale yellow soluble pigment. A dark green soluble pigment is produced on glycerin agar. Spores are oval or round (1.3–1.6 μm). Good to moderate growth on glycerin, glycerol-asparagine-yeast extract, nutrient, potato, and starch-yeast extract agars. Grows between 17–35°C, but not at 55°C. No melanoid pigments produced; starch hydrolyzed; gelatin liquefied; no peptonization of milk; nitrites produced from nitrates. Requires thiamine and low levels of biotin.

Source: soil.

DNA G+C content (mol%): 70 (HPLC).

Type strain: DSM 43165, JCM 3022, NBRC 14876, NRRL B-2634.

Sequence accession no. (16S rRNA gene): U48989.

5. **Microbispora diastatica** Nonomura and Ohara 1960, 404[AL]

di.a.sta′ti.ca. N.L. fem. adj. *diastatica* starch hydrolyzing.

Aerial mycelium is pink; soluble pigment is pale yellow on oatmeal–yeast extract agar. On oatmeal–peptone agar, the substrate mycelium is pale yellowish brown covered entirely with pale pink aerial mycelium. Spores are oval or round (1.3–1.6 μm). Good growth on glycerine and nutrient agars with no aerial mycelium. Grows between 17–35°C, but not at 55°C. Optimal pH range for growth is 6.0–7.0.

No melanoid pigments produced; starch hydrolyzed; gelatin liquefied; no peptonization of milk; and nitrites not produced from nitrates. Utilizes rhamnose. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): 68.9 (HPLC).

Type strain: JCM 3023, KCC A-0023, NBRC 14041, NBRC 101785, NRRL B-2630.

Sequence accession no. (16S rRNA gene): U48990.

6. **Microbispora mesophila** (Nonomura and Ohara 1971b) Zhang, Wang and Ruan 1998a, 418[VP] (*Thermomonospora mesophila* Nonomura and Ohara 1971b, 899)

me.so.phi′la. Gr. n. *mesos* middle; Gr. fem. adj. *philê* loving; N.L. fem. adj. *mesophila* middle (temperature) loving.

Colonies on agar media are small, entire, raised, with a brown reverse color and abundant white aerial mycelium, with spores either sessile or on short sporophores. Spores with smooth surfaces either oval or round (1.5–2 μm). Good to moderate growth on oatmeal, yeast extract-malt extract, nutrient, starch-yeast extract agars. Very poor growth on glycerol-asparagine agar. Optimum temperature for growth is 35–40°C. Optimum growth at pH 7.5–8.0.

No melanoid pigments produced; starch hydrolyzed; gelatin liquefied weakly; peptonization of milk; nitrites produced from nitrates. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): not determined.

Type strain: ATCC 27303, CIP 105593, DSM 43048, NBRC 14179, JCM 3151, NRRL B-16986, VKM Ac-1953.

Sequence accession no. (16S rRNA gene): AB006170, AF002266.

7. **Microbispora parva** Nonomura and Ohara 1960, 403[AL]

par′va. L. fem. adj. *parva* little, small (growth).

Poor growth on oatmeal agar with a faint yellow soluble pigment; violet crystals observed after 30 d at 30°C. Aerial mycelium is pink; soluble pigment is white to pale pink on oatmeal-yeast extract agar. On oatmeal-peptone agar, the substrate mycelium is pale yellowish brown to light brown with scant aerial mycelium. Spores are oval or round (1.3–1.6 μm). Good to moderate growth on glycerine, nutrient, potato, and glycerol-asparagine agar-yeast extract agars.

Grows between 17–35°C, but not at 55°C. Optimal pH range for growth is 6.0–7.0.

No melanoid pigments produced; no starch hydrolysis; slight hydrolysis of gelatin; slight peptonization of milk. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): 69.8 (HPLC).

Type strain: ATCC 33326, JCM 3024, KCC A-0024, NRRL B-2629.

Sequence accession no. (16S rRNA gene): U48985.

8. **Microbispora siamensis** Boondaeng, Ishida, Tamura, Tokuyama and Kitpreechavanich 2009, 3138[VP]

si.a.men.sis. NL. fem. adj. *siamensis* of or pertaining to Siam, the old name of Thailand, the source of the soil from which the type strain was isolated.

Substrate mycelia are colorless to yellow on most media; yellow and green soluble pigments are produced. Oval spores with smooth surfaces. Good growth on yeast-extract-malt extract agar with moderate pink spores.

Temperature growth range is 25–50°C. No growth in the presence of 3% (w/v) NaCl.

Citric acid, L-malic acid, and succinic acid are used, but benzoic acid, fumaric acid, and mucic acid are not. L-Arabinose, D-fructose, D-galactose, D-glucose, D-lactose, D-mannitol, D-mannose, and sucrose are used as sole carbon sources, but dulcitol, inositol, maltose, D-melezitose, D-raffinose, L-rhamnose, and D-sorbitol are not. Cellulose is not degraded; gelatin not liquefied; no nitrites produced from nitrates; no peptonization of milk.

Source: soil.

DNA G+C content (mol%): 68 (HPLC).

Type strain: DMKUA 245, BCC 14407, NBRC 104113.

Sequence accession no. (16S rRNA gene): FJ199993.

9. **Microbispora thermodiastatica** Nonomura and Ohara 1969b, 706[AL]

ther.mo.di.a.sta′ti.ca. Gr. adj. *thermos* hot; N.L. fem. adj. *diastatica* starch-hydrolyzing; N.L. fem. adj. *thermodiastatica* heat-loving, starch-hydrolyzing.

Poor or moderate growth on oatmeal-yeast extract agar with white to pale yellow aerial mycelium at 40°C. Good growth on yeast-starch agar with white to pale yellow brown aerial mycelium. On glucose agar, the aerial mycelium is pale pink with no soluble pigment. Spores are oval or round (1.3–1.5 µm). Grows between 35–55°C. Optimal pH range for growth is 6.0–7.0.

No melanoid pigments produced; starch hydrolyzed; no nitrites produced from nitrates; slight hydrolysis of gelatin; peptonization of milk. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): 70.3 (HPLC).

Type strain: ATCC 27098, JCM 3110.

Sequence accession no. (16S rRNA gene): U48986.

10. **Microbispora thermorosea** Nonomura and Ohara 1969b, 707[AL]

ther.mo.ro′se.a. Gr. adj. *thermos* hot; L. fem. adj. *rosea* rose-colored; N.L. fem. adj. *thermorosea* heat-loving, rose-colored.

Poor or moderate growth on oatmeal agar. Good growth on yeast-starch agar; aerial mycelium is white to pale yellowish brown. Spores are oval or round (1.3–1.6 µm). Grows between 35–55°C. Optimal pH range for growth is 6.0–7.0.

No melanoid pigments produced; no starch hydrolysis; no nitrites produced from nitrates; slight hydrolysis of gelatin; slight peptonization of milk. Requires thiamine and low levels of biotin.

DNA G+C content (mol%): 70.1 (HPLC).

Type strain: ATCC 27099, JCM 3111.

Sequence accession no. (16S rRNA gene): U48987.

Species *incertae sedis*

1. **Microbispora corallina** Nakajima, Kitpreechavanich, Suzuki and Kudo 1999, 1766[VP]

co.ral′li.na. L. fem. adj. *corallina* coral colored.

Substrate mycelia pinkish to brownish red on most media and yellowish soluble pigments produced. Oval spores (0.8~1.2 µm). Good growth on glucose-asparagine agar +1% yeast extract; poor aerial mycelium pink, substrate mycelium russet, yellow diffusible pigment. Good growth on inorganic salts-starch agar +1% yeast extract with cherry pink aerial mycelium, coral substrate mycelium, no diffusible pigment. Good growth on oatmeal agar with scant pink aerial mycelium, yellow diffusible pigment. Good growth on yeast extract-starch agar with poor pink aerial mycelium, dark red substrate mycelium, yellow diffusible pigment. Good growth on yeast-extract-malt extract agar with moderate pink aerial mycelium and deep reddish brown substrate mycelium; no diffusible pigment. Temperature growth range: 17–25°C. No growth in the presence of NaCl 3% (w/v).

Casein and esculin are degraded, but adenine, elastin, guanine, hypoxanthine, keratin, testosterone, tyrosine, xanthine, xylan, and DNA are not. Amylase is produced. Amygdalin, L-arabinose, D-cellobiose, D-fructose, D-galactose, D-glucose, glycerol, *meso*-inositol, D-lactose, maltose, D-mannitol, D-mannose, D-melezitose, D-melibiose, D-ribose, salicin, D-sorbitol, sucrose, D-trehalose, and D- xylose are used as sole carbon sources, but adonitol, D-arabitol, dulcitol, iso-erythritol, inulin, D-raffinose, L-rhamnose, and xylitol are not.

DNA G+C content (mol%): 71.2–71.5 (HPLC).

Type strain: DF-32, = ATCC BAA-20, DSM 44682, NBRC 16416, JCM 10267.

Sequence accession no. (16S rRNA gene): AB018046.

2. **Microbispora indica** Rao, Prabhu, Sridhar, Venkateswarlu and Actor 1987, 184[VP]

in.di.ca. L. fem. adj. *indica* pertaining to India, the source of the soil from which the type strain was isolated.

Substrate mycelia yellow to yellowish brown on most media and orange yellowish soluble pigments produced on oatmeal agar. Oval spores (1.2~1.8 µm). Poor growth on glycerol-asparagine agar with no aerial mycelium, colorless substrate mycelium, no diffusible pigment. Good growth on glycerol-asparagine agar +1% yeast extract with light gray aerial mycelium, yellow brown substrate mycelium, no diffusible pigment. Good growth on oatmeal agar with pink aerial mycelium, violet-orange substrate mycelium, orange-yellow diffusible pigment. Good growth on yeast-extract-malt extract agar with light gray aerial mycelium, yellow brown substrate mycelium, no diffusible pigment. Temperature growth range: 28–50°C. No growth in the presence of NaCl 3% (w/v).

Casein is degraded, but amylase is not produced. L-Arabinose, D-glucose, and L-rhamnose are used as sole carbon sources, but glycerol and *meso*-inositol are not.

DNA G+C content (mol%): not reported

Type strain: SKF-I-101055, ATCC 35926, NBRC 14879, JCM 8971.

Sequence accession no. (16S rRNA gene): not available.

3. **Microbispora karnatakensis** Rao, Prabhu, Sridhar, Venkateswarlu and Actor 1987, 184[VP]

kar.na.ta.ken′sis. N.L. fem. adj. *karnatakensis* of or pertaining to the State of Karnataka, India, the source of the soil from which the type strain was isolated.

Substrate mycelia were orange to yellowish brown on most media, and yellowish orange soluble pigments were produced on most media. Oval spores (1.2–1.8 µm). Good growth on glycerol-asparagine agar, but no aerial mycelium, yellowish brown substrate mycelium, no diffusible pigment. Moderate growth on glycerol-asparagine agar +1% yeast extract with orange substrate mycelium and bright yellow diffusible pigment. Good growth on oatmeal agar with white aerial mycelium, brownish-orange substrate mycelium, deep orange-yellow diffusible pigment. Good growth on yeast-extract-malt extract agar with pale pink aerial mycelium, deep orange substrate mycelium, no diffusible pigment. Temperature growth range is 28–50°C.

Casein is degraded and amylase is produced. D-Glucose, L-rhamnose, and *meso*-inositol are used as sole carbon sources, but L-arabinose and glycerol are not.

DNA G+C content (mol%): not available.

Type strain: SKF-I-58261, ATCC 35927, IMSNU 22065, JCM 8972.

Sequence accession no. (16S rRNA gene): AY445647.

Genus V. **Microtetraspora** Thiemann, Pagani and Beretta 1968b, 296[AL] emend. Zhang, Wang and Ruan 1998a, 420[VP]

Martha E. Trujillo and Michael Goodfellow

Mi.cro.te.tra.spo′ra. Gr. adj. *mikros* small; Gr. adj. *tetra* four; Gr. n. *spora* a seed; N.L. fem. n. *Microtetraspora* the small four-spored (organism).

Aerobic, Gram-stain-positive, non-acid–alcohol-fast, nonmotile, mesophilic actinomycetes **which form stable, highly branched substrate and aerial mycelia**. **Spore chains, typically contain four spores which are borne on short aerial hyphae. Spores are spherical (1.2–1.5 µm in diameter) or slightly oval to cylindrical (1.0–1.4 to 1.2–1.7 µm in diameter) and have smooth surfaces**. **Grows from 20–37°C, but not at 40°C**. Some species require B vitamins for growth. Chemoorganotrophic with an oxidative type of metabolism. **Cell walls contain *N*-acetylated muramic acid and major amounts of *meso*-diaminopimelic acid; has a type A1γ peptidoglycan**. Contains complex mixtures of saturated, unsaturated, iso-, anteiso-, and branched chain fatty acids. **Predominant menaquinones have nine isoprene units with hydrogenation at positions III and IV [MK-9(III, IV-H_4)]. Major phospholipids are diphosphatidylglycerol, phosphatidylethanolamine, hydroxyl-phosphatidylethanolamine, and ninhydrin-positive glycophospholipids**. Common in soils.

DNA G+C content (mol%): 69–71.

Type species: **Microtetraspora glauca** Thiemann, Pagani and Beretta 1968b, 296[AL].

Further descriptive information

Phylogeny. The genus *Microtetraspora* contains four species including *Microtetraspora glauca*, *Microtetraspora fusca*, *Microtetraspora malaysiensis*, and *Microtetraspora niveoalba* (Table 282). The type strains of these species form a distinct phyletic line in the *Streptosporangiaceae* 16S rRNA gene tree that is most closely related to the genera *Microbispora* and *Nonomuraea* (Figure 371). The four *Microtetraspora* type strains share 16S rRNA gene similarities within the range 97.9–99.1%. The corresponding DNA–DNA relatedness values range from 21–52% (Nakajima et al., 2003).

Cell morphology. Microtetrasporae form short, sparsely branched aerial hyphae which typically carry chains of four spores (Figure 372, Figure 373, Figure 374, and Figure 375), though chains of two or three spores, and more rarely of five spores, have been reported (Nakajima et al., 2003; Zhang et al., 1998a). Peculiar side branches have been observed on the spore chains of *Microtetraspora niveoalba* (Figure 375). The spores of *Microtetraspora fusca* tend to fuse into a spore mass as the culture ages.

Nutrition and growth conditions. Microtetrasporae are readily cultivated on rich media including modified Bennett's (Jones, 1949), glucose-yeast extract (Gordon and Mihm, 1962), oatmeal (Shirling and Gottlieb, 1966), and yeast extract-malt extract (Shirling and Gottlieb, 1966) agars. *Microtetraspora fusca* and *Microtetraspora glauca* grow well and sporulate on Hickey–Tresner (Hickey and Tresner, 1952) agar. *Microtetraspora malaysiensis* grows well on yeast-malt extract agar (Nakajima et al., 2003). *Microtetraspora niveoalba* requires B vitamins for growth on synthetic media (Nonomura and Ohara, 1971d). Microtetrasporae grow between 20 and 37°C, but not at 40°C.

Cell-wall composition. *Microtetraspora* strains contain *meso*-diaminopimelic acid as the major wall diamino acid (wall

chemotype III *sensu* Lechevalier and Lechevalier, 1970b). The sugar pattern is variable and may be either B (presence of madurose) or C (no characteristic sugar). The wall peptidoglycan contains *N*-acetylated muramic acid (Kawamoto et al., 1981; Nakajima et al., 2003). Microtetrasporae contain major amounts of diphosphatidylglycerol, phosphatidylethanolamine, hydroxylphosphatidylethanolamine, and ninhydrin and sugar positive phospholipids (phospholipid type IV *sensu* Lechevalier et al., 1977), major proportions of tetrahydrogenated menaquinones with nine isoprene units saturated at sites III and VIII, and substantial proportions of MK-9(H_0) and MK-9(H_2) (Kroppenstedt et al., 1990a; Nakajima et al., 2003). Members of the genus contain complex mixtures of fatty acids that include major proportions of 14-methylpentadecanoic ($C_{16:0}$ iso) and 10-methylheptadecanoic ($C_{17:0}$ 10-methyl) acids (Table 283; Miyadoh et al., 1989; Kroppenstedt et al., 1990a; Nakajima et al., 2003).

Ecology. Microtetrasporae are common in soils including forest soils (Hayakawa et al., 1996, 1988; Lazzarini et al., 2000; Nakajima et al., 2003; Nonomura and Ohara, 1971d; Thiemann et al., 1968b). Using humic acid agar, Nonomura and Hayakawa (1988) recorded mean counts of 3.6×10^4 colony-forming units (c.f.u.) per gram dry weight of soil for soil samples collected from forests in Japan. *Microtetraspora niveoalba* strains were particularly widely distributed, albeit with counts $<10^3$ c.f.u./g dry weight soil (Nonomura and Ohara, 1971d). *Microtetraspora malaysiensis* strains have been isolated from two locations on the Malaysian Peninsula, namely from soil taken from a primary lowland dipterocarp forest at Pasok, Negeri Sembilan and from a dipterocarp forest at the Virgin Jungle Reserve, Gombak, Selangor. *Microtetraspora fusca* and *Microtetraspora glauca* have been isolated from soil samples collected in Brazil, Italy, and Thailand.

Enrichment and isolation procedures

Little is known about the activities of microtetrasporae in natural habitats, though members of the *Microtetraspora glauca* group degrade grass lignocellulose and xylan, but not cellulose (Hayakawa et al., 1996). These workers also showed that some members of the taxon show antimicrobial activity. *Microtetraspora fusca*, *Microtetraspora glauca*, and *Microtetraspora malaysiensis* were isolated from soil samples using undisclosed methods (Nakajima et al., 2003; Thiemann et al., 1968b). However, a pretreatment of dry heating air-dried soil samples, developed for the isolation of *Microbispora* and *Streptosporangium* (Nonomura and Ohara, 1969a), has proven useful for isolating most *Microtetraspora* species. Spores of microtetrasporae appear to be especially resistant to the use of dry heat at 100–120°C, a practice which significantly reduces associated actinomycetes and bacteria present in soil and allows the slow-growing *Microtetraspora* strains to develop into recognizable colonies on isolation plates. Microtetrasporae have also been isolated by plating out

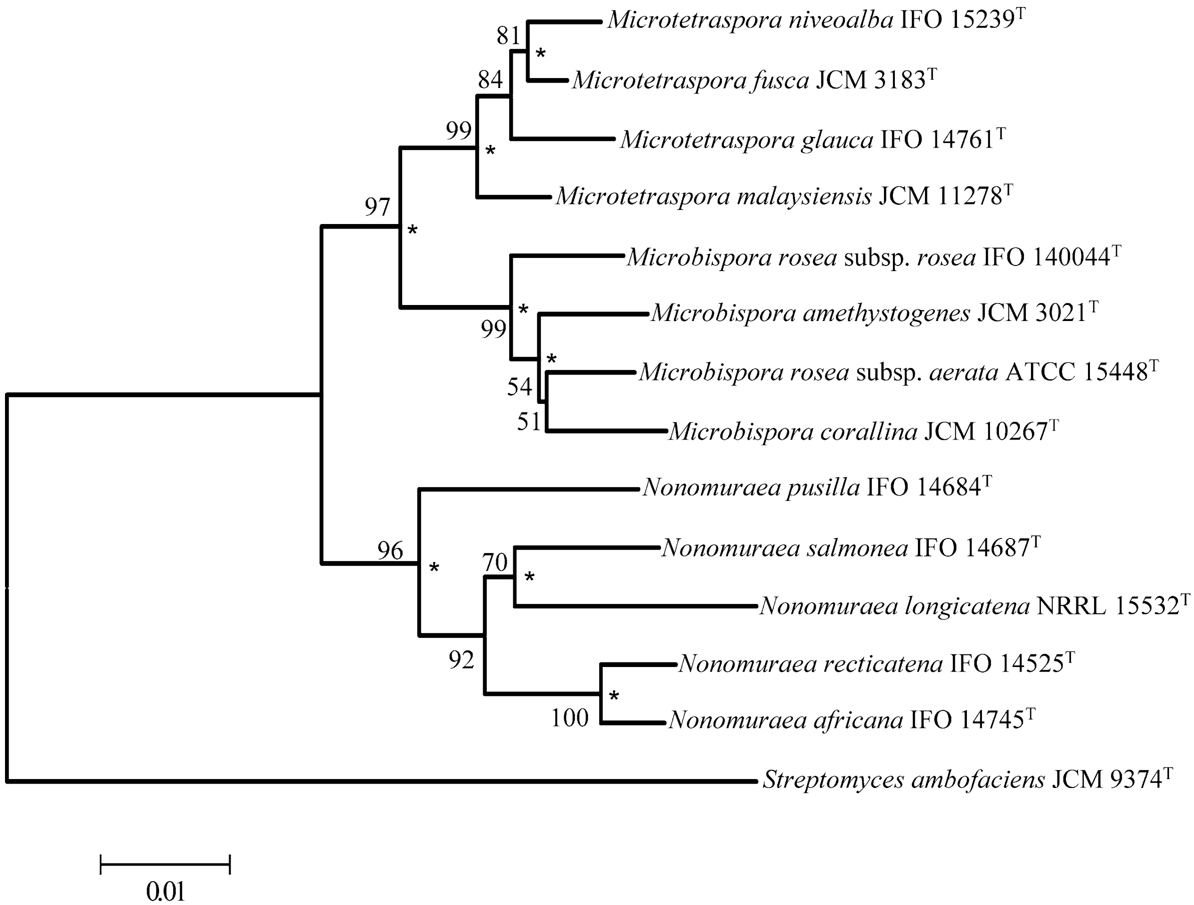

FIGURE 371. Neighbor-joining tree based on 16S rRNA gene sequences showing the phylogenetic relationships between *Microtetraspora* species and selected members of the family *Streptosporangiaceae*. Bootstrap values are shown at branching points. Asterisks indicate that the corresponding nodes were also recovered in maximum parsimony and maximum likelihood trees. *Streptomyces ambofaciens* JCM 9374^T was used as an outgroup. Bar = 1 substitution per 100 nucleotides.

air-dried and heated soil onto isolation media supplemented with antibiotics such as streptomycin and rifamycin (Li, 1989). Li et al. (2002) selectively isolated actinomycetes, including microtetrasporae, from soil using high frequency radiation.

Microtetraspora niveoalba was isolated from soil which had been dry heated at 120°C for 1 h. Particles of soil were sprinkled sparingly on MGA-SE* agar plates (Nonomura, 1989b; Nonomura and Ohara, 1971d) which were incubated at 38–39°C for 1 month. To obtain pure cultures, fragments of visible colonies that appeared on the primary isolation plates were streaked onto MGA-SE agar. *Microtetraspora glauca* strains have been isolated infrequently on MGA-SE agar plates at 30°C, but *Microtetraspora fusca* was not detected, possibly because of the high pH (8.0) of the medium.

Hayakawa et al. (1996) developed a plate culture procedure for the isolation of members of the *Microtetraspora glauca* group (*Microtetraspora glauca*, *Microtetraspora fusca*, and *Microtetraspora niveoalba*) from soils and sediments. Suspensions of soil in water were treated with benzethonium chloride, plated onto LSV-SE agar† supplemented with kanamycin, norfloxacin, and naladixic acid, and incubated at 32°C for 4 weeks. Members of the *Microtetraspora glauca* group formed large, flat colonies covered with white or whitish gray aerial hyphae which differentiated into linear chains of four spores. Members of the *Microtetraspora glauca* group were isolated from 18 out of 26 environmental samples (16 from field and forest soils, 2 from freshwater sediments) and accounted for 2–27% of the total populations recovered on isolation plates.

Maintenance procedures

Sporulated slant cultures can be maintained at 4°C for 3–4 months; suitable media include glycerol-asparagine, Hickey–Tresner, and oatmeal agars. Suspensions of spores and hyphae in glycerol (20%, v/v) can be stored in liquid nitrogen at −80°C. Lyophilization is recommended for long-term preservation; this involves suspending spores and mycelia in a suitable fluid such as serum plus 7.5% (w/v) glucose or skimmed milk plus 7.5% glucose.

Differentiation of the genus *Microtetraspora* from other genera

Microtetraspora strains can be distinguished from the genera *Actinomadura*, *Microbispora*, and *Nonomuraea* by their ability to form characteristic chains of four spores on distinct sporophores.

Taxonomic comments

Four *Microtetraspora* species were included in the last edition of *Bergey's Manual of Systematic Bacteriology* (Nonomura, 1989b), namely *Microtetraspora glauca* Thiemann et al. 1968b, *Microtetraspora fusca* Thiemann et al. 1968b, *Microtetraspora niveoalba* Nonomura and Ohara 1971d, and "*Microtetraspora viridis*" Nonomura and Ohara 1971d. An additional species, "*Microtetraspora caesia*" Tomita et al. 1980 was cited as a *species incertae sedis*. Miyadoh et al. (1989) transferred "*Microtetraspora viridis*" to the genus *Actinomadura* as *Actinomadura viridis*. The genus *Microtetraspora* provided a temporary home for the *Actinomadura pusilla* group (Fischer et al., 1983; Goodfellow et al., 1988; Kroppenstedt et al., 1990a; Poschner et al., 1985) until it became clear that members of this taxon and those belonging to the *Microtetraspora glauca* group can be separated using DNA–DNA relatedness (Miyadoh et al., 1989), fatty acid (Kroppenstedt et al., 1990a; Miyadoh et al., 1989), numerical taxonomic (Athalye et al., 1985; Goodfellow and Pirouz, 1982), electrophoretic

*MGA-SE agar (Nonomura and Ohara, 1971d): asparagine, 1 g; glucose, 2 g; K_2HPO_4, 0.5 g; soil extract, 200 ml; agar, 20 g; cycloheximide, 50 mg; nystatin, 50 mg; benzyl penicillin, 0.8 mg; polymixin B, 4.0 mg: distilled water, 800 ml; pH 8.0. The soil extract was prepared by autoclaving 1000 g of soil in 1000 ml water for 30 min before decanting and filtering.

†LSV-SE agar: commercial lignin, 1 g, soybean flour, 0.2 g., soil extract, 100 ml, $CaC0_3$, 0.02 g., $FeSO_4 \cdot 7H_2O$, 0.01 g;. KCl, 1.7 g, $MgSO_4 \cdot 7H_2O$, 0.05 g; $Na_2 HPO_4$, 0.5 g., B-vitamins (0.5 mg each of *p*-aminobenzoic acid, calcium pantothenate, inositol, niacin, pyridoxine-HCl, riboflavin, thiamine HCl, and 0.25 mg biotin), cycloheximide, 50 mg, kanamycin, 20 mg, naladixic acid, 10 mg, norfloxacin, 20 mg, nystatin, 50 mg., distilled water 1 liter.

[a]Data from Kroppenstedt et al. (1990a), Miyadoh et al. (1989), and Nakijama et al. (2003). Quantitative variation between some of the values may be due to differences in cultivation conditions.

mobility of ribosomal AT-L30 protein (Ochi et al., 1991), and 16S rRNA gene sequence data (Wang et al., 1996b). The *Actinomadura pusilla* group was subsequently classified in a new taxon, the genus *Nonomuraea* Zhang et al. 1998a.

"*Microtetraspora tyrrhenii*" was proposed by Tomita et al. (1991) for an organism which formed hooked or spiral spore chains and had other properties consistent with its classification in the *Actinomadura pusilla* group. This organism probably belongs to the genus *Nonomuraea*, but this proposition cannot be tested as the type strain is no longer extant. *Microtetraspora malaysiensis* was proposed for strains isolated from dipterocarp forest soils (Nakajima et al., 2003).

Differentiation of species of the genus *Microtetraspora*

Microtetraspora species can be distinguished from one another by using a combination of morphological, nutritional and physiological characteristics (Table 282).

List of species of the genus *Microtetraspora*

1. **Microtetraspora glauca** Thiemann, Pagani and Beretta 1968b, 296[AL]

glau′ca. L. fem. adj. *glauca* grayish.

Short aerial hyphae typically contain chains of four spores; occasionally chains with two or three spores are formed and very rarely ones with five spores. Spores are smooth and spherical (1.5 μm) to slightly oval (1.4–1.7 μm) (Figure 372). Good growth on modified Bennett's, Hickey–Tresner, oatmeal, and soil agars. A blue-green to yellowish-green substrate mycelium and a blue-gray aerial spore mass are formed on Hickey–Tresner agar. B vitamins are required for growth. Grows between 20 and 37°C, but not at 40°C. Optimal pH growth range 6.0–7.0.

Produces phosphatases. Hydrogen sulfide is produced. Degrades arbutin, casein, chitin, DNA, esculin, gelatin, and Tweens 20 and 40, and xylan, but not adenine, cellulose, guanine, Tweens 60 or 80, or xanthine. Amygdalin, D-arabinose, cellobiose, glucose, glycogen, maltose, α-methyl-D-

glucoside, ribose, salicin, starch, xylose, sodium acetate, and sodium butyrate are used as sole carbon sources, but adonitol, dulcitol, *meso*-erythritol, ethanol, inulin, lactose, melezitose, raffinose, sorbitol, and sodium propionate are not.

Tolerant (%, w/v) to brilliant green (0.001), crystal violet (0.0001), sodium chloride (3%), and pyronin (0.1), but sensitive to brilliant green (0.01), crystal violet (0.001), lysozyme (0.005), and sodium chloride (5%). Resistant to (μg/ml) demethylchlortetracycline hydrochloride (500), gentamicin sulfate (50), lincomycin hydrochloride (100), novobiocin (50), rifampin (50), streptomycin sulfate (50), and vancomycin hydrochloride (50), but sensitive to cephaloridine hydrochloride (100), kanamycin sulfate (100), neomycin sulfate (50), tobramycin sulfate (50), and penicillin (10 IU) using freeze-dried filter paper discs soaked in antibiotics at appropriate concentrations.

Additional phenotypic properties are shown in Table 282.

Source: soil.

DNA G+C content (mol%): 69 (HPLC).

Type strain: ATCC 23057, DSM 43311, NBRC 14761, JCM 3300, NRRL B-3735, VKM Ac-663.

Sequence accession no. (16S rRNA gene): D85490, U48974, X97891.

2. **Microtetraspora fusca** Thiemann, Pagani and Beretta 1968b, 296[AL]

fus′ca. L. fem. adj. *fusca* dark, tawny.

Aerial spore mass is gray. Substrate mycelium brown-violet on Hickey–Tresner agar. Good sporulation on glucose-asparagine, Hickey–Tresner, glycerol-asparagine, and soil agars, but does not sporulate on oatmeal agar. Grows between 30–37°C, but not at 40°C. Optimal pH for growth range 6.0–7.0.

Arbutin is used as a sole carbon source.

Additional phenotypic properties are shown in Table 282.

Source: soil.

DNA G+C content (mol%): 70 (HPLC).

Type strain: ATCC 23058, DSM 43841, NBRC 13915, JCM 3183, NRRL B-3628, VKM Ac-662.

Sequence accession no. (16S rRNA gene): U48973.

3. **Microtetraspora malaysiensis** Nakajima, Ho and Kudo 2004, 1[VP] (Effective publication Nakajima, Ho and Kudo 2003, 188.)

mal. ay.si. en′sis. N.L. fem. adj. *malaysiensis* of or pertaining to Malaysia, the source of the soil from which the type strain was isolated.

Straight chains of four spores are formed on sporophores branching from aerial hyphae; occasionally chains with two or three spores are formed and rarely ones with five spores. Spores are oval to cylindrical and have smooth surfaces.

Hickey–Tresner agar: moderate growth; aerial mycelium pearl, substrate mycelium old gold, no diffusible pigment. Inorganic salts-starch agar: poor growth; no aerial mycelium, substrate mycelium yellow, no diffusible pigment. Oatmeal agar: moderate growth; aerial mycelium white, substrate mycelium cream, no diffusible pigment. Oatmeal-nitrate agar: moderate growth; aerial mycelium white, substrate mycelium white, no diffusible pigment. Yeast extract-malt extract agar: good growth; aerial mycelium white, substrate mycelium honey gold, no diffusible pigment. Yeast-extract-starch agar: moderate growth; aerial mycelium oyster white, substrate mycelium cream, no diffusible pigment.

Optimum temperature for growth is 25–30°C; does not grow at 40°C.

Degrades casein, DNA, esculin and testosterone, but not adenine, elastin, guanine, keratin, or xylan. Cellobiose, glucose, lactose, maltose, ribose, salicin, starch, and xylose are used as sole carbon sources, but adonitol, arabitol, arbutin, dulcitol, *meso*-erythritol, *meso*-inositol, inulin, melezitose, melibiose, α-methyl-D-glucoside, raffinose, sorbitol, sorbose, and sucrose are not. Sodium citrate is also used as a sole carbon source, but not sodium benzoate, sodium fumarate, sodium lactate, sodium malate, sodium mucate, sodium oxalate, sodium succinate, or sodium tartrate.

Does not grow in the presence of 3% (w/v) NaCl. Thiamine is needed for growth, but requirement for biotin varies. Whole-organism hydrolysates contain glucose, madurose, mannose, and ribose.

Additional phenotypic properties are shown in Table 282.

Source: dipterocarp forest soils on the Malaysian Peninsula.

DNA G+C content (mol%): 69–70 (HPLC).

Type strain: H47–7, DSM 44579, JCM 11278, NBRC 100735.

Sequence accession no. (16S rRNA gene): AB062383.

4. **Microtetraspora niveoalba** Nonomura and Ohara 1971d, 872[AL]

ni.ve.o.al′ba. L. adj. *niveus* snowy; L. adj. *albus* white; N.L. fem. adj. *niveoalba* snow white.

Mesophilic actinomycete that forms a stable, highly branched substrate mycelium. Substrate mycelium pale yellowish brown on Hickey–Tresner agar. The aerial spore mass color is white. Soluble pigments are not produced.

Good sporulation on oatmeal agar, yeast-starch agar, and on glycerol-asparagine agar supplemented with B vitamins. Branched spore chains are present. Growth occurs between 35–40°C. Optimal pH growth range 7.0–8.0. Whole-organism hydrolysates contain madurose.

Additional phenotypic properties are shown in Table 282.

DNA G+C content (mol%): 71 (HPLC).

Type strain: ATCC 27301, DSM 43174, NBRC 15239, JCM 3149.

Sequence accession no. (16S rRNA gene): U48976.

Species *incertae sedis*

1. **Microtetraspora tyrrhenii** Tomita, Oda, Hoshino, Ohkusa and Chikazawa 1992, 191[AL] (Effective publication: Tomita, Oda, Hoshino, Ohkusa and Chikazawa 1991, 945.)

tyr.re′ni-i. L. gen. n. *tyrrenii* (*sic*), of the Tyrrhenian Sea (part of the Mediterranean Sea) which faces the location from which the soil sample was taken and from which the strain was isolated.

Hooked or spiral spore chains (5–15 spores) formed monopodially on the tips of aerial hyphae. The spores (1.2 × 1.6 ~ 2.5 μm) have vertical folds on the surface.

Colonies on yeast extract-malt extract are convex and crateriform.

Glycerol-asparagine agar: moderate growth; aerial mycelium absent, substrate mycelium dark yellow, no diffusible pigment. Inorganic salts-starch agar: poor growth; scant white aerial mycelium, substrate mycelium light olive brown, no diffusible pigment. Oatmeal agar: moderate growth; no aerial mycelium, substrate mycelium light yellow, no diffusible pigment. Peptone-yeast extract-iron agar: moderate growth; no aerial mycelium, substrate mycelium deep yellowish brown, no diffusible pigment. Tyrosine agar: moderate growth; no aerial mycelium, substrate mycelium dark yellow, no diffusible pigment. Yeast extract-malt extract agar: good growth; aerial mycelium white, substrate mycelium deep yellowish brown, no diffusible pigment.

Temperature growth range: 17–40°C. Grows in the presence of NaCl 3% (w/v).

Adenine, casein, esculin, gelatin, hippuric acid, hypoxanthine, and tyrosine are degraded, but xanthine is not. Amylase is produced. Adonitol, D- and L-arabinose, cellobiose, fructose, galactose, glucose, glycerol, *meso*-inositol, lactose, mannitol, mannose, melibiose, raffinose, rhamnose, ribose, salicin, sucrose, trehalose, and xylose are used as sole carbon sources, but dulcitol, *meso*-erythritol, melezitose, sorbitol, and D-sorbose are not.

DNA G+C content (mol%): not determined.

Type species: Q464-31, ATCC 53931.

2. **"Microtetraspora caesia"** Tomita, Hoshino, Sasahira, Hasegawa and Akiyama 1980

Forms single, pairs or chains of three to eight spores on the aerial mycelium.

Aerial mass color is grayish blue-green. The cell wall contains *meso*-diaminopimelic acid and galactose.

Type strain: E864-61.

Genus VI. **Nonomuraea** corrig. Zhang, Wang and Ruan 1998b, 419[VP]

Peter Kämpfer

No.no.mu.ra′e.a. N.L. fem. n. *Nonomurea* named after Hideo Nonomura, a Japanese taxonomist who has made many contributions to the biology of actinomycetes.

Aerobic, Gram-stain-positive, non-acid-fast bacteria that form **extensively branched substrate and aerial mycelia.** Aerial mycelia bear chains of spores which are hooked, spiral, or straight. The spore surface can be folded, irregular, smooth, or warty. Growth temperature ranges from 20–45°C, in some cases up to 55°C. **Cell walls contain *meso*-diaminopimelic and whole-cell hydrolysates contain madurose as the diagnostic sugar. Contains diphosphatidylglycerol, phosphatidylethanolamine, hydroxylated phosphatidylethanolamine, and ninhydrin and sugar positive phospholipids as predominant phospholipids.. Major menaquinones are MK-9(H_4), MK-9(H_2), and MK-9(H_0).** Major types of fatty acids are C_{17} 10-methyl and C_{16} iso-branched fatty acids.

DNA G+C content (mol%): 64–73.

Type species: **Nonomuraea pusilla** corrig. (Nonomura and Ohara 1971a) Zhang, Wang and Ruan 1998b, 419 (*Actinomadura pusilla* Nonomura and Ohara 1971a, 909).

Further descriptive information

The genus *Nonomuria* (*sic*) was proposed by Zhang et al. (1998b) for species which had been classified in the genus *Actinomadura* (Athalye et al., 1985; Fischer et al., 1983; Poschner et al., 1985) prior to their reclassification to the genus *Microtetraspora* (Kroppenstedt et al., 1990a). Chiba et al. (1999), who pointed out that the name *Nonomuria* (*sic*) was a misnomer according to the *Bacteriological Code* (1990 Revision) (Rule 57a, Appendix 9), introduced the name *Nonomuraea* as the correct spelling of the genus. On the basis of 16S rRNA gene sequence data, this group belongs to the family *Streptosporangiaceae* (Goodfellow et al., 1990b; Goodfellow and Quintana, 2005; Stackebrandt et al., 1997; Zhang et al., 1998b). Interestingly, Goodfellow et al. (1988) were the first to propose the genus *Nonomuria* to accommodate species of the *Actinomadura pusilla* group, but this proposition was not formally published. The taxon encompasses 24 species and 2 subspecies with validly published names. Representatives of each of these validly named species form a distinct line in the 16S rRNA *Streptosporangiaceae* gene tree (Goodfellow and Quintana, 2005; Figure 376). The majority of the species previously assigned to the *Actinomadura pusilla* group, and now part of the genus *Nonomuraea*, originated from soil (Galatenko et al., 1981; Meyer, 1979; Nonomura and Ohara, 1971b).

Only a few reports have been published about the genetics and metabolism of members of the genus despite their potential importance, notably in the discovery of novel bioactive compounds. The gene cluster encoding the biosynthesis of glycopeptide antibiotic A40926 in *Nonomuraea* strain ATCC 39727 has been isolated and characterized by Sosio et al. (2003). This glycopeptide, which is a member of the teichoplanin family of glycopeptides, is the precursor of dalbavancin. Sosio and her colleagues also isolated the novel compound dechloromannosyl-A40926 aglycone following the construction of a *Nonomuraea* mutation by deleting the *dbr* open reading frames 8–10. Subsequently, Alduina et al. (2005) constructed a bacterial artificial chromosomal library of *Nonomuraea* ATCC 39727 using an *Escherichia coli–Streptomyces* artificial chromosome (ESAC) and screened for the presence of dbv genes known to be involved in the biosynthesis of glycopeptide A40926. The heterologous expression of *Nonomuraea* genes in *Streptomyces lividans* was successfully demonstrated by using combined RT-PCR and proteomic approaches. These

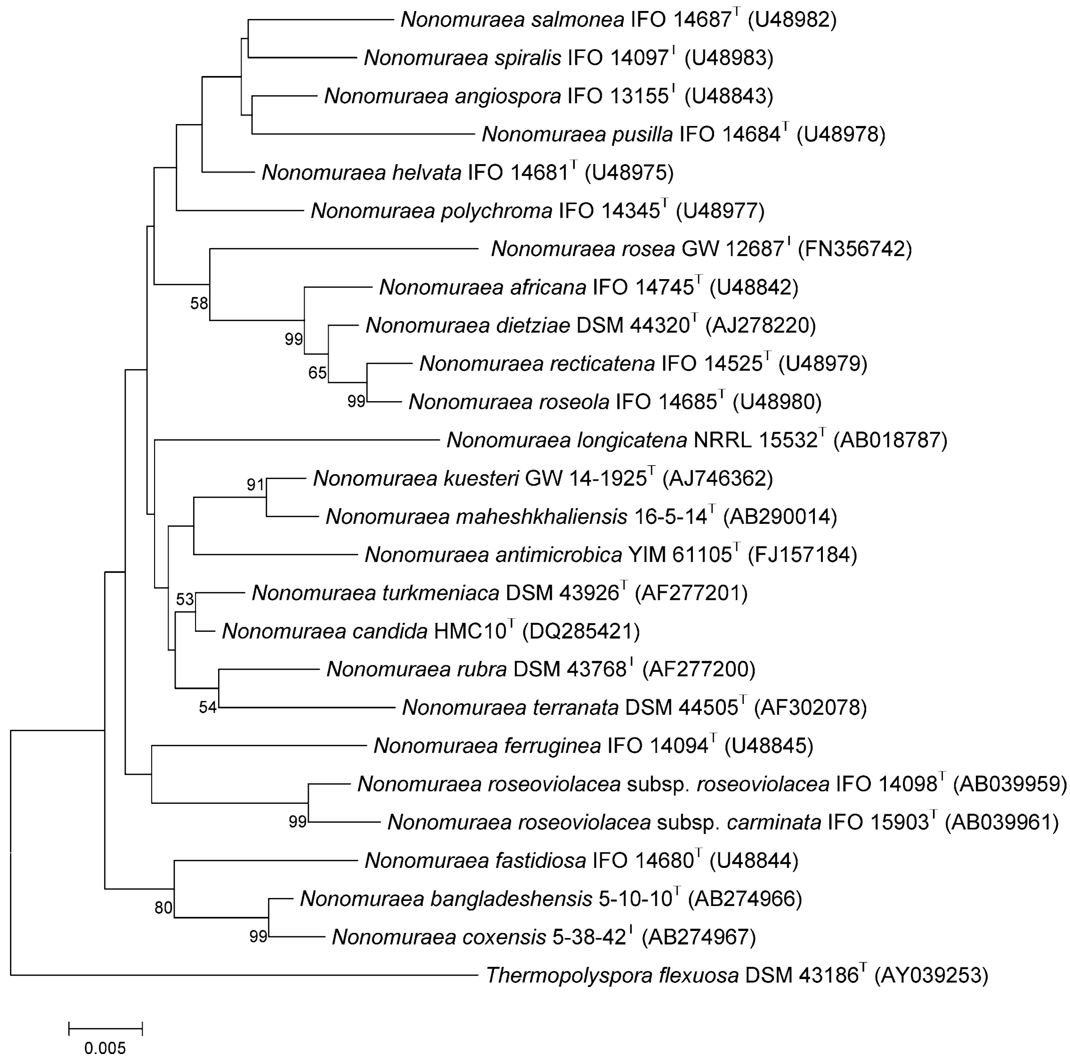

FIGURE 376. Phylogenetic analysis of *Nonomuraea* based on 16S rRNA gene sequences available from the European Molecular Biology Laboratory data library (accession numbers are given in brackets) constructed after multiple alignment of data (distance options according to the Kimura-2 model) and clustering with the neighbor joining method. Bootstrap values based on 1000 replications are listed as percentages at the branching points. Bar = 0.05 nucleotide substitutions per nucleotide position.

results indicate that *Streptomyces lividans* may be a good host for the genetic analysis of *Nonomuraea* strains. It was also demonstrated that *Nonomuraea* ATCC 39727 has a special carbon metabolism. Glucose is primarily metabolized via the Entner–Doudoroff pathway, even though the energetically more favorable Embden–Meyerhof–Parnas pathway is present in this organism (Gunnarsson et al., 2003). In addition, *Nonomuraea* utilizes a PP_i-dependent phosphofructokinase, an enzyme that has been connected with anaerobic metabolism in eukaryotes and higher plants but which has been recognized recently in several actinomycetes. Beltrametti et al. (2004, 2003) showed that the catabolism products of branched chain amino acids provide biosynthetic precursors for the formation of several lipid-containing antibiotics. The effect of valine on the production of glycopeptide antibiotic A40926 was studied in detail. The addition of valine to a minimal medium had a positive effect on the production of A40926; similar results were obtained in a rich production medium.

Members of the family *Streptosporangiaceae*, including *Nonomuraea* species, are an increasingly rich source of commercial products, notably antibiotics and enzymes (Goodfellow and Quintana, 2005). *Nonomuraea rosea* has been shown to produce deoxycephalomycin B (Okazaki and Naito, 1985), *Nonomuraea roseoviolacea* produces carminomicins (Nakagawa et al., 1983, 1989), *Nonomuraea rubra* produces maduromycin (Fleck et al., 1978), *Nonomuraea pusilla* produces actinotiocin (Tamura

et al., 1973), and *Nonomuraea spiralis* produces pyralomicin (Naganawa et al., 2002).

Enrichment and isolation procedures

Goodfellow and Quintana (2005) reported that dry heat treatment of air-dried soil samples and dilution plate culture with selective synthetic media is useful for the preferential isolation and enumeration of some members of the family *Streptosporangiaceae*, including members of the genera *Microtetraspora* and *Nonomuraea* (Nonomura and Ohara, 1971b, 1971c, 1971d). In addition, Nonomura and Hayakawa (1988) reported that pretreatment of soil suspensions with yeast extract (6%, w/v) and sodium dodecylsulfate (0.05%, w/v) at 40°C for 20 min, followed by dilution with water, activates actinomycete spores but kills vegetative cells of other soil bacteria in the suspensions, thereby leading to an increase in the counts of actinomycetes on isolation plates.

An improved procedure for the selective isolation of streptosporangiae from soil was reported by Hayakawa et al. (1991a). The method is based on the ability of streptosporangial spores to withstand dry heat and treatment with benzethonium chloride (BC) and the capacity of streptosporangiae to grow in the presence of leukomycin and nalidixic acid. Initially, an air-dried soil sample is ground in a mortar and heated in a hot-air oven for an hour; 0.5 ml of a 10^{-1} dilution in water of the heated sample is transferred to 4.5 ml of sterile 5 mM phosphate buffer (pH 7.0) containing BC at a final concentration of 0.1% (w/v). The resultant preparation is maintained at 30°C for 30 min with occasional stirring, and a portion (1 ml) is then diluted with sterile tap water (1:10 or 1:15). Inocula of 0.1 ml or 0.2 ml of the dilution is then spread over the surface of plates of HV agar supplemented with leukomycin in ethanol (1 mg/l) and nalidixic acid (20 mg/l) and the plates incubated at 30°C for 3–4 weeks. Actinomycetes which appear on the plates are examined by light microscopy (× 600) and assigned to genera on the basis of characteristic morphological properties. This pretreatment procedure has been used to isolate several *Nonomuraea* species including *Nonomuraea helvata*, *Nonomuraea pusilla*, *Nonomuraea roseoviolacea*, and *Nonomuraea spadix* (Nonomura and Ohara, 1971b).

Nonomuraea spores appear to be particularly resistant to dry heat at 100–120°C, thereby allowing the slow-growing nonomuraea to develop into recognizable colonies on dilution plates. Soil dilutions are plated onto various media including AV and MGA-SE agars, and incubated for several weeks at 28–30°C (Nonomura and Ohara, 1971d) (Methods taken from Goodfellow and Quintana, 2005.). Other *Nonomuraea* species such as *Nonomuraea salmonea* and *Nonomuraea roseola* have been isolated from soil on media supplemented with antibiotics. Lavrova et al. (1972) added rubomycin (5, 10, or 20 μg/ml) to medium no. 2 of Gauze et al. (1957); Preobrazhenskaya et al. (1975a) added bruneomycin (0.5, 1, or 2 μg/ml) or streptomycin (0.5, 1, or 2 μg/ml). The use of these antibiotics led to the growth of more *Nonomuraea* colonies on isolation plates while reducing the number of streptomycetes. In contrast, *Nonomuraea ferruginea* and *Nonomuraea spiralis* were isolated by plating soil suspensions onto oatmeal agar or Gauze's no. 1 medium without addition of selective antibiotics (Meyer, 1979).

Nonomuraea species also grow well on rich media including modified Bennett's (Jones, 1949), glucose-yeast extract (Waksman, 1950b), nutrient (BBL), oatmeal (ISP medium 3; Difco 0771), TS (BBL) and yeast extract-malt extract agars [ISP medium 2 (Difco 0770); Shirling and Gottlieb, 1966] as well as on PYES medium (Altenburgera et al., 1996). Most investigators recommend oatmeal-yeast extract agar for the growth of mesophilic strains and glycerol agar for thermophilic strains (Nonomura, 1989c).

Maintenance procedures

Goodfellow and Quintana (2005) reported that the most convenient method for short-term storage is by serial transfer from agar slants of complex media every 2 months (Meyer, 1989); tubes should be tightly closed with cotton plugs dipped in melted paraffin wax. Sporulated spore cultures can be stored at 5°C and at room temperature. Lyophilization, storage in liquid nitrogen, and freezing in glycerol can be used for long-term preservation (Goodfellow and Quintana, 2005; Meyer, 1989). *Nonomuraea* cultures may be lyophilized by procedures commonly used for bacteria. For lyophilization, the spore suspension or vegetative mycelium is suspended in a suitable fluid such as serum plus 7.5% (w/v) glucose or skimmed milk plus 7.5% (w/v) glucose. For storage in liquid nitrogen, the microorganisms are inoculated into small test tubes containing the appropriate medium and incubated until satisfactory growth is visible. Glycerol suspensions are prepared by scraping aerial growth or substrate mycelium or both from heavily inoculated plates and making heavy suspensions in 3 ml of aqueous glycerol in small (e.g. bijoux) bottles, which are stored at −20°C.

Differentiation of the genus *Nonomuraea* from other genera

Despite some differences, members of the family *Streptosporangiaceae* are chemically homogeneous but morphologically diverse (Table 284). *Nonomuraea* strains are distinguished from members of related genera by their ability to form chains of spores or pseudovesicles on aerial hyphae. The species may be distinguished by means of spore chain morphology, spore wall ornamentation, color of mature sporulated aerial mycelium, and substrate mycelium pigmentation. Nevertheless, identification of most species is difficult because, in many instances, only one (the type) or a few strains have been examined. In addition, *Nonomuraea* may be distinguished from other genera in the family *Streptosporangiaceae* by slight differences in cell-wall peptidoglycan, menaquinone type, colony pigmentation, the G+C content of the DNA, and growth at low temperatures (Table 284).

TABLE 284. Chemotaxonomic, morphological, and physiological characteristics of the genera classified in the family *Streptosporangiaceae*[a,b]

Characteristic	*Nonomuraea*	*Acrocarpospora*	*Herbidospora*	*Microbispora*	*Microtetraspora*	*Planobispora*	*Planomonospora*	*Planotetraspora*	*Streptosporangium*	*Thermopolyspora*

[a]Symbols: +, present; –, absent; nd, not determined.

[b]Data were taken from this and previous studies (Goodfellow et al., 1990b; Goodfellow and Quintana, 2005; Greiner-Mai et al., 1987; Kudo et al., 1993; Stackebrandt et al., 2001; Tamura and Sakane, 2004; Tamura et al., 2000).

[c]The major constituents of the cell wall are alanine, glutamic acid, glucosamine, and *meso*-A_2pm (Lechevalier and Lechevalier, 1970a). Diagnostic phospholipid type: II: only phosphatidylethanolamine; IV: glucosamine (with phosphatidylethanolamine and phosphatidylmethylethanolamine variable) (Lechevalier et al., 1977).

[d]Abbreviations exemplified by MK-9(H_4), menaquinone having four of the nine isoprene units hydrogenated.

[e]Whole-organism sugar patterns of actinomycetes containing *meso*-A_2pm: A, arabinose and galactose; B, madurose; C, no diagnostic sugar; D, arabinose and xylose (Lechevalier and Lechevalier, 1970b).

List of species of the genus *Nonomuraea*

1. **Nonomuraea pusilla** corrig. (Nonomura and Ohara 1971a) Zhang, Wang and Ruan 1998b, 419 (*Actinomadura pusilla* Nonomura and Ohara 1971a, 909)

pu.sil′la. L. fem. adj. *pusilla* dwarfish, referring to the aerial mycelium of the organism.

Spore chains in tightly closed spirals forming so-called pseudosporangia, i.e. spores are embedded in a slimy mass (Figure 377). Pseudosporangia are 3–6 μm in diameter. Spore surface smooth.

Glycerol-asparagine agar: good growth, aerial mycelium white, substrate mycelium grayish pink, no diffusible pigment. Inorganic salts-starch agar: scant growth, aerial mycelium microscopically visible, substrate mycelium colorless to brownish, no diffusible pigment. Inorganic salts-starch agar: scant growth, aerial mycelium microscopically visible, substrate mycelium colorless to brownish, no diffusible pigment. Oatmeal agar: abundant growth, surface farinaceous, aerial mycelium white to cream colored, substrate mycelium pale grayish brown, no diffusible pigment. Oatmeal salts-starch agar: good growth, surface granular to farcinoceus, aerial mycelium white, substrate mycelium colorless to white, no diffusible pigment. Yeast extract-malt extract agar: good growth, surface cartilaginous, aerial mycelium only microscopically visible, substrate mycelium dark brown with a red tinge, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, mannose, and ribose. Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids and hydroxylated phosphatidylethanolamine are present. Traces of phosphatidylinositol are found, but phosphatidylglycerol, phosphatidylinostol mannosides, and uncharacterized glycolipids are absent.

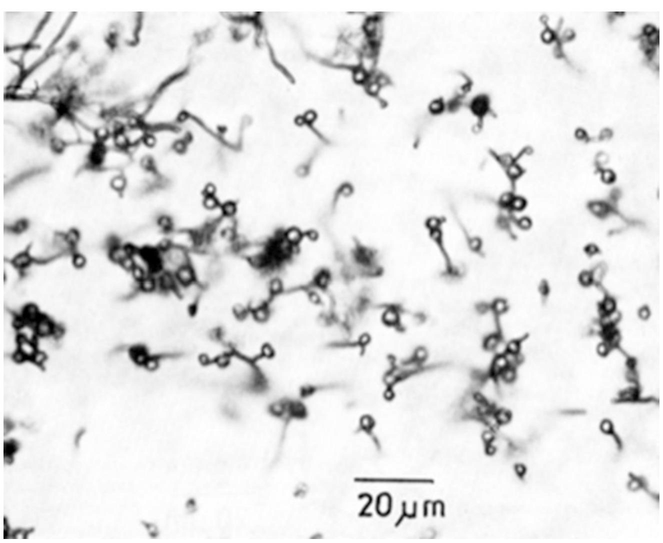

FIGURE 377. *Nonomuraea pusilla*, type strain ATCC 27296. Sporulating aerial mycelium with "pseudosporangia". Grown on yeast extract–malt agar at 28°C for 9 d.

Further chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin hydrolysis and nitrate reductase tests are positive. Degrades DNA, gelatin, hypoxanthine, and tyrosine. Positive for acetoin, arginine dihydrolase, gelatinase, and urease activities. Further physiological characteristics are given in Table 286. Does not utilize L-arabinose, D-cellobiose, D-fructose, *meso*-inositol, D-mannose, L-rhamnose, or D-xylose as sole carbon sources.

Source: soil.

DNA G+C content (mol%): 68.3 (T_m).

Type strain: ATCC 27296, CBS 262.72, BCRC 11619, CECT 3284, CIP 106954, DSM 43357, NBRC 14684, IMET 9586, JCM 3144, KCTC 9278, NCIMB 11116, NRRL B-16126, VKM Ac-1508.

Sequence accession no. (16S rRNA gene): D85491, U48978.

Additional comments: Nonomuraea pusilla can be easily mistaken for a *Streptosporangium* on superficial microscopic examination; it can only be differentiated by exact proof of a sporangial wall, which indicates a *Streptosporangium* strain. Tamura et al. (1973) isolated a sulfur-containing peptide antibiotic, actinotiocin, from *Nonomuraea pusilla*.

2. **Nonomuraea africana** corrig. (Preobrazhenskaya and Sveshnikova 1974) Zhang, Wang and Ruan 1998b, 419[VP] (*Actinomadura africana* Preobrazhenskaya and Sveshnikova 1974, 865; *Nocardiopsis africana* Preobrazhenskaya and Sveshnikova 1985, 224; *Microtetraspora africana* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

a.fri.ca′na. L. fem. adj. *africana* referring to Africa, the source of the soil sample.

Straight spore chains with 4–10 spores per chain. Spore ornamentation smooth. Growth of aerial mycelium on oatmeal agar is grayish blue, substrate mycelium growth is yellow, and the soluble pigment color yellowish brown.

Esculin is hydrolyzed and nitrate reduced. Casein, DNA, gelatin, hypoxanthine, starch, and tyrosine are degraded. Cell hydrolysates contain madurose. Diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, phosphatidylinositol mannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present.

Further chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is given in Table 285.

L-Arabinose, cellobiose, fructose, mannose, *meso*-inositol, raffinose, rhamnose, sucrose, and xylose are utilized and used as sole carbon sources. Positive for acetoin, arginine dihydrolase, citrate lyase, β-galactosidase, dihydrolase, gelatinase, lysine decarboxylase, ornithine decarboxylase, and urease activities.

Further physiological characteristics are given in Table 286.

DNA G+C content (mol%): 64.0 (T_m).

Type strain: ATCC 35107, DSM 43748, NBRC 14745, INA 1839, JCM 6240, KCTC 9260, NRRL B-16114, RIA 1839, VKM Ac-924.

Sequence accession no. (16S rRNA gene): AJ269555, U48842.

[d]Data from Ara et al. 2007a).

[e]Data from Kämpfer et al. (2010).

3. **Nonomuraea angiospora** corrig. (Zhukova, Tsyganov and Morozov 1968) Zhang, Wang and Ruan 1998b, 419^{VP} (*Micropolyspora angiospora* Zhukova, Tsyganov and Morozov 1968, 728; *Microtetraspora angiospora* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

an.gi.o.spo′ra. Gr. neut. n. *angeion* (L. translit. *angium*) vessel; Gr. n. *spora* a spore; N.L. n. *angiospora* spores enclosed (in capsules).

Spore chains (2–15 spores) are curved or irregularly coiled. Spores spherical to oval (1.5–2.4 × 1.2–2.2 μm); surface spines enveloped in a translucent capsule. White aerial mycelium is formed on soya flour and oatmeal agars; substrate mycelium and colonies white to deep flesh or ochre colored. Grows between 21 and 37°C, and optimally at 27°C.

Cell hydrolysates contain madurose, ribose, and traces of mannose. Diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol mannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present. Phosphatidylethanolamine and phosphatidylinositol are absent.

Further chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin is hydrolyzed; nitrate is not reduced. Positive for acetoin, arginine dihydrolase, gelatinase, and urease activities. Degrades DNA, gelatin, hypoxanthine, and tyrosine. Does not use L-arabinose, cellobiose, D-fructose, *meso*-inositol, D-mannose, D-raffinose, L-rhamnose, sucrose, or D-xylose as sole carbon sources.

Further physiological characteristics are given in Table 286.

DNA G+C content (mol%): not determined.

Type strain: LIA 3479-30, AS 4.1229, BCRC 13334, DSM 43173, NBRC 13155, JCM 3109, KCTC 9191, KCTC 9261, NRRL B-3905.

Sequence accession no. (16S rRNA gene): U48843.

4. **Nonomuraea antimicrobica** Qin, Zhao, Klenk, Li, Zhu, Xu and Li 2009, 2750^{VP}

an.ti.mi.cro′bi.ca. Gr. prep. *anti* against; N.L.n. *microbium* microbe; L.adj.suff. *-icus -a -um* suffix used with various meanings; N.L.fem.adj. *antimicrobica* antimicrobial.

Gram-stain-positive, aerobic, non-acid-fast, and non-acid–alcohol-fast actinomycete that forms extensively branched, brown substrate mycelia and white-to-pink aerial mycelia on ISP 2–5 and PDA media. After 14 d of incubation at 28°C, spiral spore chains composed of smooth spores are observed on the aerial mycelium. Temperature range for growth is 15–37°C with optimal growth on 28°C. pH range for growth is 6.0–9.0 with optimal growth at 7.0. No growth is observed with 5% NaCl.

Positive for catalase. Negative for oxidase, milk coagulation, milk peptonization, gelatin liquefaction, cellulose, and starch hydrolysis, H_2S production and nitrate reduction. The diagnostic amino acid of the peptidoglycan is *meso*-diaminopimelic acid. Cell hydrolysates contain ribose, glucose, madurose, and galactose. Polar lipids include diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol and phosphatidylinositol mannosides, and the diagnostic phospholipids of phosphatidylethanolamine and an unknown glucosamine-containing phospholipid.

The predominant menaquinone of the type strain is MK-9(H_4); MK-9(H_2), MK-9(H_6), and MK-9 are also present. Major fatty acids (>10%) are $C_{16:0}$ iso, $C_{17:0}$ 10 methyl, $C_{16:1}$ iso G, and $C_{16:0}$.

Source: a surface-sterilized leaf of *Maytenus austroyunnanensis* from the tropical rainforest of Xishuangbanna, Yunnan Province, south-west China.

DNA G+C content (mol%): 69.2 (HPLC).

Type strain: YIM 61105, DSM 45220, CCTCC AA 208016.

Sequence accession no. (16S rRNA gene): FJ157184.

5. **Nonomuraea bangladeshensis** Ara, Kudo, Matsumoto, Takahashi and Ōmura 2007b, 1506^{VP}

ban.gla.desh.en′sis. N.L. fem. adj. *bangladeshensis* of or pertaining to Bangladesh, where the strain was isolated.

Forms a well-developed, branched substrate mycelium. Abundant aerial mycelium is present.

Spore chains are spiral with 1 or 2 turns (8–12 spores). Sporangia are not detected. Spores are spherical to cylindrical, and the spore sheath surface is smooth.

Good growth occurs on Bennett's agar, glucose-yeast extract agar, Hickey–Tresner agar, oatmeal agar (ISP-3), oatmeal-nitrate agar, Seino (yeast-starch) agar, tyrosine agar (ISP-7), Waksman agar, and yeast extract-malt extract agar (ISP-2). Moderate growth is found on glycerol-asparagine agar, inorganic salts-starch agar (ISP-4), nutrient agar, and water agar. Poor growth occurs with glucose-asparagine agar and sucrose-nitrate agar. The color of the substrate mycelium is shell to cinnamon brown on various media.

Pale brown aerial mycelium and sporulation occur on ISP-7 agar, ISP-2 agar, ISP-3 agar, oatmeal-nitrate agar, and water agar media after 14 d incubation at 28°C. A soluble pigment is not produced. Aerobic, Gram-stain-positive, and able to grow at pH 5.0–9.0. The temperature range for growth is between 15 and 45°C. No production of melanoid pigments. No growth is observed at 5% NaCl.

The diagnostic diamino acid isomer of the cell-wall peptidoglycan is *meso*-DAP.

Galactose, glucose, madurose, mannose, and ribose are present in whole-cell hydrolysates.

The *N-acyl*-type of the muramic acid is acetyl. Mycolic acids are absent. The polar lipids include PE and OH-PE. Phosphatidylcholine is absent.

The major menaquinone is MK-9(H_4), with minor amounts of MK-9(H_6), MK-9(H_2), and MK-9(H_0). Major fatty acids are $C_{16:0}$ iso (26.4%), $C_{15:0}$ iso (14.7%), and $C_{17:0}$ 10 methyl (10.5%).

Source: sandy soil from Cox's Bazar, Bangladesh.

DNA G+C content (mol%): 72.7 (HPLC).

Type strain: 5-10-10, JCM 13930, MTCC 8089.

Sequence accession no. (16S rRNA gene): AB274966.

6. **Nonomuraea candida** Le Roes and Meyers 2009, 1^{VP} (Effective publication: Le Roes and Meyers 2008, 136.)

can´di.da. L. fem. adj. *candida* shining white; pertaining to the light coloring of the substrate and aerial mycelial mass when grown on oatmeal agar (IPS-3).

Gram-stain-positive, non-acid-fast, and non-acid–alcohol-fast actinomycete that forms a leathery, dark brown growth on ISP-2 agar. Tan-colored growth is observed on inorganic salts-starch agar (ISP-4); a yellow diffusible pigment is produced on glycerol-asparagine agar (ISP-5) and beige-colored substrate mycelium and white aerial mycelium is visible. No melanin production is observed on peptone-yeast extract-iron agar (ISP-6) and tyrosine agar (ISP-7). Good growth is observed on ISP-2 agar. Weak antibiosis is exhibited against *Mycobacterium aurum* A+ in agar overlays. Bioautographic analysis of organic solvent extracts of the cell mass shows weak antibiosis against *Mycobacterium aurum* A+, but no activity against *Mycobacterium tuberculosis* H37Rv^{T} (=ATCC 27294^{T}).

Growth is observed at 30°C, 37°C, and 45°C, but not at pH 4.3 and 4°C.

The type strain HMC10^{T} is catalase positive and oxidase negative. It grows in the presence of 0.3% 2-phenylethanol, 3% NaCl, and 0.1% phenol, but not in the presence of 0.01% NaN_3. Growth is observed in the presence of cephaloridine (100 μg/ml) (weak), lincomycin (100 μg/ml), oleandomycin (100 μg/ml), penicillin G (10 i.u./ml), rifampin (50 μg/ml), tobramycin (50 μg/ml) (weak), and vancomycin (50 μg/ml) (weak), but not in the presence of gentamicin (100 μg/ml), kanamycin (100 μg/ml), neomycin (50 μg/ml), and streptomycin (100 μg/ml).

Utilizes DL-α-amino-*n*-butyric acid, L-arginine, L-histidine, L-4-hydroxyproline, L-methionine, L-phenylalanine, potassium nitrate, L-serine, and L-valine as sole nitrogen sources, but not L-casteine. Adonitol, D(−) fructose, D(+) galactose, D(+) glucose, *meso*-inositol, inulin, D(−) lactose, D(−) mannose, D(+) melibiose, raffinose, L(+) rhamnose, D(−) ribose, salicin, sodium acetate (0.1%), sucrose, trehalose, and D(+) xylose are utilized as sole carbon sources. L(+) Arabinose, D(+) cellobiose, D(+) melezitose, and xylitol are weakly utilized, but sodium citrate (0.1%) is not utilized as a sole carbon source. Nitrate is not reduced, but H_2S production occurs. Lecithinase, lipase, and protease activity is observed on egg yolk agar. Hippurate and pectin are hydrolyzed. Degrades adenine, esculin, arbutin, casein, and Tween 80. Gelatin is weakly degraded, while allantoin, guanine, hypoxanthine, starch, L-tyrosine, urea, xanthine, and xylan are not degraded.

Source: South African soil.

DNA G+C content (mol%): 72.7 (HPLC).

Type strain: HMC10, DSM 45086, NRRL B-24552.

Sequence accession no. (16S rRNA gene): DQ285421.

7. **Nonomureae coxensis** Ara, Kudo, Matsumoto, Takahashi and Ōmura 2007b, 1507^{VP}

cox.en′sis. N.L. fem. adj. *coxensis* of or pertaining to Cox's Bazar, Bangladesh, the origin of the soil where the type strain was isolated.

Forms a well-developed, branched substrate mycelium. Abundant aerial mycelium is present.

Spore chains are spiral to hooked with 12–17 spores. Sporangia are not detected. Spores are spherical to oval and the spore surface is smooth.

Good growth on Bennett's agar, glucose-yeast extract agar, Hickey–Tresner agar, oatmeal agar (ISP3), oatmeal-nitrate agar, Seino (yeast-starch) agar, 1/5 yeast-starch agar, Waksman agar, and yeast extract-malt extract agar (ISP2). Moderate growth on inorganic salts-starch agar (ISP4), nutrient agar, and tyrosine agar (ISP7); poor growth on glucose-asparagine agar, glycerol-asparagine agar, and water agar.

Substrate mycelium is light melon yellow to apricot (orange-brown) on various agar media. Pale pink to white aerial mycelium and sporulation occur on ISP-2 agar, ISP-3 agar, Bennett's agar, Hickey–Tresner agar, and 1/5 yeast-starch agar media after 14 d incubation at 28°C. A soluble pigment is not produced. Aerobic; Gram-stain-positive.

Growth occurs at pH 5.0–9.0. The temperature range for growth is between 15 and 45°C.

No production of melanoid pigments. No growth on 4% NaCl. The diagnostic diamino acid isomer of the cell-wall peptidoglycan is *meso*-DAP. Galactose, glucose, madurose, mannose, and ribose are present in whole-cell hydrolysates. The *N*-acyl type of muramic acid is acetyl. Mycolic acids are absent. The polar lipids include PE and OH-PE. Phosphatidylcholine is absent. The major menaquinones are MK-9(H_6) and MK-9(H_4). The fatty acid profile is characterized by the presence of significant amounts of $C_{16:0}$ (17.4%), $C_{17:1}$ ω8c (11.5%), and $C_{17:0}$ 10 methyl (8.4%).

Source: sandy soil from Cox's Bazar, Bangladesh.

DNA G+C content (mol%): 72.3 (HPLC).

Type strain: 5-38-42, JCM 13931, MTCC 8090.

Sequence accession no. (16S rRNA gene): AB274967, AB505224.

8. **Nonomuraea dietziae** Stackebrandt, Wink, Steiner and Kroppenstedt 2001, 1439^{VP}

di.et.zi´a.e. N.L. gen. fem. n. *dietziae* of Dietz, named in honor of the American microbiologist Alma Dietz.

Long spore chains, each containing up to 30 spores, formed on aerial mycelium. Spore chains may be stalked or may form clusters emerging directly from the agar. Sporangia are not detected. Irregular spore chains with spirals of 1–2; sometimes 3–5 turns are seen.

Aerial mycelium develops different colors depending upon the ISP medium used: red-brown (yeast extract malt extract agar, ISP2); white, beige, or pink (oatmeal agar, ISP3); pink (inorganic salts starch agar, ISP4 and tyrosine agar, ISP7); antique rose (glycerol-asparagine agar, ISP5); and white (peptone-yeast extract iron agar, ISP6); after approximately 14 d. Depending upon the ISP medium used, the nonfragmenting substrate mycelium is brown (ISP2), beige (ISP3), pink (ISP3, ISP 7), or rose (ISP5, ISP6) in color. Soluble pigments not produced.

Cell hydrolysates contain galactose, glucose, and ribose, but not arabinose or xylose; madurose occurs in minor amounts. Diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; Phosphatidylglycerol and phosphatidylinositol mannosides are absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Qin et al. (2009), Kämpfer et al. (2010).

Positive for acetoin, arginine dihydrolase, β-galactosidase, citrate lyase, gelatinase, ornithine decarboxylase, and urease activities. D-Fructose and L-rhamnose are utilized as sole carbon sources, but cellobiose, *meso*-inositol, D-mannose, D-rhamnose, sucrose, and D-xylose are not. Utilization of L-arabinose is weak.

Further physiological characteristics are given in Table 286.

Shows no antibacterial effect on *Micrococcus luteus*, *Streptococcus murinus*, *Bacillus subtilis*, *Staphylococcus aureus*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Saccharomyces cerevisiae*, *Aspergillus niger*, or *Candida albicans*.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: ATCC 35861, CIP 107127, DSM 44320, NBRC 14309, JCM 3338, NRRL 11111.

Sequence accession no. (16S rRNA gene): AB006156, AJ278220, AJ294350.

9. **Nonomuraea fastidiosa** corrig. (Soina, Sokolov and Agre 1975) Zhang, Wang and Ruan 1998b, 419[VP] (*Actinomadura fastidiosa* Soina, Sokolov and Agre 1975, 883; *Microtetraspora fastidiosa* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

fas.ti.di.o′sa. L. fem. adj. *fastidiosa* fastidious, referring to the difficulties in growing the organism.

Spore chains consist of irregular spirals of 1–2, more rarely 3–4, turns arranged monopodially on long aerial hyphae (Figure 378). Spore surface ornamentation smooth or slightly irregular. Temperature range: 23–55°C, optimum temperature 30–45°C.

Inorganic salts-starch agar (Gauze 1 medium): moderate growth, aerial mycelium sparse and cream colored to pinkish, substrate mycelium colorless, no diffusible pigment. Oatmeal agar: good growth, surface farinaceous, aerial mycelium white to pale pink, substrate mycelium colorless or pale brownish, no diffusible pigment. Yeast extract-malt extract agar: moderate growth, surface granular with spots of whitish aerial mycelium at the edges of colonies, substrate mycelium pale brown, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, mannose, and ribose. Diphosphatidylglycerol, phosphatidylethanolamine, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; traces of phosphatidylinositol and ninhydrin and sugar positive phospholipids are also found, but phosphatidylglycerol and phosphatidylinositol mannosides are absent.

Further chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Positive for acetoin, arginine dihydrolase, citrate lyase, β-galactosidase, gelatinase, lysine decarboxylase, ornithine decarboxylase, and urease activities. L-Arabinose, citrate fructose, glucose, and rhamnose are utilized as sole carbon sources, but cellobiose, mannose, *meso*-inositol, rhamnose, sucrose, and xylose are not.

Further physiological characteristics are given in Table 286.

DNA G+C content (mol%): 67 (T_m).

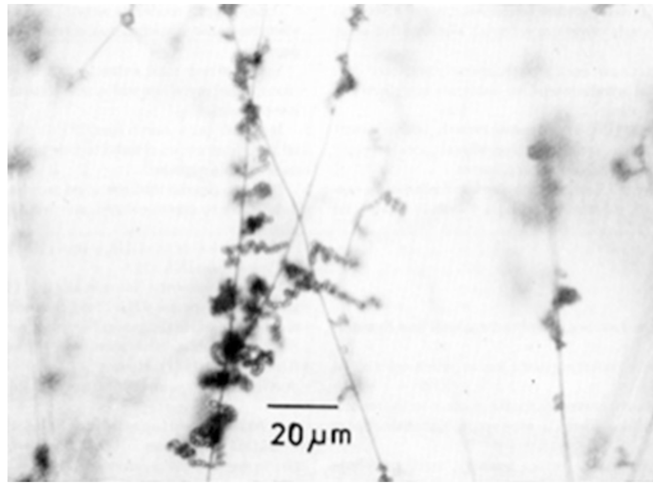

FIGURE 378. *Nonomuraea fastidiosa* strain IMET 9614. Sporulating aerial mycelium. Grown on oatmeal agar at 28°C for 21 d.

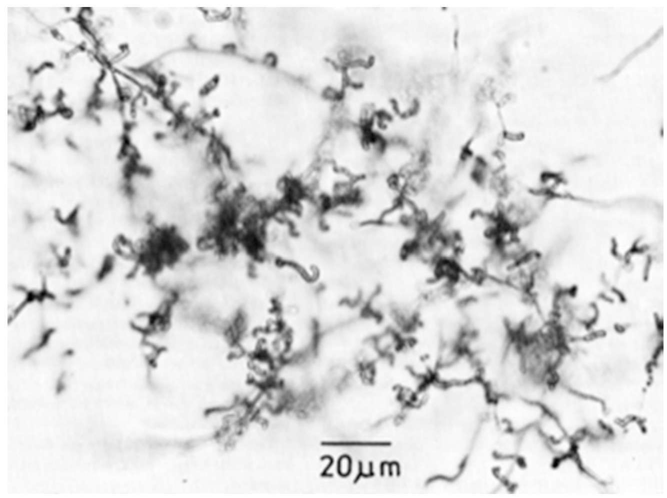

FIGURE 379. *Nonomuraea ferruginea*, type strain IMET 9567. Sporulating aerial mycelium. Grown on oatmeal agar at 28°C for 18 d.

Type strain: ATCC 33516, BCRC 12546, DSM 43674, NBRC 14680, INMI 104, JCM 3321, KCTC 9268, VKM Ac-804.

Sequence accession no. (16S rRNA gene): U48844.

10. **Nonomuraea ferruginea** corrig. (Meyer 1981) Zhang, Wang and Ruan 1998b, 419[VP] (*Actinomadura ferruginea* Meyer 1981, 215; *Microtetraspora ferruginea* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

fer.ru.gi′ne.a. L. fem. adj. *ferruginea* rusty brown, referring to the orange-brown-colored substrate mycelium.

Spore chains short, hooked, or irregular spirals of 1–2 turns, arranged monopodially on long aerial hyphae, 4–9 spores per chain (Figure 379). Spore surface smooth or irregularly folded. Optimum temperature: 28–30°C.

Inorganic salts-starch agar: poor growth, surface leathery, aerial mycelium absent, substrate mycelium color-

less to brownish, no diffusible pigment. Oatmeal agar: growth abundant, surface farinaceous, aerial mycelium white to pale pink, substrate mycelium pink, no diffusible pigment. Oatmeal-nitrate agar: growth abundant, surface dusty, aerial mycelium white to pale pink, substrate mycelium orange-pink, no diffusible pigment. Peptone-glucose medium: growth moderate, surface cartilaginous, aerial mycelium absent, substrate mycelium light brown, no diffusible pigment. Yeast extract-malt extract agar: growth abundant, surface farinaceous, aerial mycelium orange-pink, substrate mycelium bright orange-brown, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, and ribose. Diphosphatidylglycerol, phosphatidylinositolmannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; phosphatidylethanolamine, phosphatidylglycerol, and phosphatidylinositol are absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Positive for arginine dihydroloase, acetoin, citrate lyase, β-galactosidase, gelatinase, lysine decarboxylase, ornithine decarboxylase, and urease activities. L-Arabinose, D-fructose, D-mannose, L-rhamnose, sucrose, and D-xylose are utilized as sole carbon sources, but cellobiose, *meso*-inositol, and D-raffinose are not.

DNA G+C content (mol%): 68.1 (T_m).

Type strain: 14094, ATCC 35575, CCM 3424, BCRC 12537, CIP 106925, DSM 43553, NBRC 14094, IMET 9567, JCM 3283, KCTC 9269, NCIMB 11630, NRRL B-16096, VKM Ac-854.

Sequence accession no. (16S rRNA gene): U48845.

11. **Nonomureae helvata** corrig. (Nonomura and Ohara 1971a) Zhang, Wang and Ruan 1998b, 419[VP] (*Actinomadura helvata* Nonomura and Ohara 1971a, 904; *Microtetraspora ferruginea* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

hel.va′ta. N.L. fem. adj. *helvata* honey-yellow, referring to the color of the substrate mycelium.

Spore chains with spirals of 3–5 turns are seen, or hooks and pseudosporangia on long aerial hyphae. About 10 spores per chain. Spore surface smooth.

Inorganic salts-starch agar: moderate growth, surface farinaceous, aerial mycelium white to cream colored, substrate mycelium yellowish brown, no diffusible pigment. Oatmeal agar: moderate growth, surface leathery, aerial mycelium a filmy cover of sterile hyphae, substrate mycelium yellowish brown, no diffusible pigment. Oatmeal-nitrate agar: good growth, surface farinaceous, aerial mycelium white, substrate mycelium cream colored, no diffusible pigment. According to Nonomura and Ohara (1971a), B vitamins are essential for growth. Yeast extract-malt extract agar: good growth, surface farinaceous, aerial mycelium yellowish white, substrate mycelium yellowish brown, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, ribose, and traces of mannose. Diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositolmannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; phosphatidylethanolamine and phosphatidylinositol are absent. Esculin is hydrolyzed. Shows arginine dihydrolase, β-galactosidase, gelatinase, lysine decarboxylase, ornithine decarboxylase, and urease activities, but does degrade casein, gelatin, hypoxynthine, starch, tyrosine, or xanthine. Cellobiose, *meso*-inositol, sucrose, and D-xylose are utilized as sole carbon sources.

Further physiological characteristics are given in Table 286.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

DNA G+C content (mol%): not determined.

Type strain: ATCC 27295, CBS 259.72, BCRC 13402, DSM 43142, NBRC 14681, IMET 9584, JCM 3143, KCTC 9274, NCIMB 11115, NRRL B-16123, PCM 2199.

Sequence accession no. (16S rRNA gene): U48975.

12. **Nonomuraea kuesteri** Kämpfer, Kroppenstedt and Grün-Wollny 2005, 848[VP]

ku.es´te.ri. N.L. gen. masc. n. *kuesteri* of Küster, in honor of Eberhard Küster, a German microbiologist, in recognition of his numerous contributions to the taxonomy of actinomycetes.

Spiral spore chains with 3–5 turns. Spore ornamentation not determined. Yellow substrate mycelium, a trace of aerial mycelium, but no soluble pigments formed on oatmeal agar.

Cell hydrolysates contains madurose. Diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, phosphatidylinositolmannosides, ninhydrin-and sugar-positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Does not produce acid from adonitol, L-arabinose, arabitol, cellobiose, dulcitol, erythritol, glucose, *meso*-inositol, lactose, maltose, D-mannitol, melibiose, methyl D-glucoside, raffinose, L-rhamnose, salicin, sorbitol, sucrose, trehalose, and D-xylose. *N*-Acetyl-D-glucosamine, adonitol, L-aspartate (weak), L-arabinose, D-cellobiose, fumarate (weak), D-fructose, D-galactose, D-glucose, DL-lactate, malate, D-mannitol, D-mannose, D-melibiose, 2-oxoglutarate, L-proline, L-rhamnose, sucrose, D-trehalose, and D-xylose are used as sole carbon sources after 7 d, but acetate, *N*-acetyl-D-galactosamine, *cis*-aconitate, *trans*-aconitate, adipate, 4-aminobutyrate, L-alanine, β-alanine, *p*-arbutin, azelate, citrate, D-gluconate, glutarate, L-histidine, DL-3-hydroxybenzoate, DL-4-hydroxybenzotae, DL-3-hydroxybutyrate, itaconate, *meso*-inositol, L-leucine, maltitol, D-maltose, mesaconate, L-ornithine, L-phenylalanine, L-phenylacetate, putrescine, propionate, pyruvate, D-ribose, salicin, L-serine, sorbitol, suberate, and L-tryptophan are not.

Further physiological characteristics are given in Table 286.

DNA G+C content (mol%): not determined.

Type strain: GW 14-1925, DSM 44753, JCM 13854, NRRL B-24325.

Sequence accession no. (16S rRNA gene): AJ746362.

13. **Nonomuraea longicatena** Chiba, Suzuki and Ando 1999, 1628[VP]

lon.gi.ca.te′na. L. adj. *longus* long; L. n. *catena* chain; N.L. n. *longicatena* long chain, referring to long spore chains.

Straight spore chains with 10–30 spores per chain. Spore ornamentation smooth. No growth at 45°C.

Oatmeal agar: substrate mycelium growth is ochre, white aerial mycelium, no soluble pigment. Yeast extract-malt extract agar: abundant growth, ochre substrate mycelium, white aerial mycelium.

Cell hydrolysates contain madurose. Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin is hydrolyzed; nitrate is not reduced. Degrades casein, elastin, hypoxanthine, and starch.

L-Arabinose, D-mannose, and D-raffinose are utilized as sole carbon sources, but cellobiose, *meso*-inositol, and L-rhamnose are not. Positive for arginine dihydrolase, β-galactosidase, lysine decarboxylase, ornithine decarboxylase, and urease activities. Production of gelatinase is negative; Grows in the presence of up to 3% NaCl.

DNA G+C content (mol%): 71.7 (HPLC).

Type strain: K-252, NBRC 16462, JCM 11136, NRRL 15532.

Sequence accession no. (16S rRNA gene): AB018787.

14. **Nonomuraea maheshkhaliensis** Ara, Kudo, Matsumoto, Takahashi and Ōmura 2007c, 2449[VP] (Effective publication: Ara, Kudo, Matsumoto, Takahashi and Ōmura 2007a, 164.)

ma.hesh.kha.li.en.sis. N.L. fem adj. *maheshkhaliensis* of or pertaining to Maheshkhali, Bangladesh.

Forms a well-developed, branched substrate mycelium. Abundant aerial mycelia are present. Spore chains are spiral with 2–4 turns (17–20 spores). Sporangia are not detected. Spores are spherical to cylindrical and spore surface is folded and rough.

Good growth occurs on Bennett's agar, glucose-yeast extract agar, Hickey–Tresner agar, oatmeal agar (ISP3), oatmeal-nitrate agar, Waksman no. 1 agar, and yeast extract-malt extract agar (ISP2); moderate growth on glycerol-asparagine agar, inorganic salts-starch agar (ISP4), nutrient agar, sucrose-nitrate agar, tyrosine agar (ISP-7) water agar, and yeast extract-malt extract agar; poor growth on glucose-asparagine agar.

Substrate mycelium color is mustard to light wheat color on various agar media.

White aerial mycelia and sporulation occur on ISP3, ISP4 agar, oatmeal-nitrate agar and water agar after 14 d of incubation at 28°C.

A soluble pigment is not produced. Aerobic, Gram-stain-positive, and able to grow at pH 5.0–9.0.

The temperature range for growth is between 15 and 37°C. Production of melanoid pigments is negative. No growth on 4% NaCl.

The isomer of A_2pm was *meso* and galactose, glucose, madurose, mannose, ribose (trace) in the whole-cell hydrolysates. The *N*-acyl type of muramic acid is acetyl. Mycolic acids are absent. The polar lipids include phosphatidylethanolamine and phospholipids of unknown structure containing glucosamine. Phosphatidylcholine is absent.

The menaquinone is MK-9(H_4). Fatty acids with major amounts of $C_{16:0}$ (15.5%), $C_{16:0}$ iso (13.8%), and $C_{17:0}$ 10 methyl (9.6%).

Source: mangrove rhizosphere soil in Maheshkhali, Bangladesh.

DNA G+C content (mol%): 72.0 (HPLC).

Type strain: 16-5-14, JCM 13929, MTCC 8545.

Sequence accession no. (16S rRNA gene): AB290014.

15. **Nonomuraea polychroma** corrig. (Galatenko, Terekhova and Preobrazhenskaya 1981) Zhang, Wang and Ruan 1998b, 419[VP] (*Actinomadura polychroma* Galatenko, Terekhova and Preobrazhenskaya 1981, 803; *Microtetraspora polychroma* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

po.ly.chro′ma. Gr. adj. *polus* many; Gr. n. *chroma* color; N.L. n. *polychroma* intended to mean that the bacterium produces many colors (Note: the epithet *polychroma* is not correct, however, it is not possible to correct it.)

Short spore chains are produced in the form of spirals or pseudosporangia. Spore surface smooth.

Colorless to brown substrate mycelium, traces of white aerial mycelium, but no diffusible pigments formed on oatmeal agar.

The cultures of this species have no antagonistic activity with respect to various test-microbes.

Cell hydrolysates contain madurose and mannose. Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present, as are traces of phosphatidylinositolmannosides.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Does not use L-arabinose, cellobiose, fructose, *meso*-inositol, mannose, raffinose rhamnose, sucrose, or D-xylose as sole carbon sources. Esculin is hydrolyzed, nitrate is not reduced. Elastin, gelatin, and hypoxanthine are degraded. Acetoin, arginine dihydrolase, lysine decarboxylase, and ornithine decarboxylase activities are positive.

DNA G+C content (mol%): not determined.

Type strain: ATCC 49500, DSM 43925, NBRC 14345, IMET 9743, INA 2755, JCM 6834, KCTC 9277, NRRL B-16243, VKM Ac-1084.

Sequence accession no. (16S rRNA gene): U48977.

16. **Nonomuraea recticatena** corrig. (Gauze, Terekhova, Galatenko, Preobrazbenskaya, Borisova and Fedorova 1984) Zhang, Wang and Ruan 1998b (*Actinomadura recticatena* Gauze, Terekhova, Galatenko, Preobrazbenskaya,

Borisova and Fedorova 1984, 3; *Microtetraspora recticatena* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

rec.ti.ca.te′na. L. part. adj. *rectus* straight; L. n. *catena* a chain; N.L. n. *recticatena* (nominative in apposition), a straight chain.

Straight chains of 4–20 spores. Spore ornamentation smooth. The aerial mycelium develops white to cream color on oatmeal agar; substrate mycelium growth is dark yellow to brown; no soluble pigment found.

Cell hydrolysates contain galactose and traces of ribose. Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, uncharacterized glycolipids, and traces of phosphatidylinositol are present; phosphatidylglycerol and phosphatidylinostol mannosides are absent.

Further chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Positive for esculin hydrolysis and nitrate reductase. Degrades elastin, gelatin, hypoxanthine, and starch. Positive for acetoin and urease activities. Arginine dihydrolase, citrate lyase, β-galactosidase, lysine decarboxylase, and ornithine decarboxylase are not produced. Further physiological characteristics are given in Table 286. L-Arabinose, *meso*-inositol, and L-rhamnose used as sole carbon sources but cellobiose, D-fructose, D-mannose, D- raffinose, sucrose, and D-xylose are not.

DNA G+C content (mol%): not determined.

Type strain: DSM 43937, NBRC 14525, INA 308, JCM 6835, KCTC 9279, VKM Ac-940.

Sequence accession no. (16S rRNA gene): AJ404230, U48979.

17. **Nonomuraea rosea** Kämpfer, Busse, Tindall, Nimtz and Grün-Wollny 2010, 1123[VP]

ro.se′a. L. fem. adj. *rosea* rose-colored or rosy, referring to the pinkish color of the colonies.

Forms an extensive branched substrate mycelium. A white aerial mycelium is visible on oatmeal agar. Spore chains are spiral; sporangia are not detected. Gram-stain-positive and oxidase positive; shows oxidative metabolism.

Good growth occurs after 3 d incubation on oatmeal agar and nutrient agar (Oxoid) at 25–30°C.

The polar lipids include the major compound diphosphatidylglycerol, moderate amounts of phosphatidylmonomethylethanolamine, phosphatidylethanolamine, hydroxy-phosphatidylethanolamine, hydroxy-phosphatidylmonomethylamine, and an unknown aminophosphoglycolipid. Phosphatidylinositol-mannosides and phosphatidylinositol are present along with small amounts of an unknown phospholipid.

Does not produce acids from the following carbon sources: glucose, lactose, sucrose, D-mannitol, dulcitol, salicin, adonitol, inositol, sorbitol, L-arabinose, raffinose, L-rhamnose, maltose, D-xylose, trehalose, cellobiose, methyl D-glucoside, erythritol, melibiose, and arabitol. The following carbon sources are utilized (after 7 d incubation): *N*-acetyl-D-galactosamine, *N*-acetyl-D-glucosamine, D-cellobiose, D-fructose, D-galactose, D-glucose, D-maltose, D-mannose, L-rhamnose, D-trehalose, D-xylose, adonitol, inositol, 4-aminobutyrate, citrate, fumarate (weak), DL-malate, L-aspartate (weak), and L-proline. The following carbon sources are not utilized: *p*-arbutin, D-gluconate, D-melibiose, D-ribose, sucrose, salicin, maltitol, D-mannitol, sorbitol, putrescine, acetate, propionate, *cis*-aconitate, *trans*-aconitate, adipate, azelate, glutarate, DL-3-hydroxybutyrate, itaconate, mesaconate, pyruvate, DL-lactate, suberate, 2-oxoglutarate, L-alanine, β-alanine, L-histidine, L-leucine, L-ornithine, L-phenylalanine, L-serine, L-tryptophan, DL-3-hydroxybenzoate, DL-4-hydroxybenzoate, and L-phenylacetate.

The fatty acids comprise mainly iso- and 10-heptadecanoic-branched fatty acids. Smaller amounts of unsaturated fatty acids are also detected.

Source: a soil sample.

DNA G+C content(mol%): not determined.

Type strain: GW 12687, CCUG 56107, DSM 45177.

Sequence accession no. (16S rRNA gene): FN356742.

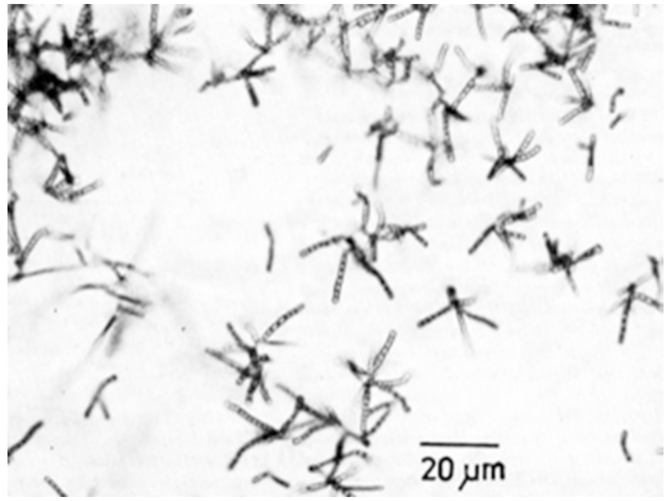

FIGURE 380. *Nonomuraea roseola*, type strain INA 1671. Sporulating aerial mycelium. Grown on oatmeal-nitrate agar at 28°C for 12 d.

18. **Nonomuraea roseola** corrig. (Lavrova and Preobrazhenskaia 1975) Zhang, Wang and Ruan 1998b, 420[VP] (*Actinomadura roseola* Lavrova and Preobrazhenskaya 1975, 483; *Microtetraspora roseola* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

ro.se.o′la. L. adj. *roseus* rose-colored; L. fem. suff. *-ola* diminutive ending; N.L. fem. dim. adj. *roseola* intended to mean with a rosy tinge, referring to the rose-colored aerial mycelium.

Spore chains with spirals of 3–5 turns, or straight chains with 6–30 spores per chain. Spore chains may be stalked or in clusters emerging directly from the agar (Figure 380). Spores elliptical. Spore surface folded.

Czapek sucrose agar: good growth, surface farinaceous, aerial mycelium white, substrate mycelium colorless, no diffusible pigment. Glycerol-asparagine agar: good growth, surface farinaceous, aerial mycelium white to pale pink, substrate mycelium pink to orange colored, no diffusible pigment. Oatmeal agar: abundant growth, surface farinaceous, aerial mycelium pink, substrate mycelium brownish red, no diffusible pigment. Peptone-glucose medium:

good growth, surface leathery, aerial mycelium absent, substrate mycelium yellow to orange colored, no diffusible pigment. Yeast extract-malt extract agar: abundant growth, surface farinaceous, aerial mycelium pink, substrate mycelium rusty brown, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, and ribose; variable for mannose. Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present, as are traces of phosphatidylglycerol; phosphatidylinositol and phosphatidylinositolmannosides are absent.

Additional chemotaxonomic date are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin is hydrolyzed and nitrate reduced. Degrades gelatin, hypoxanthine, and tyrosine. Positive for arginine dihydrolase, citrate lyase, β-galactosidase, lysine decarboxylase, ornithine decarboxylase, and urease. *meso*-Inositol, L-rhamnose and sucrose are utilized as sole carbon source, but L-arabinose, cellobiose, D-fructose, D-mannose, D-raffinose, and D-xylose are not.

Additional physiological characteristics are given in Table 286.

DNA G+C content (mol%): 66.2 (T_m).

Type strain: ATCC 33579, DSM 43767, NBRC 14685, IMET 9576, INA 1671, JCM 3323, KCTC 9282, VKM Ac-1180.

Sequence accession no. (16S rRNA gene): AJ278221, U48980.

19. **Nonomuraea roseoviolacea** (Nonomura and Ohara 1971a) *Nonomuria roseoviolacea* Zhang, Wang and Ruan 1998b, 420[VP] (*Actinomadura roseoviolacea* Nonomura and Ohara 1971a, 909; *Microtetraspora roseviolacea* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

ro.se.o.vi.o.la′ce.a. L. adj. *roseus* rosy; L. adj. *violaceus* violet colored; N.L. fem. adj. *roseoviolacea* rosy, violet colored, referring to the color of the substrate mycelium (Note: the epithet *roseoviolacea* is not correct, however, it is not possible to correct it.).

Pseudosporangia spore chains with 4–20 spores per chain. Spore ornamentation smooth.

Glucose-asparagine agar: moderate growth, surface slightly farinaceous on the edge of the colonies, substrate mycelium brownish red, pale violet diffusible pigment. Glycerol-asparagine agar: good growth, surface leathery, aerial mycelium absent, substrate mycelium brick red, no diffusible pigment. Inorganic salts-starch agar: good growth, surface farinaceous, aerial mycelium white, substrate mycelium white to pale pink, no diffusible pigment. Oatmeal agar: good growth, surface farinaceous, aerial mycelium pale pink to violet, substrate mycelium pale violet, pale violet diffusible pigment. Yeast extract-malt extract agar: good growth, surface farinaceous to granular, aerial mycelium white to pale pink, substrate mycelium dark purple, no diffusible pigment.

Cell hydrolysates contain madurose, mannose, and ribose. Diphosphatidylglycerol, phosphatidylinositolmannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; phosphatidylethanolamine, phosphatidylglycerol, and phosphatidylinositol are absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin hydrolyzed and nitrate reduced; DNA and hypoxanthine are degraded. L-Arabinose, D-fructose, D-mannose, D-raffinose, L-rhamnose and sucrose, are utilized as sole carbon sources, but cellobiose is not. Positive for acetoin, arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and urease activities, but negative for β-galactosidase activity.

DNA G+C content (mol%): 68.5 (T_m).

Type strain: AS 4.1072, ATCC 27297, CBS 260.72, CCM 3491, BCRC 13406, CIP 106924, DSM 43144, NBRC 14098, IMET 9751, JCM 3145, KCTC 9283, NCIMB 11117, NRRL B-16127, VKM Ac-909.

Sequence accession no. (16S rRNA gene): AB039959, AB043101.

Additional comments: in their original description, Nonomura and Ohara (1971a) reported on antibacterial activity of the type strain against *Staphylococcus aureus*. Further investigation of this strain (J. Meyer, unpublished) revealed an active agent similar to daunomycin.

19a. **Nonomuraea roseoviolacea subsp. roseoviolacea** (Nonomura and Ohara 1971a) *Nonomuria roseoviolacea* Zhang, Wang and Ruan 1998b, 420[VP] (*Actinomadura roseoviolacea* Nonomura and Ohara 1971a, 909; *Microtetraspora roseviolacea* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

The original description of *Nonomuraea roseoviolacea* subsp. *roseoviolacea* given by Nonomura and Ohara (1971a) is unchanged. In addition, this subspecies shows reduction of nitrate and liquefies gelatin. Sucrose is not utilized as a sole carbon source. DNA–DNA similarity to *Nonomuraea roseoviolacea* subsp. *carminata* ranges from 49–60%.

DNA G+C content (mol%): 68.5 (T_m).

Type strain: AS 4.1072, ATCC 27297, CBS 260.72, CCM 3491, BCRC 13406, CIP 106924, DSM 43144, NBRC 14098, IMET 9751, JCM 3145, KCTC 9283, NCIMB 11117, NRRL B-16127, VKM Ac-909.

Sequence accession no. (16S rRNA gene): AB039959, AB043101.

19b. **Nonomuraea roseoviolacea subsp. carminata** (Gauze, Sveshnikova, Ukholina, Gavrilina, Filicheva and Gladkikh 1973) Gyobu and Miyadoh 2001, 887[VP] (*Actinomadura carminata* Gauze, Sveshnikova, Ukholina, Gavrilina, Filicheva and Gladkikh 1973, 675)

car.mi.na′ta. N.L. fem. adj. *carminata* (from Fr. *carmin*), carmine.

Substrate hyphae are long, irregularly branched, and do not fragment into short elements. Aerial hyphae branch monopodially and are 0.3–0.4 μm in diameter. Spore chains are formed on the aerial hyphae in tightly closed spirals. Well-developed spore chains are enveloped in a slimy mass, giving the appearance of sporangia (pseudosporangia). Spores are oval to cylindrical in shape and 0.6–1.2 μm in size, with smooth surfaces.

A pink aerial hyphal mass, and a wine-red soluble pigment is formed on yeast-extract–malt extract agar.

Starch is hydrolyzed. Grows at 42°C. Reduction of nitrate, liquefaction of gelatin, peptonization of milk, and production of melanoid pigments are negative. Grows in the presence of 3% NaCl. L-Arabinose, D-fructose, D-galactose D-glucose, L-rhamnose, sucrose, and D-xylose are used as sole carbon sources, but *meso*-inositol, D-mannitol and raffinose are not.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: DSM 44170, NBRC 15903, INA 4281, JCM 9946, VKM Ac-1780.

Sequence accession no. (16S rRNA gene): AB039961.

20. **Nonomuraea rubra** corrig. (Sveshnikova, Maksimova and Kudrina 1969) Zhang, Wang and Ruan 1998b, 420^{VP} (*Micromonospora rubra* Sveshnikova, Maksimova and Kudrina 1969, 883; *Actinomadura rubra* Meyer and Sveshnikova 1974, 167)

ru′bra. L. fem. adj. *rubra* red-colored, referring to the color of substrate mycelium.

Spore chains with 4–20 spores per chain form curled hooks, spirals with 1–2 turns or spirals with 3–5 turns. Spore ornamentation smooth. Sporulating aerial mycelium mostly seen only in microscopically visible traces after 4–6 weeks of incubation on oatmeal agar, oatmeal-nitrate agar, and Bennett sucrose agar.

Bennett's sucrose agar: good growth, surface cartilaginous or wrinkled, aerial mycelium only traces and pinkish gray, substrate mycelium red to orange, red diffusible pigment. Oatmeal agar: good growth, surface wrinkled, aerial mycelium very poorly developed and mostly sterile or coremia-like, substrate mycelium bright orange-red, pale red diffusible pigment. Oatmeal-nitrate agar: moderate growth, surface cartilaginous glistening, aerial mycelium only traces and pinkish-gray, substrate mycelium red to orange, no diffusible pigment. Yeast extract-malt extract agar: moderate growth, surface cartilaginous glistening, aerial mycelium only traces of sterile hyphae, substrate mycelium dark red to brown, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, ribose, and traces of mannose. The cell-wall composition of *Nonomuraea rubra* shows a slight difference from type III/B of Lechevalier and Lechevalier (1970b). In addition to *meso*-A_2pm, minor amounts of L-A_2pm and glycine have been found.

Diphosphatidylglycerol, phosphatidylinositol, phosphatidylinositol mannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; Phosphatidylethanolamine and phosphatidylglycerol are absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Nitrate is reduced but esculin is not hydrolyzed. Degrades elastin, gelatin, hypoxanthine, starch, and tyrosine. Positive for acetoin, arginine dihydrolase, citrate lyase, β-galactosidase, gelatinase, lysine decarboxylase, ornithine decarboxylase, and urease activities. L-Arabinose, cellobiose, D-fructose, *meso*-inositol, D-mannose, D-raffinose, L-rhamnose, sucrose, and xylose are utilized as sole carbon sources.

Produces the antibiotic maduramycin, a red pigment with indicator properties (pH <7.0 yellow, pH >7.0 red) which possesses a strong antimicrobial activity against Gram-stain-positive bacteria (Fleck et al., 1978).

DNA G+C content (mol%): not determined.

Type strain: ATCC 27031, CBS 132.76, BCRC 12591, CIP 107008, DSM 43768, NBRC 14070, NBRC 14686, IMET 8181, INA 325, JCM 3234, JCM 3389, KCTC 9284, NRRL B-16083, VKM Ac-615.

Sequence accession no. (16S rRNA gene): AF277200.

21. **Nonomuraea salmonea** corrig. (Preobrazhenskaya, Lavrova, Ukholina and Nechaeva 1975b) Zhang, Wang and Ruan 1998b, 420^{VP} (*Actinomadura salmonea* Preobrazhenskaya, Lavrova, Ukholina and Nechaeva 1975b, 408; *Microtetraspora salmonea* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

sal.mo′ne.a. N.L. fem. adj. *salmonea* from L. n. *salmo* salmon, salmon colored referring to the color of substrate mycelium.

Spore chains with 4–30 spores per chain form curled hooks or spirals with 1–2 turns. Spore ornamentation folded or warty.

Inorganic salts-starch agar: moderate growth, surface wrinkled, aerial mycelium only traces of cream colored mycelium, substrate mycelium pale brown, no diffusible pigment. Oatmeal agar: good growth, surface farinaceous, aerial mycelium pale pink, substrate mycelium dark red, no diffusible pigment. Yeast extract-malt extract agar: moderate growth, surface cartilaginous, aerial mycelium cream colored to pinkish, substrate mycelium light brown, no diffusible pigment.

Cell hydrolysates contain galactose, madurose, mannose, and ribose. Phosphatidylinositol, phosphatidylinositolmannosides, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present; diphosphatidylglycerol, phosphatidylethanolamine, and phosphatidylglycerol absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin is hydrolyzed and nitrate reduced. Degrades casein, DNA, elastin, gelatin, hypoxanthine, and tyrosine. Positive for acetoin, arginine dihydrolase, citrate lyase, β-galactosidase, lysine decarboxylase, ornithine decarboxylase, and urease production activities. L-Rhamnose and sucrose are utilized as sole carbon source, but L-arabinose, cellobiose, *meso*-inositol, D-fructose, D-mannose, D-raffinose, and D-xylose are not.

DNA G+C content (mol%): 66.0 (T_m).

Type strain: ATCC 33580, CIP 107009, DSM 43678, NBRC 14687, IMET 9582, INA 2488, JCM 3324, KCTC 9285, PCM 2201, VKM Ac-913.

Sequence accession no. (16S rRNA gene): U48982, X97892.

22. **Nonomuraea spiralis** corrig. (Meyer 1979) Zhang, Wang and Ruan 1998b, 420^{VP} (*Actinomadura spiralis* Meyer 1979, 39; *Microtetraspora spiralis* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

spi.ra′lis. N.L. fem. adj. *spiralis* (from L. n. *spira* coil; and L. suff. *alis -is -e*, suffix denoting pertaining to), coiled, referring to the morphology of the spore chains.

Spore chains in spirals of 2–5 turns, closely packed or more or less loose spirals in pseudoverticillate arrange-

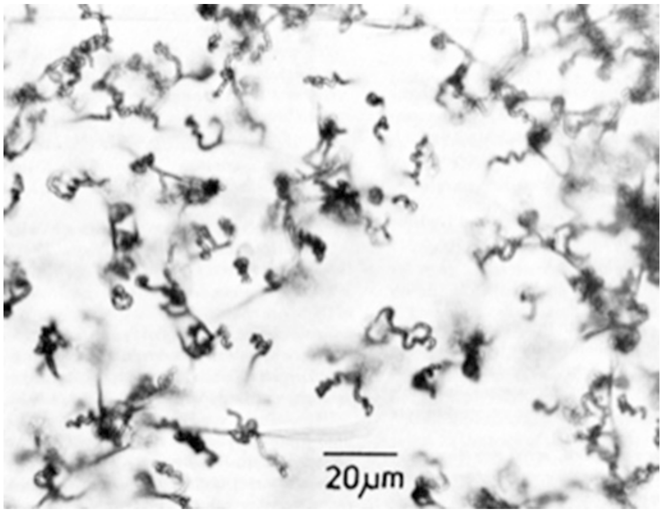

FIGURE 381. *Nonomuraea spiralis*, type strain IMET 9621. Sporulating aerial mycelium. Grown on oatmeal-nitrate agar at 28°C for 18 d.

FIGURE 382. *Nonomuraea spiralis*, type strain IMET 9621. Electron micrograph of spore chain.

ment along short straight aerial hyphae (Figure 381 and Figure 382). 10–15 Spores per chain. Spores spherical to subspherical. Spore surface folded.

Inorganic salts-starch agar: poor growth, surface leathery, aerial mycelium absent, substrate mycelium yellow to yellowish brown, no diffusible pigment. Oatmeal agar: good growth, surface woolly to farinaceous, aerial mycelium white to yellowish white, substrate mycelium yellow to yellowish brown, no diffusible pigment. Oatmeal-nitrate agar: good growth, surface farinaceous, aerial mycelium white, substrate mycelium whitish, no diffusible pigment. Peptone-glucose medium: poor growth, surface leathery, aerial mycelium absent, substrate mycelium yellow to yellowish brown, no diffusible pigment. Yeast extract-malt extract agar: moderate growth, surface farinaceous, aerial mycelium white to yellowish, substrate mycelium yellow to yellowish brown; no diffusible pigment.

Cell hydrolysates contain madurose, mannose, and ribose. Diphosphatidylglycerol, phosphatidylinositolmannosides, ninhydrin and sugar positive phospholipids, and hydroxylated phosphatidylethanolamine are present, but phosphatidylethanolamine, phosphatidylglycerol, and phosphatidylinositol are absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin is hydrolyzed and nitrate is reduced. Positive for acetoin and β-galactosidase activities, but negative for arginine dihydrolase, citrate lyase, gelatinase, lysine decarboxylase, ornithine decarboxylase, and urease activities. D-Mannose, L-rhamnose, sucrose, and D-xylose are used as sole carbon sources, but L-arabinose, cellobiose, D-fructose, *meso*-inositol, and D-raffinose are not.

DNA G+C content (mol%): 68.1 (T_m).

Type strain: ATCC 35114, CCM 3426, BCRC 13309, CIP 106923, DSM 43555, NBRC 14097, IMET 9621, JCM 3286, KCTC 9286, NCIMB 11633, NRRL B-16098, VKM Ac-853.

Sequence accession no. (16S rRNA gene): U48983.

23. **Nonomuraea turkmeniaca** corrig. (Terekhova, Galatenko and Preobrazhenskaya 1982) Zhang, Wang and Ruan 1998b, 420[VP] (*Actinomadura turkmeniaca* Terekhova, Galatenko and Preobrazhenskaya 1982, 87; *Microtetraspora turkmeniaca* Kroppenstedt, Stackebrandt and Goodfellow 1990a, 148)

turk.me.ni.a′ca. N.L. fem. adj. *turkmeniaca* pertaining to Turkmen.

Spore chains with spirals of 3–5 turns. Spore ornamentation smooth.

Violet to red substrate mycelium, traces of aerial hyphae, and a pink to violet soluble pigment are formed on oatmeal agar.

Cell hydrolysates contain madurose, mannose, and ribose. Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present, but phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositolmannosides are absent.

Esculin is hydrolyzed and nitrate reduced. Degrades casein, gelatin, hypoxanthine, and starch. Positive for acetoin, arginine dihydrolase, citrate lyase, β-galactosidase, lysine decarboxylase, ornithine decarboxylase, and urease, activities. L-Arabinose, D-fructose, *meso*-inositol, D-mannose, D-raffinose L-rhamnose, sucrose, and D-xylose, are used as sole carbon sources.

DNA G+C content (mol%): not determined.

Type strain: ATCC 49501, CIP 107010, DSM 43926, JCM 6836, NBRC 14348, IMET 9747, INA 3344, KCTC 9287, NRRL B-16246, VKM Ac-852.

Sequence accession no. (16S rRNA gene): AF277201.

Additional organisms

1. **Nonomuraea terrinata** Quintana, Maldonado and Goodfellow 2003, 5[VP]

te.rri.na′ta L. fem. n. *terra* soil; L. part. fem. adj. *nata* born; N.L. fem. part. adj. *terrinata* born from the soil, referring to the source of the isolate.

Spore chains of 8–15 spores, irregular pseudosporangia. Grows well between 20 and 37°C.

A white to ochre substrate mycelium and an abundant aerial mycelium are formed on oatmeal agar, but soluble pigments are not.

Cell hydrolysates contain madurose.

Diphosphatidylglycerol, phosphatidylethanolamine, ninhydrin and sugar positive phospholipids, hydroxylated phosphatidylethanolamine, and uncharacterized glycolipids are present, but phosphatidylglycerol is absent.

Additional chemotaxonomic data are given in Table 284, and the fatty acid pattern of the type strain is shown in Table 285.

Esculin is hydrolyzed, but nitrate is not reduced. Degrades casein, DNA, hypoxanthine, and starch, but not elastin, gelatin, tyrosine, or xanthine.

Source: soil collected in South Korea.

DNA G+C content (mol%): not determined.

Type strain: E626, DSM 44505, NCIMB 13942.

Sequence accession no. (16S rRNA gene): AF302078.

Genus VII. **Planobispora** Thiemann and Beretta 1968, 157[AL]

Gernot Vobis, Nicole Lodders and Peter Kämpfer

Pla.no.bi.spo′ra. Gr. n. *planos* wanderer, tramper; L. adv. num. *bis* twice (double); Gr. fem. n. *spora* a seed, and in biology a spore; N.L. fem. n. *Planobispora* a motile, double-spored organism.

Substrate and aerial mycelia are formed on agar media. Substrate hyphae (0.5–1.0 μm in diameter) are nonfragmenting, branched, and septate. Aerial hyphae (1.0 μm in diameter) are sparsely branched and septate. Gram-stain-positive and non-acid-fast. **Cylindrical to clavate sporangia** (1.0–1.2 μm × 6.0–8.0 μm), each containing a **longitudinal pair of spores**, are developed singly or in bundles on short ramifications of the **aerial hyphae**. The **spores** (zoospores) are oblong and cylindrical with rounded ends, and are **motile** by means of peritrichous flagella. Colonies developed on agar media are flat or occasionally elevated, the **substrate mycelium either without distinctive color or rose colored**. The **aerial mycelium**, which is formed only on certain agar media, is **white or with a light rose tinge**. Strains grow well under aerobic conditions. Chemoorganotrophic and mesophilic, growing well at 28–40°C and pH 6.0–9.0. Cell walls contain *meso*-diaminopimelic acid and whole-cell hydrolysates contain madurose as the diagnostic sugar. Contains diphosphatidylglycerol, phosphatidylethanolamine, hydroxylated phosphatidylethanolamine, and ninhydrin and sugar positive phospholipids as predominant phospholipids. Major menaquinones are MK-9(H_4), MK-9(H_2), and MK-9(H_0). Major types of fatty acids are C_{17} 10-methyl and C_{16} iso-branched fatty acids.

DNA G+C content (mol%): 70–71 (Im).

Type species: **Planobispora longispora** Thiemann and Beretta 1968c, 157[AL].

Further descriptive information

Phylogeny. On the basis of 16S rRNA gene sequence analyses, the genus *Planobispora* is grouped in the family *Streptosporangiaceae*. This is also shown by other 16S rRNA gene sequence studies of this group (Goodfellow et al., 1990b; Goodfellow and Quintana, 2005; Stackebrandt et al., 1997; Zhang et al., 1998b). Within this family, most genera are defined on the basis of distinct chemotaxonomic and morphological properties (Table 275). The genus encompasses two species with validly published names. Representatives of these form a distinct line in the 16S rRNA *Streptosporangiaceae* gene tree (Goodfellow and Quintana, 2005; Figure 383). Their nearest relatives within the family *Streptosporangiaceae* are the genera *Planomonospora*, *Streptosporangium*, and *Sphaerisporangium*. Similarity values between the genera *Planomonospora* (with the exception of *Planomonospora venezuelensis*) and *Planobispora* range from 97.1–96.2%, between the genera *Planobispora* and *Streptosporangium* from 96.5–93.8%, and between the genera *Planobispora* and *Sphaerisporangium* from 96.2–96.1%. As pointed out in the *Planomonospora* chapter, *Planomonospora venezuelensis* shows a closer relationship to *Planobispora* in the phylogenetic tree than to the genus *Planomonospora*. 16S rRNA gene signature nucleotide positions that can be used to differentiate genera of the family *Streptosporangiaceae* are described by Ara and Kudo (2007). Three of the signature nucleotide positions differ between *Planomonospora* (with the exception of *Planomonospora venezuelensis*) and *Planobispora*: 625 (C and G, respectively), 627 (A and G, respectively), 990:1215 (C–G and C–G/U–G, respectively). For two of the three signature nucleotide positions, *Planomonospora venezuelensis* has the same signature as the genus *Planobispora*: 625 (G) and 627 (G).

Cell morphology. The hyphae of the substrate mycelium are 0.5–1.0 μm in diameter, irregularly branched, and occasionally septate. Fragmentation of hyphae is not apparent either on solid agar media or in liquid cultures (Thiemann and Beretta, 1968). The hyphae of the aerial mycelium are 1.0 μm in diameter, long, slender, and wavy, with few lateral branches, and grow more or less parallel to the surface of the substrate. The aerial mycelium is extremely hydrophobic (Thiemann, 1970).

Cylindrical to clavate sporangia are formed on short side branches of aerial hyphae (Figure 384A). They can be arranged singly or in bundles (Suzuki et al., 2001a; Thiemann and Beretta, 1968; Vobis, 1989). Each sporangium contains a longitudinal pair of spores (Figure 384E, F, G).The mean size of a sporangium is 6.0–8.0 μm × 1.0–1.2 μm (Thiemann, 1974a). The sporangia are connected to the main axis of the sporangiophore by short supporting pedicels (Figure 384E, F), which are only 1.0–3.0 μm

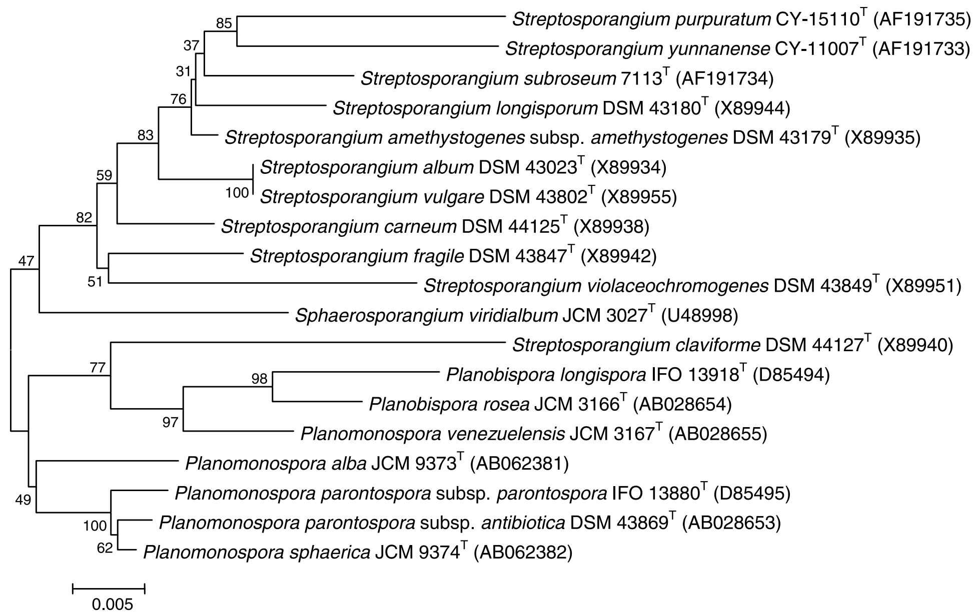

FIGURE 383. Neighbor-joining tree based on 16S rRNA gene sequences of *Planobispora* species and close relatives. The numbers of the nodes indicate the level of bootstrap support (%) based on an analysis of 1000 resampled data sets. The scale bar = 0.5 differences in 16S rRNA gene sequences.

long, very fragile, and collapse easily (Thiemann and Beretta, 1968). As supposed by Bland and Couch (1981), the spores originate from simple transformation of sporogenous hyphae (Figure 384F). The tip of the sporangiophore prolongates until it reaches the length of a ripe sporangium (Figure 384F6). The sporogenous hypha septates from the pedicel and divides into two equal spore-sized segments. The following sporangial primordium continues with the apical outgrowth of the sporangiophore (Figure 384F7). The young spores occupy the sporangial volume (Figure 384G), rounding up later during maturation (Figure 384E, F 1–4). The sporangial envelope is a continuation of the hyphal sheath of the sporangiophore (Figure 384B, C). It is interspersed by longitudinally orientated fibrillar elements, converging like a buttress at the tip of the sporangium (Figure 384B). Between the two spores, a diaphragm is formed transversely, originating from the inner side of the sporangial envelope (Figure 384D, E). In general, the sporangial envelopes are smooth (Thiemann and Beretta, 1968). The studies of Suzuki et al. (2001a) demonstrate various morphological differences in *Planobispora* isolates with clavate to pyriform sporangia, warty sporangial surface, and even three-spored sporangia. The sporangia arranged in bundles form either fan-shaped tufts (Miyadoh et al., 1997), resembling a "half-side" palm leaf pattern like *Planomonospora venezuelensis*, or parallel rows analogous to *Planomonospora parontospora* (Suzuki et al., 2001a).

The spores measure 1.0–1.2 µm × 2.6–4.0 µm, they are oblong with round ends, occasionally slightly curved. The spores (zoospores) are motile by means of peritrichous flagella (Thiemann, 1974a).

The mode of spore liberation was studied by Thiemann (1970). If sporangia of *Planobispora rosea* are dipped into water, the upper spore is released at first through the tip of the sporangium. The lower one remains blocked in the sporangium. Only when the sporangium is broken off at the sporangiophore, the basal spore can be expulsed through the lower end. The central diaphragm (Figure 384D, E), which was called "transverse septum" by Thiemann (1970), occupies an essential function in this process. It separates the two spores by swelling and pushes the spores in opposite directions out of the sporangium. The spores become motile only some time after being dispersed. In spite of good culture conditions, only 2–5% of the spores become motile. The spores germinate with one or two polar germ tubes; occasionally lateral germination is observed (Thiemann and Beretta, 1968).

Cell-wall composition. The peptidoglycan of the cell wall contains *meso*-DAP with madurose (3-*O*-methyl-D-galactose) as the characteristic sugar of whole-cell hydrolysates (Kroppenstedt and Kutzner, 1976, 1978). This chemical cell-wall composition is in accordance with cell-wall type III and sugar pattern B of the classification scheme of Lechevalier and Lechevalier (1970b).

The phospholipids of the cell membranes consist of unknown glucosamine-containing phospholipids, phosphatidylinositol, phosphatidylethanolamine, and diphosphatidylglycerol (Hasegawa et al., 1979), in accordance with phospholipid type IV of Lechevalier et al. (1981).

The fatty acids consist of straight-chain acids, iso- and 10-methyl branched acids, and unsaturated fatty acids. Anteiso-branched fatty acids are not present (Kroppenstedt and Kutzner, 1978), corresponding to fatty acid type 3c of Kroppenstedt (1985).

The two species of *Planobispora* have the menaquinone type 4a of Kroppenstedt (1985) in common, but show variations. *Planobispora rosea* is characterized by di- and tetrahydrogenated menaquinones with nine isoprene units [MK-9(H_2) and MK-9(H_4)] (Whitham et al., 1993), and *Planobispora longispora* by tetra- and dihydrogenated menaquinones with nine units [MK-9(III, VIII-H_4) and MK-9(H_2)], together with MK-9(H_0) (Kudo et al., 1993; Whitham et al., 1993) (Table 287).

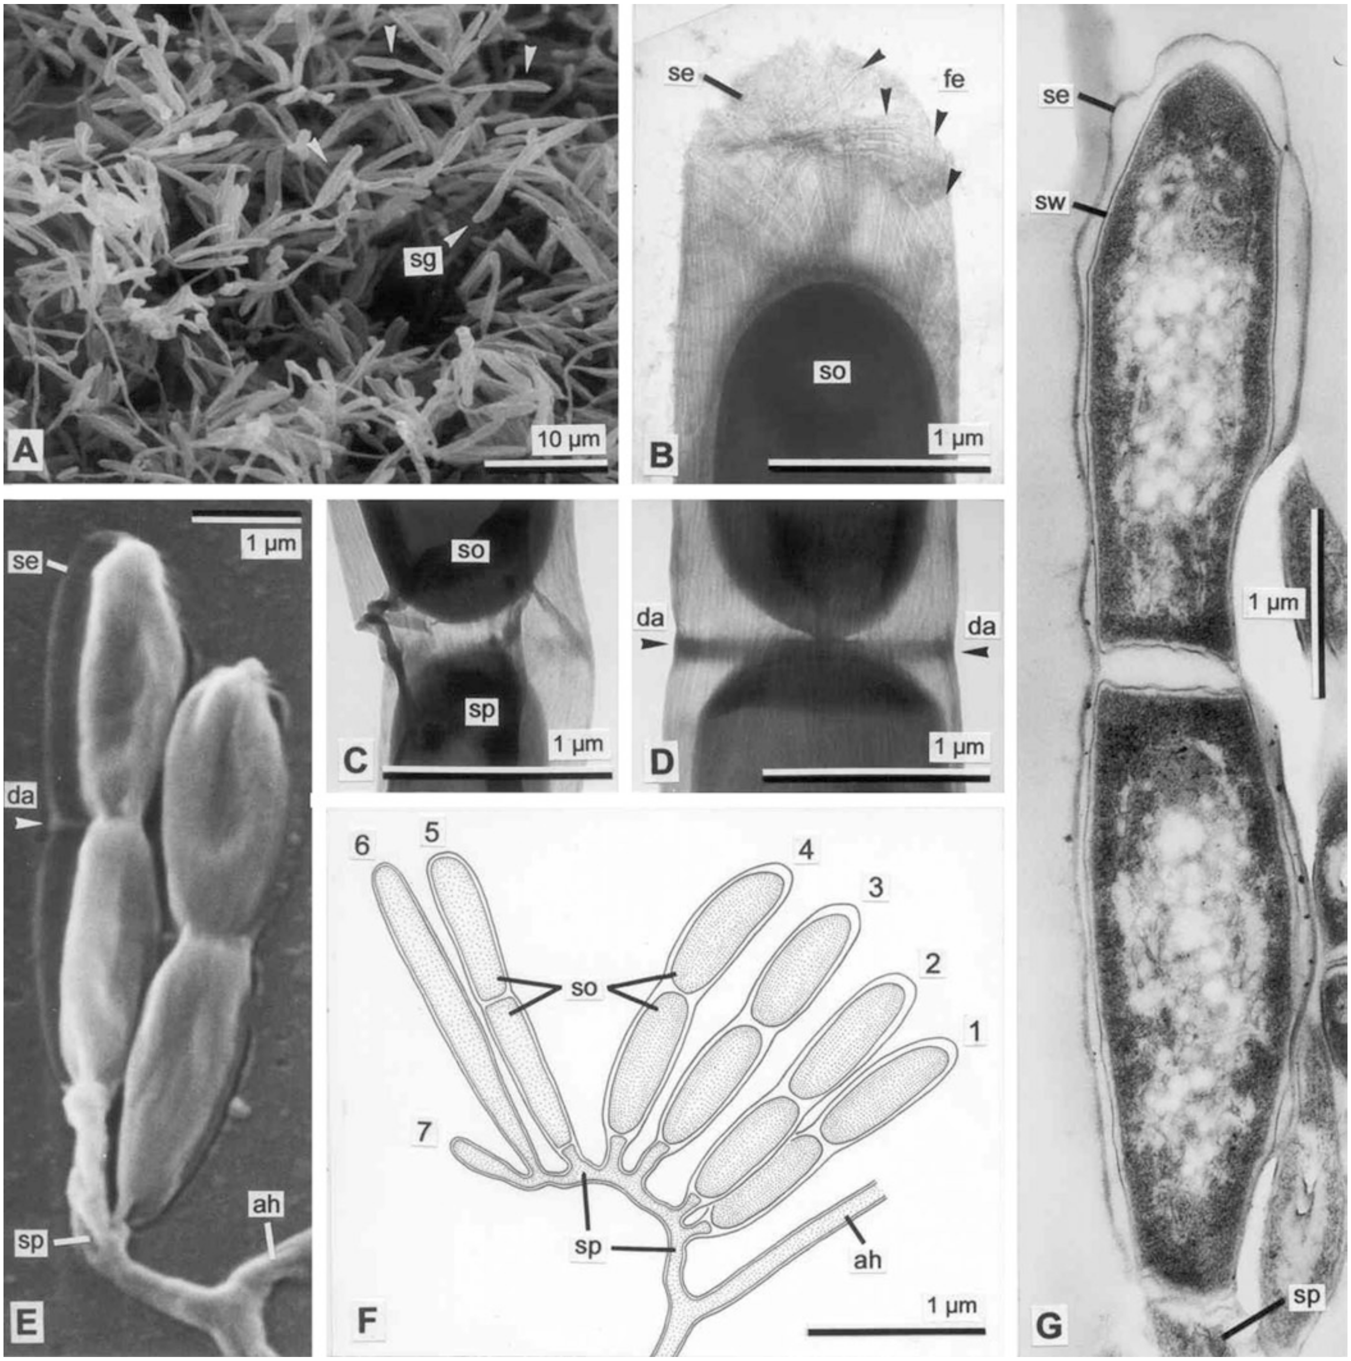

FIGURE 384. Two-spored sporangia of *Planobispora rosea* ATCC 23866 (A, C, D, E, F) and *Planobispora longispora* ATCC 23867 (B, G). A, aerial mycelium with numerous sporangia (SEM); B, tip of the sporangial envelope with fibrous elements (TEM); C, transition from sporangiophore to sporangium (TEM); D, diaphragm in the center (TEM); E, two mature sporangia (SEM); F, sporangiophore with a bundle of 7 sporangia in different stages of development: mature sporangia (1–4), young sporangium (5), immature, still unsegmented sporangium (6) and sporangial primordium (7); G, young sporangium, separated from the sporangiophore and divided in two spore segments (TEM) (see also F 5). Abbreviations: SEM, scanning electron microscope; TEM, transmission electron microscope; ah, aerial hypha; da, diaphragm; fe, fibrous elements; se, sporangial envelope; sg, sporangium; so, spore; sp, sporangiophore; sw, spore wall.

Colony morphology. Substrate and aerial mycelia develop on a variety of agar media. The colonies are mostly flat or occasionally elevated and have a smooth surface. On yeast extract-malt extract agar and on Bennett agar the colonies of *Planobispora longispora* are crusty (Thiemann and Beretta, 1968); *Planobispora rosea* has slightly wrinkled surfaces on Bennett agar and Hickey–Tresner agar (Thiemann, 1970). No distinctive color of the mycelium is formed by *Planobispora longispora* (Thiemann and Beretta, 1968); *Planobispora rosea* produces rose-colored substrate mycelium and white aerial mycelium with

rose tinge (Thiemann, 1970). For *Planobispora longispora*, the development of the aerial mycelium and formation of sporangia are promoted by oatmeal, calcium malate, and soil agars (Thiemann and Beretta, 1968). Hickey–Tresner agar and glycerol-asparagine agar have the same effect on *Planobispora rosea* (Thiemann, 1970).

Planobispora rosea strain ATCC 53773 produces the antibiotic GE 2270, a thiazolyl peptide substance inhibiting bacterial protein synthesis (Selva et al., 1995).

Metabolism. Members of *Planobispora* are aerobic, growing well on the various standard culture media recommended by Waksman (1961) and Shirling and Gottlieb (1966). The type strains of *Planobispora longispora* and *Planobispora rosea* can utilize L-arabinose, cellobiose, fructose, glucose, glycogen, inositol, maltose, mannitol, and starch as sole carbon sources. Adonitol, D-arabinose, erythritol, ethanol, glycerol, inulin, lactose, mannose, α-methyl-D-glucoside, raffinose, sorbitol, and sucrose are not utilized (Goodfellow and Pirouz, 1982; Thiemann, 1974a). Acetamide and serine are not utilized as sole carbon and nitrogen sources (Goodfellow and Pirouz, 1982). Further physiological features and degradation abilities are also shown in Table 288.

[b]Data from Thiemann (1970).

[c]Data from Goodfellow and Pirouz (1982).

[d]Data from Thiemann and Beretta (1968).

Strains of *Planobispora* are mesophilic. Good growth occurs at 28–40°C, with no growth at 20°C or 45°C (Goodfellow and Pirouz, 1982; Thiemann, 1974a). Cultures grow well at pH 6.0–9.0. As an exception, *Planobispora longispora* grows at pH 5.0 on oatmeal agar (Thiemann and Beretta, 1968). Strains grow in the presence of brilliant green (up to 0.02%, w/v), crystal violet (up to 0.001%, w/v), and pyronine (0.01%, w/v), but they do not tolerate lysozyme (0.005%, w/v) or NaCl (3.0%, w/v) (Goodfellow and Pirouz, 1982). Nitrate is reduced to nitrite and phosphatase is produced. The type strains of *Planobispora longispora* and

Planobispora rosea are able to degrade arbutin, casein, elastin, DNA, gelatin, keratin, RNA, starch, tyrosine, and Tween 20, 40, 60, and 80. The following compounds are not degraded: adenine, cellulose, guanine, hippurate, testosterone, xanthine, and xylan (Goodfellow and Pirouz, 1982) (see Table 288).

Planobispora longispora and *Planobispora rosea* are sensitive to the antibiotics kanamycin, neomycin, novobiocin, tobramycin, and penicillin. They are not sensitive to cephalosporin, lincomycin, rifampin, and streptomycin. *Planobispora longispora* is sensitive to dimethylchlortetracycline, and *Planobispora rosea* is sensitive to gentamicin (Goodfellow and Pirouz, 1982) (Table 287).

Ecology. The genus *Planobispora* was regarded for a long time as a very rare microorganism, known only from a few localities. Several strains, including the type strains, were isolated from two soil samples collected from a river bank in Venezuela. The pH values of the two samples were 5.3 and 7.6 (Thiemann, 1970). Further strains were isolated by D. Schäfer from a soil sample collected in Namibia (Vobis, 1989). Kizuka et al. (1997) recovered *Planobispora* strains from soil originating from arid regions of South Africa. More recently, Suzuki et al. (2001a) tested 1467 soil samples collected from all parts of the world. Only 3.5% of the samples tested contained *Planobispora* strains. The pH value of the samples ranged from 6.2–8.1, nearly 90% in the small range from 7.0–7.9, indicating that the organisms prefer neutral to slightly alkaline environments. The positive samples were collected in Ecuador, Egypt, French Guiana, India, and Madagascar, whereas no isolates were obtained from samples of temperate areas in Europe, North America, and Oceania. The geographical distribution seems to be restricted to tropical and subtropical zones between latitude 35°N and 35°S (Suzuki et al., 2001a).

Enrichment and isolation procedures

Unfortunately, Thiemann and coworkers never published the isolation procedures they used. The traditional baiting technique as described by Bland and Couch (1981) was successfully applied (Vobis, 1989). Kizuka et al. (1997) could isolate *Planobispora* strains by a centrifugation method. Suzuki et al. (2001a) developed an efficient selective isolation method using humic acid–trace salts gellan gum medium (HSG) containing 0.05% nitrohumic acid, 3 mM $CaCl_2$, 5 mM CHES (*N*-cyclohexyl-2-amino-ethanesulfonic acid), and 0.7% gellan gum, with addition of seven antimicrobial agents (μg/ml): trimethoprim (50), nalidixic acid (50), enoxacin (20), sodium ampicillin (2), streptomycin sulfate (1), cycloheximide (50), and nystatin (50). The presence of trace salts ($FeSO_4 \cdot 7H_2O$, $MnCl_2 \cdot 4H_2O$, $ZnSO_4 \cdot 7H_2O$, and $NiSO_4 \cdot 6H_2O$ with 0.0001% concentration of each), the alkaline environment (pH 9.0), and the incubation temperature of 32–37° C stimulate the formation of sporangia. This morphological characteristic is indispensable to recognize *Planobispora* strains under the microscope. Five hundred milligrams of air-dried soil samples are treated in dry heat at 90°C for 60 min. After cooling, each sample is flooded with 2 ml of a solution of 0.1% skim milk (unsterilized), 0.01% Tween 80 in 5 mM CHES (pH 9.0), and incubated with occasional stirring at 35°C for 1 h. After centrifugation (1000 × *g* for 10 min), 800 μl of the supernatant is diluted with sterile saline, and aliquots are spread onto HSG plates. They are incubated for 14–21 d at 32°C. The colonies grown in these enrichment cultures are controlled microscopically. Pure isolates are obtained by streaking onto HSG and tested for zoospore production by flooding with a solution containing 0.1% skim milk in 5 mM CHES (pH 9.0).

Maintenance procedures

For some weeks or even months, cultures can be stored at room temperature in hermetically closed slant culture tubes on agar medium that support good growth of substrate and arial mycelium and production of sporangia. For long-term preservation, strains must be processed as described for other aerobic actinomycetes. Among others, lyophilization is a recommended method.

Differentiation of the genus *Planobispora* from other genera

The genus *Planobispora* may be confused morphologically with members of genera that can produce pairs of spores on aerial and/or substrate mycelia: *Actinobispora*, *Actinomadura*, *Microbispora*, *Microtetraspora*, *Thermobispora* (Miyadoh et al., 1997; Suzuki, 2001; Wang et al., 1996c; Zhang et al., 1998b), and the former genera *Elytrosporangium*, *Kitasatoa*, and *Microellobosporia*, now belonging to the genus *Streptomyces* (Williams et al., 1989). In opposition to *Planobispora*, the spores of those genera are not produced in a sporangium, and their spores are not motile in aquatic habitats. Confusion with strains of the genus *Dactylosporangium*, which produce motile spores within few-spored, cylindrical to clavate sporangia on substrate hyphae, can finally be avoided by determining the cell-wall chemotype. *Planobispora* with cell-wall type III and sugar pattern B distinguishes from *Dactylosporangium* having chemotype II and sugar pattern D.

Taxonomic comments

The majority of the genera classified in the aggregate group "maduromycetes" (Goodfellow, 1989a), including *Planobispora*, were assigned to the family *Streptosporangiaceae* (Goodfellow, 1992; Goodfellow et al., 1990b). Ward-Rainey et al. (1997) emended the description of the family *Streptosporangiaceae* and included the genera *Herbidospora*, *Microbispora*, *Microtetraspora*, *Planobispora*, *Planomonospora*, and *Streptosporangium*. This taxonomical concept was underpinned by Miyadoh et al. (1997). Subsequently, the family *Streptosporangiaceae* was extended by addition of the genera *Acrocarpospora*, *Nonomuraea*, *Planotetraspora*, and *Sphaerisporangium* corrig. (Ara and Kudo, 2007; Miyadoh et al., 2001).

Differentiation of species of the genus *Planobispora*

The two species presently described cannot be clearly differentiated on the basis of morphology. Tests for utilization of 28 carbon sources and degradation of 21 compounds all show only 10% deviation between the two species (Table 288). Besides other distinguishing physiological and cultural characteristics, the colors of substrate and aerial mycelium (Thiemann, 1970) and the menaquinone composition (Kudo et al., 1993; Whitham et al., 1993) are additional features to differentiate the two species (Table 287).

List of species of the genus *Planobispora*

1. **Planobispora longispora** Thiemann and Beretta 1968, 157[AL]

lon.gi.spo′ra. L. adj. *longus* long; Gr. n. *spora* a seed, and in biology a spore; N.L. n. *longispora* (nominative in apposition) the long spore.

Sporangial development is supported by soil, calcium malate, and oatmeal agars. Spores are straight to slightly curved with rounded ends, measuring 1.0–1.2 × 2.6–4.0 µm. They are motile by peritrichous flagella.

No specific color occurs either in the aerial or in the substrate mycelium. The aerial mycelium is white and the substrate mycelium hyaline to creamy colored. No soluble pigments are produced.

Good growth with abundant aerial mycelium occurs on oatmeal agar. On yeast extract-malt extract, Hickey–Tresner, Bennett, and peptone-beef extract agars, colonies also grow well, but aerial mycelium is not developed.

Amygdalin is used for growth; galactose, melezitose, and salicin are not. Hypoxanthine is degraded; esculin and chitin are not degraded. Melanoid pigments are not produced. Litmus milk is coagulated and peptonized.

Contains tetra- and dihydrogenated menaquinones with nine units [MK-9(III,VIII-H_4) and MK-9(H_2)], together with MK-9(H_0)

DNA G+C content (mol%): 71 (T_m).

Type strain: ATCC 23867, DSM 43041, CBS 115.69, JCM 3092, NBRC 13918, VKM Ac-700.

Sequence accession no. (16S rRNA gene): D85494.

2. **Planobispora rosea** Thiemann 1970, 251[AL]

ro′se.a. L. fem. adj. *rosea* rose-colored.

Sporangial development is promoted by all media on which aerial mycelium is formed, e.g. on soil and Hickey–Tresner agars. The spores are elongated and fusiform, with rounded ends, 1.0–1.2 µm × 3.0–3.5 µm. They are motile by peritrichous flagella.

Substrate mycelium in most media is rose colored; if aerial mycelium is developed, it always has a light rose tinge.

On Bennett, peptone-beef extract and potato plug agars the colonies grow well, are slightly wrinkled or flat and rose colored; no aerial mycelium is developed. Good growth occurs also on Hickey–Tresner agar and the colonies are slightly wrinkled and yellow-amber colored with abundant aerial mycelium. Colonies grow well on oatmeal agar; they are smooth and rose colored and aerial mycelium is moderately developed showing a rose tinge. On glycerol-asparagine agar, growth is moderate and the colonies are smooth, flat, and hyaline; abundant aerial mycelium, white with a rose tinge, is formed.

Galactose, melezitose, and salicin are used for growth; amygdalin is not. Esculin and chitin are degraded, hypoxanthine is not hydrolyzed. Litmus milk is neither coagulated nor peptonized.

Contains di- and tetrahydrogenated menaquinones with nine isoprene units [MK-9(H_2) and MK-9(H_4)].

DNA G+C content (mol%): 70 (T_m).

Type strain: ATCC 23866, DSM 43051, JCM 3166, NBRC 15558, NRRL B-8121, VKM Ac-1318.

Sequence accession no. (16S rRNA gene): AB028654.

Genus VIII. **Planomonospora** Thiemann, Pagani and Beretta 1967, 29[AL]

Gernot Vobis, Nicole Lodders and Peter Kämpfer

Pla.no.mo.no.spo′ra. Gr. n. *planos* wanderer, vagabond; Gr. adj. *monos* alone, single; Gr. fem. n. *spora* a seed, and in biology a spore; N.L. fem. n. *Planomonospora* a motile, single spored organism.

Substrate and aerial mycelium developed on various agar media. Substrate hyphae (0.6–1.0 µm in diameter) are nonfragmenting, irregularly branched, and occasionally septated. Aerial hyphae are sparsely branched and rarely septated. Organisms are Gram-stain-positive and non-acid-fast. **Cylindrical to clavate sporangia** (1.0–1.5 µm × 3.5–5.5 µm) **are formed in bundles on the aerial mycelium**, arranged either in narrow parallel rows resembling rows of bananas or in an open palm leaf pattern. **Each sporangium contains a single spore**. **Spores (zoospores) are oblong to fusiform and motile by means of peritrichous flagella**. Growth under aerobic conditions. Colonies developed on complex agar media are raised or flat with rugose or smooth surfaces. Substrate mycelium may be grayish yellow, light orange, rose, yellowish pink, or violet-brown. Aerial mycelium is white, grayish white, light rose, or pink. Chemoorganotrophic, mesophilic, grows well at 28–37°C and from pH 7.0–8.0.

Cell walls contain *meso*-diaminopimelic acid and whole-cell hydrolysates contain madurose as the diagnostic sugar. Contains diphosphatidylglycerol, phosphatidylethanolamine, hydroxylated phosphatidylethanolamine, and ninhydrin and sugar positive phospholipids as predominant phospholipids. Major menaquinones are MK-9(H_4), MK-9(H_2), and MK-9(H_0). Major types of fatty acids are C_{17} 10 methyl and C_{16} iso branched fatty acids.

DNA G+C content (mol%): 72 (T_m).

Type species: **Planomonospora parontospora** Thiemann, Pagani and Beretta 1967, 29[AL].

Further descriptive information

Phylogeny. 16S rRNA gene sequence analyses place the genus *Planomonospora* in the family *Streptosporangiaceae*. This is confirmed by other 16S rRNA gene sequence studies of this group (Goodfellow et al., 1990b; Goodfellow and Quintana, 2005; Stackebrandt et al., 1997; Zhang et al., 1998b). Within this family, genera are defined on the basis of distinct chemotaxonomic and morphological properties (Table 275). The taxon encompasses four species and two subspecies with validly published names. Representatives of each of these validly described species form a distinct line in the 16S rRNA *Streptosporangiaceae* gene tree (Goodfellow and Quintana, 2005; Figure 383).

[b]Data compiled from [e]Thiemann et al. (1967), [g]Thiemann et al. (1968a), [f]Thiemann, (1970), [c]Goodfellow and Pirouz (1982), and [d]Mertz, (1994). Deviations are indicated by superscript letters.

Planomonospora species and subspecies form a distinct clade in the 16S rRNA gene tree with the exception of *Planomonospora venezuelensis* (Figure 383). Their nearest relatives within the family *Streptosporangiaceae* are the genera *Planobispora*, *Streptosporangium*, and *Sphaerisporangium* corrig. Similarity values between the genera *Planomonospora* (with the exception of *Planomonospora venezuelensis*) and *Planobispora* range from 97.1–96.2%, between the genera *Planomonospora* and *Streptosporangium* from 98.1–95.3%, and between the genera *Planomonospora* and *Sphaerisporangium* from 96.1–95.9%. The 16S rRNA gene sequence of *Planomonospora venezuelensis* differs in 2.2–2.5% from the sequences of the other species of the genus *Planomonospora* (similarity values between the sequences of *Planomonospora venezuelensis* and the other sequences of the genus *Planomonospora* range from 97.5–97.8%). Although similar differences in gene sequences can be found between *Planomonospora venezuelensis* and the genus *Planobispora* (differences of 2.2–2.8%; similarity values range from 97.6–97.8%), *Planomonospora venezuelensis* shows a closer relationship to *Planobispora* in the phylogenetic tree than to the genus *Planomonospora*. 16S rRNA gene signature nucleotide positions that can be used to differentiate genera of the family *Streptosporangiaceae* are described by Ara and Kudo (2007). Three of the signature nucleotide positions differ between *Planomonospora* (with the exception of *Planomonospora venezuelensis*) and *Planobispora*: 625 (C and G, respectively), 627 (A and G, respectively), 990:1215 (C–G and C–G/U–G, respectively). For two of the three signature nucleotide positions, *Planomonospora venezuelensis* has the same signature as the genus *Planobispora*: 625 (G) and 627 (G).

Cell morphology. Strains of *Planomonospora* produce substrate and aerial mycelium on solid media. Substrate hyphae have diameters of 0.6–1.0 μm, and are irregularly branched, septate, and do not fragment on agar media or in liquid-submersed cultures (Mertz, 1994; Thiemann, 1970). Twisting and swelling occurs in *Planomonospora parontospora* (Thiemann et al., 1967, 1968a). Hyphae grow profusely within agar media forming a compact layer on the surface of the substrate mycelium (Thiemann, 1974b). The diameter of aerial hyphae is 0.5–1.0 μm. They are sparsely branched and, in *Planomonospora venezuelensis*, usually long, wavy, and slender (Thiemann, 1970). Hyphae of *Planomonospora sphaerica* develop characteristic sphaerical bodies with diameters up to 5 μm on inorganic salts-starch agar (ISP medium 4) (Mertz, 1994).

The characteristic morphological feature common to all *Planomonospora* species is the monosporous sporangium, which is produced only on the aerial mycelium. Two different morphological arrangements of sporangia can be recognized. In *Planomonospora venezuelensis*, sporangia are bundled like the pinnas of palm leaves ("palm leaf pattern"). The sporangia develop sympodially along the tip of an aerial hypha, which functions as a sporangiophore. The first sporangium originates by differentiation of the final segment of the sporangiophore (Figure 385A) and the primordium of the following sporangium arises as a subterminal protrusion at the base of the last formed sporangium, alternately in each case (Figure 385B). This pattern of development leads to a distichous arrangement of two rows of sporangia on opposite sides (Figure 385C, D). Each sporangium is connected to the common axis by a short stalk. Fibrillar

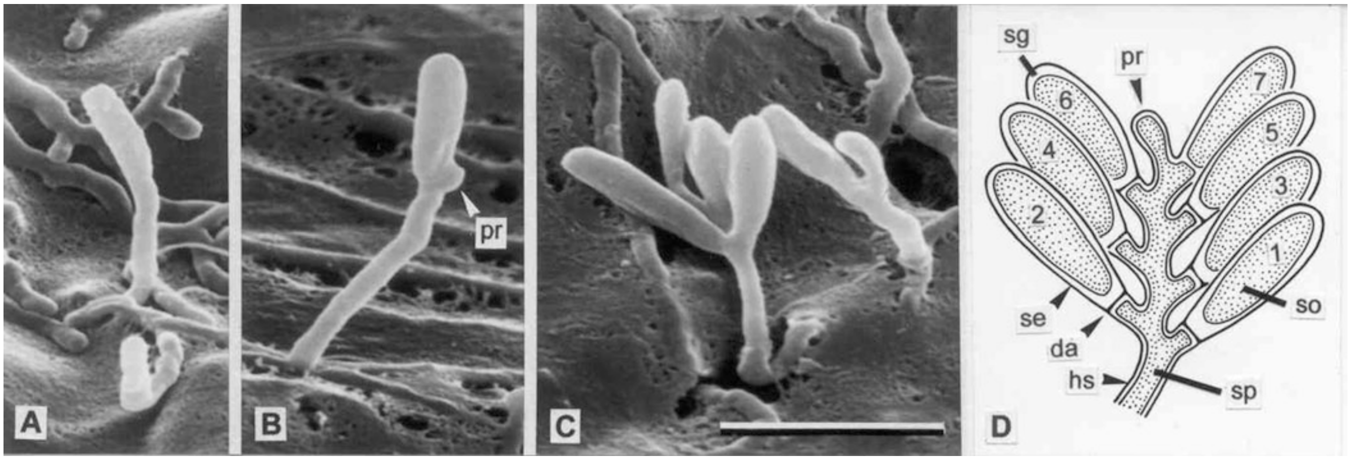

FIGURE 385. Scanning electron micrographs showing ontogenetic development of sporangiophores in *Planomonospora venezuelensis* ATCC 23865 bearing one-spored sporangia in a palm leaf pattern. A, First sporangium produced terminally on an aerial hypha; B, Primordium of the second sporangium protruding at the base of the first sporangium. C, Second sporangium in development (right), sporangiophore with four sporangia (left); D, Sporangiophore with seven sporangia in alternate positions, new sporangial primordium protruding subterminally off the last produced sporangia. Abbreviations: da, diaphragm; hs, hyphal sheath; pr, primordium; se, sporangial envelope; sg, sporangium; so, spore; sp, sporangiophore. Bar = 5 μm.

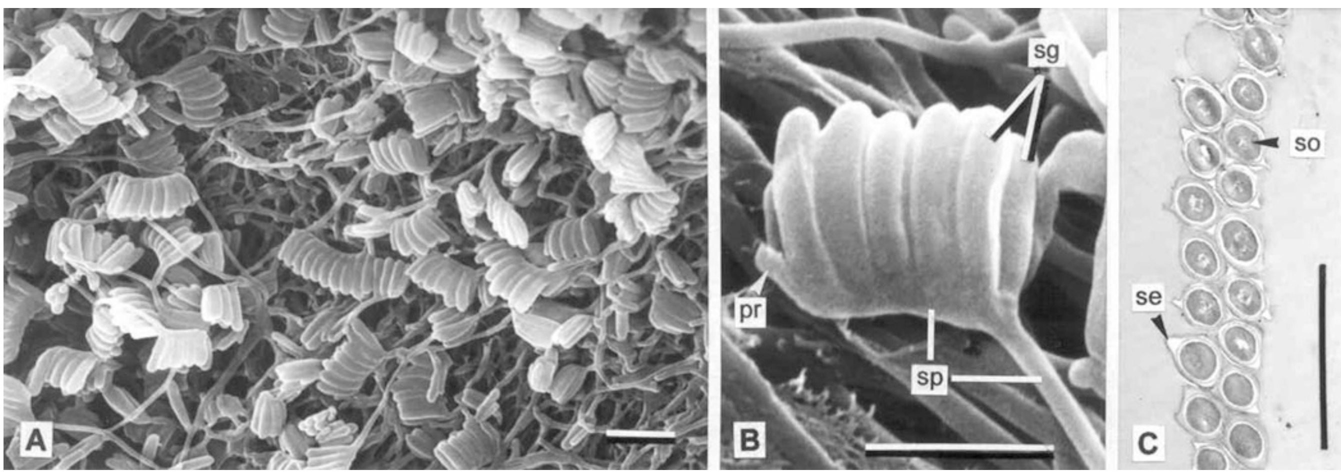

FIGURE 386. Sporangiophores of *Planomonospora parontospora* ATCC 23863. A, Aerial hyphae with numerous sporangial stands; B, sporangiophore bearing a double-row of sessile monosporous sporangia, sporangial primordium protrudes from the sporangiophore apically; C, transverse section of a double row of sporangia, each in alternate position (A, B, scanning electron microscopy; C, transmission electron microscopy). Abbreviations: pr, primordium; se, sporangial envelope; sg, sporangium; sp, sporangiophore. Bars = 5 μm.

elements have been detected on the surface of sporangia (Sharples et al., 1974; Vobis, 1986). The sporangial envelope is a continuation of the hyphal sheath of the sporangiophore (Figure 385D); it retains the hydrophilic character of the aerial hyphae. The morphological appearance of the sporangial strands of *Planomonospora alba*, *Planomonospora parontospora*, and *Planomonospora sphaerica* differ distinctly from those of *Planomonospora venezuelensis*. Sporangia are arranged closely in parallel double rows (Figure 386A). The sporangiophore is slightly bent and can bear up to 60 sporangia, resembling a row of bananas (Mertz, 1994). New sporangia developed from the tip of the sporangiophore (Figure 386B) contribute alternately to each row (Figure 386C). Sporangia are cylindrical with rounded tips, measuring 1.0 μm in diameter and 4.5–5.5 μm in length. Each sporangium is separated from the sporangiophore by a diaphragm (Vobis, 1986). Scanning electron microscope studies show the presence of rostellate structures at the tips of mature and older sporangia, resembling pore-shaped openings or opercula (Locci and Petrolini-Baldan, 1971; Mertz, 1994; Williams, 1970). The fine structure of spore formation was first investigated using transmission electron microscopy by Williams et al. (1973) and Sharples et al. (1974), and reinvestigated by Vobis and Kothe (1985) and Vobis (1986). It can be concluded that sporangial development in *Planomonospora* species follows the same ontogenetical principles as found in other actinomycete genera bearing sporangia on aerial hyphae (Vobis, 1997).

Planomonospora venezuelensis forms fusiform spores, slightly thickened at the terminal end; they are 1.0 μm × 3.0–3.5 μm,

[c]With a rose tinge.

[d]Mertz (1994).

filling the sporangium almost completely, and are motile by peritrichous flagella (Thiemann, 1970, 1974b). The spores of *Planomonospora parontospora* are cylindrical to slightly curved or reniform, and are 1.0–1.5 µm × 3.5–4.5 µm. Flagellation is described as lophotrichous (Lechevalier and Lechevalier, 1970a) or peritrichous (Miyadoh et al., 1997; Thiemann, 1974b). Large clavate spores, 10–15 µm long, which move slowly, may be observed (Thiemann et al., 1967). *Planomonospora alba* and *Planomonospora sphaerica* have cylindrical spores, 1.5 × 4.4 µm on mean, which become motile after immersion in water (Mertz, 1994).

The process of spore release begins immediately after sporangia are placed into water. The sporangia change their optical characteristics and become highly opaque (Thiemann, 1970). The spore is pushed upward through the tip, probably due to swelling of material located at the base of the sporangium. The spores become motile by means of peritrichous flagella 30–40 min after they have been expelled (Thiemann et al., 1967). They remain motile for 5–24 h, during which time spore germination may begin (Thiemann, 1970). One or more germ tubes protrude from the spores terminally and subterminally (Miyadoh et al., 1997). In *Planomonospora alba* and *Planomonospora sphaerica*, motility of the sporangiospores has been reported for 30–60 min (Mertz, 1994). The characteristic spherical bodies of *Planomonospora sphaerica* can germinate, producing germ tubes or promycelia (Mertz, 1994); the structures are considered to be atypical-shaped sporangia (Miyadoh et al., 1997).

Cell-wall composition. The peptidoglycan of the cell walls contains *meso*-diaminopimelic acid (Lechevalier and Lechevalier, 1970a; Mertz, 1994) and the characteristic sugar of whole-cell hydrolysates is madurose (3.0-methyl-D-galactose). The sugars galactose and xylose have also been reported (Mertz, 1994) in *Planomonospora alba* and *Planomonospora sphaerica*. *Planomonospora* has a cell-wall chemotype III and a sugar pattern B (Lechevalier and Lechevalier, 1970b).

Planomonospora species show a number of different menaquinone profiles. Di- and tetrahydrogenated menaquinones with nine units [MK-9(H_2) and MK-9(H_4)] are the major components in *Planomonospora parontospora*, whereas tetrahydrogeneted menaquinones with eight isoprene units [MK-8(H_4)] predominate in *Planomonospora venezuelensis* (Collins et al., 1984). In *Planomonospora alba* and *Planomonospora sphaerica*, the major menaquinone detected was MK-9(H_2), though minor amounts of MK-9(H_4) were also present (Mertz, 1994).

The phospholipids of *Planomonospora parontospora* consist of phosphatidylinositol, phosphatidylethanolamine, unknown glucoseamine-containing phospholipids, and diphosphatidylglycerol (DPG) plus lyso-DPG (Hasegawa et al., 1979). The phospholipids present in *Planomonospora alba* and *Planomonospora sphaerica* are diphosphatidylglycerol, phosphatidylglycerol, phosphatidylethanolamine, hydroxyphosphatidylethanolamine, and glucoseamine-containing phospholipids (Mertz, 1994). These polar lipid patterns correspond to phospholipid type IV of Lechevalier et al. (1981).

Planomonospora parontospora and *Planomonospora venezuelensis* have saturated and unsaturated fatty acids; the presence of C_{16} iso and $C_{15/17}$ iso branched fatty acids is variable, but $C_{15/17}$ anteiso is not present (Kroppenstedt, 1985). The presence of 10-methyl branched fatty acids has been demonstrated (Kroppenstedt, 1985; Kroppenstedt and Kutzner, 1978). Differences in fatty acid patterns can be used as diagnostic characteristics for the identification of *Planomonospora* species (Mertz, 1994; Table 290).

Colony morphology. Colonies on agar media are flat or elevated with smooth surfaces, but are occasionally wrinkled or slightly crustose. Abundant aerial mycelium is observed on a few media such as oatmeal agar for *Planomonospora parontospora* (Thiemann et al., 1967) and ATCC medium 172 for *Planomonospora alba* and *Planomonospora sphaerica* (Mertz, 1994). Good or moderately developed aerial mycelium can be observed on Czapek, oatmeal (ISP medium 3), and inorganic salts-starch (ISP medium 4) and potato carrot agar for *Planomonospora alba* and *Planomonospora sphaerica*. In general, *Planomonospora parontospora* and *Planomonospora venezuelensis* develop aerial mycelium moderately or in traces. The color of the aerial mycelium is white with a rose tinge in *Planomonospora parontospora* (Thiemann, 1974b) and white or pink in *Planomonospora sphaerica* (Mertz, 1994). White or grayish white aerial mycelium is a characteristic

feature for *Planomonospora alba* (Mertz, 1994) and *Planomonospora venezuelensis* (Thiemann, 1974b).

The substrate mycelium of *Planomonospora parontospora* is light rose to rose color on oatmeal, skim milk, starch, and tyrosine agars. On Bennett's, potato plug, and nutrient agars, the color of the substrate mycelium is yellowish or creamish to light orange; on Hickey–Tresner and Czapek glucose agars it is hyaline (Thiemann et al., 1967, 1968a). The reverse color of colonies of *Planomonospora sphaerica* is pink on ATCC 172 and on ISP media 3 and 4 and on Czapek, potato-carrot, and tap water agars. The colonies of *Planomonospora alba* show grayish or yellow reverse color on these media (Mertz, 1994). The substrate mycelium of *Planomonospora venezuelensis* produces a violet color on oatmeal and skim milk agars and a brown-violet color on Bennett's, glucose-asparagine, Hickey–Tresner, starch, and yeast extract-malt extract agars. On nutrient agar, the color of the substrate mycelium is light brown, on potato plug agar it is gray, and it is hyaline on calcium malate, glycerol-asparagine and tyrosine agars (Thiemann, 1970).

The production of soluble pigments is restricted in *Planomonospora venezuelensis* to traces of a brown-violet pigment on oatmeal agar and an amber to brown pigment on Hickey–Tresner and glucose-asparagine agars (Thiemann, 1970). A very faint yellow pigment is formed by *Planomonospora parontospora* on oatmeal agar (Thiemann et al., 1967). *Planomonospora parontospora* subsp. *antibiotica* produces a light brown diffusible pigment on tyrosine agar (Thiemann et al., 1968a). *Planomonospora parontospora* subsp. *antibiotica* produces an antibacterial agent, sporangiomycin, under submerged conditions (Thiemann et al., 1968a). A protease inhibitor (antipain) has been isolated from a strain of *Planomonospora parontospora* (Wingender et al., 1975). The type strain of *Planomonospora sphaerica* produces a biological substance which has been identified as the antibiotic thiostrepton. The type strain of *Planomonospora alba* produces a biologically active agent against Gram-stain-positive bacteria and algae; it also exhibits antihelminthic activity and shows inhibition to bovine mastitis (Mertz, 1994).

Metabolism. *Planomonospora* species are aerobic, mesophilic to thermotolerant organisms, growing well on various complex and defined media (Mertz, 1994; Thiemann, 1974b). Their type strains can utilize a number of compounds as sole carbon sources, but in a broad distribution pattern (see Table 289). D-Glucose is used as a sole carbon source by all species.

Members of the genus *Planomonospora* grow at 20–40°C, with a temperature optimum at 28–37°C. *Planomonospora alba* can grow at 52°C (Mertz, 1994). Growth of *Planomonospora parontospora* is consistently good at 22–37°C (Goodfellow and Pirouz, 1982; Thiemann, 1974; Thiemann et al., 1967), but growth is not evident at 10°C. pH values from 6.0–9.0 are tolerated by all species, but growth does not occur at pH 5.0. *Planomonospora parontospora* grows sparsely at pH 6.0 and optimally at pH 7.0–8.0 (Goodfellow and Pirouz, 1982; Thiemann, 1974b; Thiemann et al., 1967). *Planomonospora alba* tolerates 2% (w/v) NaCl, *Planomonospora parontospora* subsp. *parontospora* and *Planomonospora venezuelensis* 3% (w/v) NaCl; only *Planomonospora parontospora* subsp. *antibiotica* is resistant to a concentration of 5% (w/v) NaCl (Mertz, 1994). The presence of lysozyme (0.005% w/v) is partially tolerated (Goodfellow and Pirouz, 1982).The type strains of *Planomonospora parontospora* and *Planomonospora venezuelensis* are sensitive to the antibiotics kanamycin, neomycin, and tobramycin, but are resistant to cephaloridine, lincomycin, novobiocin, rifampin, streptomycin, vancomycin, and penicillin. *Planomonospora venezuelensis* is sensitive to demethylchlortetracycline, but *Planomonospora parontospora* is not (Goodfellow and Pirouz, 1982). *Planomonospora alba* and *Planomonospora sphaerica* are resistant to 2.0 μg of kasugamycin per ml (Mertz, 1994). Further physiological features and degradation abilities are shown in Table 289.

Ecology. Members of the genus *Planomonospora* have a worldwide distribution in temperate, arid, and tropical soils. Thiemann (1970, 1974b) isolated 42 strains from 10 out of 454 soil samples (pH values 5.3–7.8) from Argentina, Chile, India, Italy, Peru, and Venezuela. A further 35 strains were isolated by D. Schäfer (personal communication) from soil samples collected in Ceylon, Egypt, France, Greece, Italy, Mexico, Namibia, Turkey, and the United States (Arizona, Florida, and Texas). The type strains of *Planomonospora sphaerica* and *Planomonospora alba* were isolated from soil collected in India and the Sudan, respectively (Mertz, 1994). Suzuki (2001) reported on the distribution of *Planomonospora* strains in 1200 soil samples collected from 28 countries. Strains of the *Planomonospora parontospora* group were present in 10.9% of the samples from 14 countries. Strains of the *Planomonospora venezuelensis* group were less frequently found and were detected only in 13 samples (1.1%). The latter were collected in tropical or temperate areas of Bolivia, Cyprus, Egypt, Greece, India, Japan, New Caledonia, and Turkey. Nearly all strains of *Planomonospora* (94%) were isolated from neutral to slightly alkaline (pH 7.0–9.0) soil samples (Suzuki et al., 2001b).

Enrichment and isolation procedures

Strains of *Planomonospora* can be enriched from soil by using the baiting technique described by Couch (1954) and Bland and Couch (1981). The soil sample (0.5–1.0 g) is placed into a small sterile Petri dish (4 cm diameter) and flooded with sterile distilled water, up to half the level of the dish, so that the material is well covered. After careful stirring, the soil particles are allowed to sediment. The addition of a very small trace of Tween can be helpful. Natural floating baits like pollen grains of *Pinus* (Schäfer, 1973) or grass blades (Mertz, 1994) are exposed on the surface of the water. Enrichment cultures are incubated in darkness at room temperature and examined after 2 and 4 weeks with a dissecting microscope at high magnification (60×). Typical sporangial bundles, i.e. sporangia on sporangiophores in double rows or in palm leaf pattern, can be picked up with a sterile thin pointed needle (Vobis, 1991) and placed onto the surface of an appropriate agar medium such as artificial soil agar (Henssen and Schäfer, 1971). This medium is transparent and promotes the production of aerial mycelium and sporangial development, thereby allowing the detection and examination of new isolates under the microscope (Cross, 1989). Young colonies can be transferred into slant culture tubes containing nutrient rich agar medium.

A new selective isolation technique developed by Suzuki et al. (2001b) employed a humic acid trace salts gellan gum medium (pH 9.0). A combination of the antimicrobial agents ampicillin (2 μg/ml), enoxacin (20 μg/ml), nalidixic acid, and trimethoprim may be added (Suzuki, 2001). The soil samples can be pretreated by dry heat with 100°C for 60 min (Suzuki, 2001). By using a flooding solution containing 0.1% skim milk in 5 mM *N*-cyclohexyl-2-amino-ethanesulfonic acid buffer

(pH 9.0), high yields of motile spores may be obtained. The flooded soil samples are incubated at 32°C for 90 min, centrifuged at 100 × g for 10 min, and further incubated at 32°C for 60 min after centrifugation (Suzuki et al., 2001b).

Strains of *Planomonospora* can be detected on isolation plates once micromonosporae and streptomycetes have been removed by using a battery of phages (Kurtböke, 2003).

Maintenance procedures

Cultures on agar slants can be stored at room temperature for several weeks. Long-term preservation can be achieved by using procedures recommended for aerobic actinomycetes.

Differentiation of the genus *Planomonospora* from other genera

Planomonospora is related to other genera with cell-wall chemotype III in the family *Streptosporangiaceae*. With the exception of *Herbidospora* Kudo et al. 1993, all of the strains classified in this family produce spores on aerial mycelia, but the sporulation types are highly variable and can be used to differentiate *Planomonospora* from the other genera. All *Planomonospora* strains form zoospores within sporangia. In contrast, the genera *Herbidospora*, *Microbispora*, *Microtetraspora*, and *Nonomuraea* produce nonmotile spores in bisporous, tetrasporous, or oligosporous chains.

The shape of sporangia and the number of spores are of diagnostic value. *Acrosporospora*, *Sphaerisporangium*, and *Streptosporangium* produce spherical and/or club-shaped sporangia which contain numerous nonmotile spores (see Table 275, family *Streptosporangiaceae*), whereas *Planobispora* and *Planotetraspora* strains form cylindrical sporangia which encase 2 and 4 zoospores, respectively (Runmao et al., 1993; Thiemann, 1970; Thiemann and Beretta, 1968). The sporangia of *Planomonospora* are also cylindrical, but each sporangium contains only a single motile spore. The sporangia of this organism are arranged either in parallel double rows (Figure 386) or in a palm leaf pattern (Figure 385), configurations that are unique among sporangia-forming actinomycetes.

Taxonomic comments

Most of the genera classified in the aggregated group "maduromycetes" (Goodfellow, 1989a), including the genus *Planomonospora*, were assigned to the family *Streptosporangiaceae* (Goodfellow et al., 1990b, 1992). Ward-Rainey et al. (1997) emended the description of the family and included six genera in it. The inclusion of the genera *Herbidospora*, *Microbispora*, *Microtetraspora*, *Planobispora*, *Planomonospora*, and *Streptosporangium* in the family was underpinned by Miyadoh et al. (1997). Subsequently, the genera *Acrocarpospora*, *Nonomuraea*, *Planotetraspora*, and *Sphaerisporangium* corrig. were added to the family (Ara and Kudo, 2007; Miyadoh et al., 2001).

Differentiation of species of the genus *Planomonospora*

Planomonospora species can be distinguished by the morphological arrangement of their sporangia (Figure 385 and Figure 386), by their menaquinone (Collins et al., 1984; Mertz, 1994) and fatty acid composition (Mertz, 1994), and by the characteristic color of the mycelium (Mertz, 1994; Thiemann, 1974b). The diagnostic characteristics of the four species are shown in Table 290. Additional differences are given in Table 289 and in the species descriptions.

List of species of the genus *Planomonospora*

1. **Planomonospora parontospora** Thiemann, Pagani and Beretta 1967, 29[AL]

pa.ron.to.spo′ra. Gr. v. *pareimi* to be by or near one, to be side by side; Gr. n. *spora* a seed, and in biology a spore; N.L. n. *parontospora* (nominative in apposition) spores side by side.

The hyphae of the substrate mycelium (0.6–0.8 µm in diameter) are occasionally branched, septated, and twisted, frequently with swellings. The substrate mycelium is rose to light orange in color. The hyphae of the aerial mycelium (1.0 µm in diameter) are sparsely branched. The aerial mycelium is whitish, always with a light rose tinge, and is abundant on oatmeal, Hickey–Tresner, and soil agars. Growth is very good on Bennett's, Hickey–Tresner, oatmeal, and glucose-asparagine agars.

Monosporous sporangia, developed only on aerial hyphae, are arranged in double parallel rows attached directly to a characteristically bent sporangiophore. Mature sporangia are cylindrical, 1.5 µm × 3.5–4.5 µm. Sporangiospores are motile, fusiform, and slightly curved, measuring 1.0–1.5 × 3.5–4.5 µm. The surfaces of the colonies are smooth, with abundantly to sparsely developed aerial mycelium. Moderate growth occurs on Czapek-glucose, nutrient, and soil agars, but growth is poor on glycerol-asparagine, skim milk, starch, and tyrosine agars. Growth is not apparent on calcium malate, cellulose, or peptone-iron agars.

Melanoid pigments are not produced; litmus milk is peptonized; gelatin is not liquified. Growth occurs at 22–37°C; pH optimum of 7.0–8.0.

DNA G+C content (mol%): 72 (T_m).

Type strain: ATCC 23863, DSM 43177, JCM 3093, NBRC 13880, NRRL B-8120, VKM Ac-664.

Sequence accession no. (16S rRNA gene): D85495.

1a. **Planomonospora parontospora subsp. parontospora** Thiemann, Pagani and Beretta 1967, 29[AL]

The subspecies description is the same as for the species.

DNA G+C content (mol%): 72 (T_m).

Type strain: ATCC 23863, DSM 43177, JCM 3093, NBRC 13880, NRRL B-8120, VKM Ac-664.

Sequence accession no. (16S rRNA gene): D85495.

1b. **Planomonospora parontospora subsp. antibiotica** Thiemann, Coronelli, Pagani, Beretta, Tamoni and Arioli 1968a, 528[AL]

an.ti.bi.o′ti.ca. N.L. fem. adj. *antibioticus* (from Gr. prep. *anti* against; Gr. n. *bios* life; L. suff. *-ticus -a -um* suffix of various meanings, but signifying in general made of or belonging to) related to antibiotic, intended to mean producing antibiotic.

Description as for the species. Good growth occurs on inorganic salts-starch and nutrient agars. A light brown diffusible melanoid pigment is formed on tyrosine agar. Gelatin is liquified, litmus milk is not peptonized, and tyrosine is degraded. H_2S is produced.

Produces the antibiotic sporangiomycin.

DNA G+C content (mol%): not determined.

Type strain: ATCC 23864, DSM 43869, JCM 3094, NBRC 15869.

Sequence accession no. (16S rRNA gene): AB028653.

2. **Planomonospora alba** Mertz 1994, 280VP

al′ba. L. fem. adj. *alba* white, referring to the white aerial hyphae.

The hyphae of the substrate mycelium do not fragment and are about 1.0 µm in diameter. Substrate mycelium varies from whitish to yellowish-gray in color. The aerial mycelium is white, and abundant on ATCC medium 172. Aerial hyphae have a diameter of 1.0 µm.

Sporangiophores with long double rows of cylindrical sporangia. Each sporangium contains a single cylindrical to obclavate spore. Spores become motile after 30–60 min immersion in water and are liberated from the sporangial envelope. The mean spore size is 4.4 × 1.5 µm (range 3.5–5.4 × 1.4–1.6 µm).

Abundant growth on ATCC medium 172 and on inorganic salts-starch agar (ISP medium 4); good growth on Aino Henssen agar, Czapek agar, and oatmeal agar (ISP medium 3); and fair growth on potato-carrot agar and tap water agar. Soluble pigments are not produced. Grows at temperatures 20–50°C, tolerates NaCl only at a concentration of 2%, w/v, but is resistant to 2.0 µg of kasugamycin per ml.

Shows biological activity against Gram-stain-positive microorganisms and algae, exhibits antihelminthic activity, and is inhibitory to bovine mastitis.

DNA G+C content (mol%): not determined.

Type strain: A82600, ATCC 51588, DSM 44227, JCM 9373, NRRL 18924.

Sequence accession no. (16S rRNA gene): AB062381.

3. **Planomonospora sphaerica** Mertz 1994, 278VP

spha.e′ri.ca. L. fem. adj. *sphaerica* spherical, referring to the presence of spherical bodies.

Hyphae of the substrate mycelium do not fragment and have a diameter of 1.0 µm. The substrate mycelium is yellowish-pink or pink to a distinctive reddish orange color. The aerial mycelium is pink, but is sometimes white, and is abundant on ATCC medium 172.

Aerial hyphae produce sporangiophores bearing double rows of cylindrical sporangia arranged in parallel. Each sporangium contains a single spore which is released after immersed in water for 30–60 min. Spores are cylindrical to subclavate, mean size 4.4 × 1.5 µm (range 3.5–5.4 × 1.4–1.6 µm), and are motile by flagella. Large spherical bodies are formed on inorganic salts-starch agar. These spherical bodies have the capacity to germinate, forming promycelia.

Growth is abundant on ATCC medium 172 and inorganic salts-starch agar (ISP medium 4); good on Aino Henssen agar, Czapek agar, and potato-carrot agar; and fair on tap water agar. Soluble pigments are not produced. Grows at temperatures of 20–42°C; NaCl is tolerated at a concentration of 2%, w/v; is resistant to 2.0 µg of kasugamycin per ml.

Produces the antibiotic thiostrepton.

DNA G+C content (mol%): not determined.

Type strain: A51460, ATCC 51587, DSM 44632, JCM 9374, NRRL 18923.

Sequence accession no. (16S rRNA gene): AB062382.

4. **Planomonospora venezuelensis** Thiemann 1970, 247AL

ve.ne.zu.e.len′sis. N.L. fem. adj. *venezuelensis* of or pertaining to Venezuela.

Hyphae of the substrate mycelium are 1.0 µm in diameter and are frequently branched and septate. Substrate mycelium is violet-brown on most agar media. The color of the aerial mycelium is white to grayish white. Aerial hyphae (0.5–0.6 µm in diameter) are sparsely branched, long, wavy, and slender.

Monosporous sporangia are developed at the tips of aerial hyphae, alternately on very short lateral ramifications, arranged in two rows on opposite sides, i.e. in a “palm leaf pattern”. Occasionally, sporangia can be produced singly. Sporangia are cylindrical to clavate, 1.0 µm × 4.5–5.5 µm, and are formed abundantly on Hickey–Tresner agar. Spores are motile, fusiform, measuring 1.0 µm in diameter and 3.0–3.5 µm in length.

Good growth on complex media like Bennett’s agar, yeast extract-malt extract, nutrient and potato plug agars. Moderate growth on glycerol-asparagine, oatmeal, skim milk, and tyrosine agars. Optimum temperature for growth is 28–37°C. Traces of a brown-violet soluble pigment are produced on oatmeal agar, and an amber to amber-brown pigment on Bennett’s and Hickey–Tresner agars. Gelatin stabs are scarcely liquified.

DNA G+C content (mol%): not determined.

Type strain: ATCC 23865, DSM 43178, JCM 3167, NBRC 15590, NRRL B-16603, VKM Ac-699.

Sequence accession no. (16S rRNA gene): AB028655.

Genus IX. **Planotetraspora** Runmao, Guizhen and Junying 1993, 468VP emend. Tamura and Sakane 2004, 2055

Zhi-Heng Liu

Pla.no.te.tra. spo′ra. Gr. n. *planos* wanderer; Gr. adj. *tetra* four; Gr. n. *spora* a seed; N.L. fem. n. *Planotetraspora* four-spored organism.

Aerobic, Gram-stain-positive, non-acid-fast actinomycete which forms a branching, nonfragmenting substrate mycelium. **Long, cylindrical sporangia are formed at the ends of short sporangiophores on aerial hyphae. Each sporangium contains a row of four spores which may be cylindrical, oval, or rod-shaped** (0.4–1.4 × 0.8–1.5 µm), and may be motile. Vegetative hyphae tend to be pale yellow to white. Good growth occurs at 25–30°C. Cell walls contain *meso*-diaminopimelic acid, alanine, and glutamic

acid. The peptidoglycan type is A1γ. Muramic acid moieties are *N*-acetylated. Madurose and rhamnose are present in whole-organism hydrolysates. **The major menaquinone is MK-9(H_4), the predominant fatty acid is $C_{18:0}$ 10-methyl, and the diagnostic phospholipid is phosphatidylethanolamine**. Does not contain mycolic acids. Habitat is soil. The phylogenetic position of *Planotetraspora*, as determined by 16S rRNA gene sequence analysis, is in the family *Streptosporangiaceae*.

DNA G+C content (mol%): 71.

Type species: **Planotetraspora mira** Runmao, Guizhen and Junying 1993, 468[VP].

Further descriptive information

The genus *Planotetraspora* contains two species, *Planotetraspora mira* and *Planotetraspora silvatica*, which form a distinct 16S rRNA gene clade within the evolutionary variation encompassed by the family *Streptosporangiaceae*. The closest phylogenetic neighbors of the taxon are the genera *Acrocarpospora* (95.8–97.1%) and *Herbidospora* (95.8–97.1% similarity; Tamura and Sakane, 2004). These workers also found that the type strains of these species share DNA–DNA relatedness levels within the range 38–42%.

Runmao et al. (1993) reported that whole-organism hydrolysates of *Planotetraspora mira* contain arabinose, galactose, mannose, ribose, and xylose, but this was not confirmed in subsequent studies where only madurose and rhamnose were detected as whole-organism sugars (Kudo, 2001; Tamura and Sakane, 2004). In contrast, whole-organism hydrolysates of *Planotetraspora silvatica* NBRC 10041[T] contain galactose, glucose, madurose, 3-*O*-methylmannose, and rhamnose (Tamura and Sakane, 2004).

Planotetraspora mira NBRC 15435[T] grows well and produces aerial mycelia and sporangia on HV agar (Hayakawa and Nonomura, 1989) and on yeast extract-malt extract, oatmeal, inorganic salts-starch, and glycerol-asparagine agars (ISP media 2, 3, 4, and 5, respectively; Shirling and Gottlieb, 1966). The type strain of *Planotetraspora silvatica* also shows good growth on glycerol-asparagine and yeast extract-malt extract agars, and on tyrosine agar (ISP medium 7; Shirling and Gottlieb, 1966).

Enrichment and isolation procedures

The type strain of *Planotetraspora silvatica* was isolated from a sample of forest soil collected from Amami island, Kagashima Prefecture, Japan. The organism was isolated on HV agar (Hayakawa and Nonomura, 1987b) following treatment of the initial dilution with yeast extract and sodium dodecyl sulfate (Hayakawa and Nonomura, 1989). Details were not given on how the *Planotetraspora mira* strains were recovered from a soil sample collected from Wolung village, Sichuan, China (Runmao et al., 1993).

TABLE 291. Phenotypic properties which distinguish between the type strains of *Planotetraspora mira* and *Planotetraspora silvatica*[a,b]

Characteristic	*P. mira* NBRC 15435[T]	*P. silvatica* NBRC 10041[T]
Color of colonies on yeast extract-malt extract agar	White	Yellow
Spores motile	+	−
Acid from:		
Lactose	+	−
Mannitol	+	−
Mannose	+	−
Rhamnose	+	−
Decomposition of:		
Starch	+	+
Xanthine	−	−
Growth on sole carbon sources:		
Glucose	+	−
Mannitol	+	−
Melibiose	−	+
Raffinose	−	+
Xylose	+	−

[a]Symbols: +, >85% positive; −, 0–15% positive.

[b]Data taken from Runmao et al. (1993) and Tamura and Sakane (2004).

Maintenance procedures

Working cultures can be maintained on appropriate standard media such as glucose-asparagine, oatmeal, and yeast extract-malt extract agars. Long-term preservation of strains can be achieved as frozen stocks at −20°C or by using standard lyophilization procedures.

Differentiation of the genus *Planotetraspora* from other genera

Planotetraspora strains can be distinguished from the other genera classified in the family *Streptosporangiaceae* by using a combination of chemotaxonomic and morphological properties (see Table 291 section on the family *Streptosporangiaceae*), notably by their ability to form sporangia which contain a row of four spores. The type strains of the two species form a distinct line of descent within the 16S rRNA *Streptosporangiaceae* gene tree. The signature nucleotides of the 16S rRNA genes of these organisms at positions 502:543 (A–U) and 116:1184 (U–G) are different from those of other members of the family [positions 502:543 (G–C), 1116:1184 (C–G)].

Differentiation of species of the genus *Planotetraspora*

The type strains of *Planotetraspora mira* and *Planotetraspora silvatica* can be distinguished by using a combination of phenotypic properties (Table 291).

List of species of the genus *Planotetraspora*

1. **Planotetraspora mira** Runmao, Guizhen and Jungying 1993, 468[VP]

mi′ra. L. fem. adj. *mira* extraordinary, marvellous.

Forms irregular branching substrate hyphae (0.3–0.6 µm in width) and sparsely branched aerial hyphae (0.2–0.4 µm in width). Cylindrical to clavate sporangia (~2.1–2.7 × 0.6–0.9 µm) are produced on the aerial mycelium either singly or in groups, especially on oatmeal agar; the sporangia are borne on short sporangiophores (0.2–0.8 µm long). Transverse septa divide each sporangium into four spores which at maturity are either cylindrical or spherical (0.8–1.4 × 0.4–0.6 µm). Thirty minutes after being released from the sporangia,

spores become motile by means of polar flagella. The sporangiospores are covered by a thin sporangial wall which is readily seen by transmission electron microscopy, but not by light microscopy. Good growth occurs between 28–37°C, and from pH6.0–8.0.

Milk is slowly peptonized and coagulated.

Little or doubtful growth is observed with L-arabitol, L-arabinose, dulcitol, galactose, inulin, maltose, melezitose, rhamnose, D-ribose, salicin, sorbitol, sorbose, sucrose, and trehalose as sole carbon sources for energy and growth.

Additional phenotypic features are shown in Table 291.

Whole-organism hydrolysates contain madurose and rhamnose. Phosphatidylethanolamine is the diagnostic polar lipid. The predominant menaquinone is MK-9(H_4).

Source: a soil sample collected in Wolung village, Suchuan, China.

DNA G+C content (mol%): not determined.

Type strain: NA9211028, SIIA9201, ATCC 51423, DSM 44359, JCM 9131, NBRC 15435, VKM Ac-2000.

Sequence accession no. (16S rRNA gene): D85496.

Additional comment: the sporangia have been considered to have warty surfaces (Runmao et al., 1993).

2. **Planotetraspora silvatica** Tamura and Sakane 2004, 2055[VP]

sil.va′ti.ca. L. fem. adj. *silvatica* of or belonging to a wood.

Forms an extensively branched substrate mycelium and an aerial mycelium. Long cylindrical sporangia are formed at the ends of short sporangiophores borne on aerial hyphae. Each sporangium contains a single row of oval to rod-shaped spores (0.4–1.4 × 0.8–1.5 µm). A brownish soluble pigment is formed on tyrosine agar (ISP medium 7). The optimal temperature for growth is 25–30°C; growth does not occur at 37°C.

Milk is peptonized and coagulated. Gelatin hydrolysis is negative or weakly positive. Does not degrade calcium malate, or grow in the presence of 4% NaCl.

Galactose, lactose, maltose, melibiose, α-methyl-D-glucoside, and rhamnose are used as sole carbon sources for energy and growth, but adonitol, arabinose, dulcitol, and erythritol are not.

Additional phenotypic features are shown in Table 291.

Muramic acid moieties are *N*-acetylated. Whole-organism hydrolysates contain galactose, glucose, madurose, α-O-methylmannose, and rhamnose. The major fatty acids are $C_{18:0}$ 10 methyl and $C_{16:0}$ iso (>14%). Does not contain mycolic acids. Phosphatidylethanolamine and an unidentified phospholipid containing glucosamine are the diagnostic polar lipids. The predominant menaquinone is MK-9(H_4).

Source: a forest soil in Amami Island, Kagashima Prefecture, Japan.

DNA G+C content (mol%): 71 (HPLC).

Type strain: TT 00-51, DSM 44746, JCM 12867, NBRC 100141.

Sequence accession no. (16S rRNA gene): AB112082.

Genus X. **Sphaerisporangium** Ara and Kudo 2007, 2449[VP] (Effective publication: Ara and Kudo 2007c, 18.)

Martha E. Trujillo, Lorena Carro and Michael Goodfellow

Spha.e.ri.spo.ran′gium. L. n. *sphaera* sphere; N.L. neut. n. *sporangium* sporangia; N.L. neut. n. *Sphaerisporangium* an organism with spherical sporangia.

Aerobic, non-acid-fast, Gram-stain-positive actinomycetes which form branched, non-fragmenting substrate and aerial hyphae. **Single or clustered spherical spore vesicles (~1.5–8.0 µm) are produced on aerial hyphae**. **Vesicles contain coiled chains of non-motile spores which are oval or spherical (0.4–0.9 × 0.6–1.2 µm) with smooth, wrinkled, and prominently ridged surfaces**. Chemo-organotrophic with an oxidative type of metabolism. **The cell wall contains *meso*-diaminopimelic acid. Whole-cell hydrolysates contain galactose, glucose, madurose, mannose, and ribose. The diagnostic phospholipids are phosphatidylethanolamine and ninhydrin-positive phosphoglycolipids. The major fatty acids are $C_{16:0}$ iso and 10-methyl $C_{17:0}$, and the predominant menaquinones, MK-9(H_4) and MK-9(H_6). Phylogenetically related to members of the family *Streptosporangiaceae*.**

DNA G+C content (mol%): 67–72 (HPLC).

Type species: **Sphaerisporangium melleum** corrig. Ara and Kudo 2007c, 2449[VP].

Further descriptive information

Phylogeny. The genus *Sphaerisporangium* forms an independent phyletic branch in the *Streptosporangiaceae* 16S rRNA gene tree (See Figure 360). The species *Thermopolyspora flexuosa* (94.4% sequence similarity) appears to be the closest phylogenetic neighbor forming a deep branch next to *Sphaerisporangium*. The six constituent species form a clade supported by a bootstrap value of 90% (Figure 387). 16S rRNA gene sequence similarity between the six species is 96.3–97.6% and DNA–DNA hybridization values are 32–66% (Cao et al., 2009).

Cell morphology. *Sphaerisporangium* strains form non-fragmenting substrate mycelia and branched aerial hyphae which carry single or clustered spherical spore vesicles (~1.5–8.0 µm) (Figure 388). Spores are nonmotile and are usually formed by the separation of unbranched hyphae within spore vesicles. Spores may be oval, spherical, or pyriform with smooth, wrinkled, and ridged surfaces.

Nutrition and growth conditions. *Sphaerisporangium* strains grow well on standard complex media including Bennett's agar (Jones, 1949), glucose-yeast extract agar (Gordon and Mihm, 1962), oatmeal agar (ISP 3 medium) (Shirling and Gottlieb, 1966), and yeast extract-malt agar (ISP 2 medium). Moderate growth has been observed on glucose-asparagine agar and Hickey–Tresner agar (Hickey and Tresner, 1952), oatmeal-nitrate agar and 1/5 yeast-starch agar. Growth is poor on Czapek's agar (Pridham and Lyons, 1980), glycerol-asparagine agar (ISP 5 medium) (Shirling and Gottlieb, 1966), inorganic salt-starch agar (ISP 4) (Shirling and Gottlieb, 1966), and nutrient agar. All strains are strictly aerobic and chemo-organotrophic with an oxidative metabolism. Most species grow well between 20–37°C and pH 5–9. *Sphaerisporangium cinnabarinum* produces a bright red diffusible pigment.

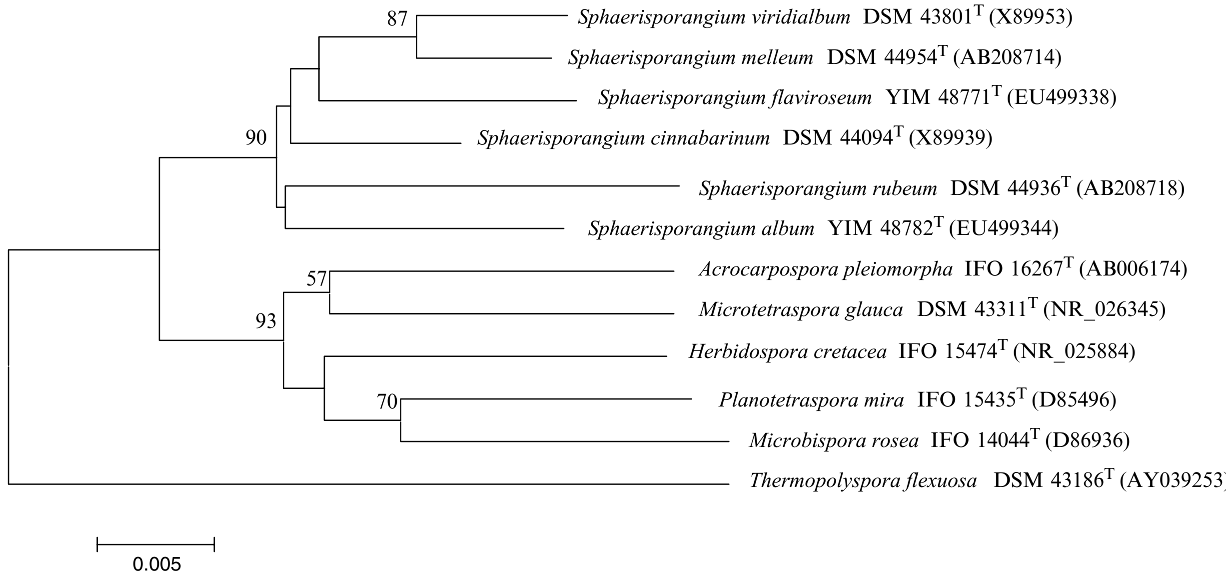

FIGURE 387. Neighbor-joining tree generated from 16S rRNA gene sequences showing relationships between *Sphaerisporangium* species and related taxa. Evolutionary distances were calculated using the Kimura 2-parameter method (Kimura, 1980). Bootstrap values indicated at branching points are expressed as percentages of 1000 replications (only values greater than 50% are shown). Bar = 0.5% sequence divergence.

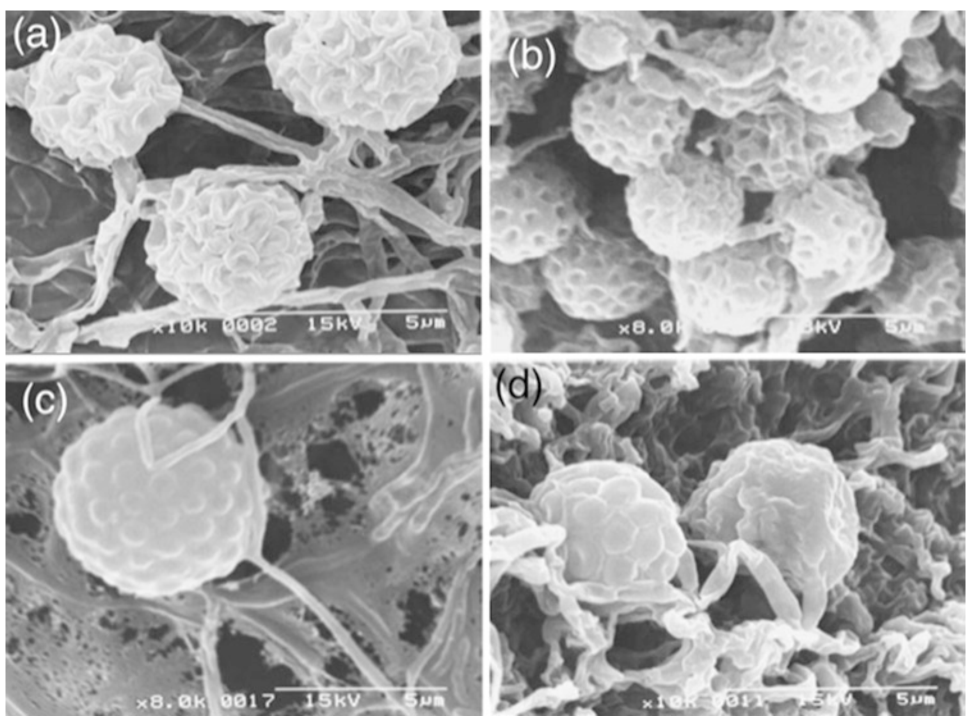

FIGURE 388. Scanning electron micrographs of globose sporangia on aerial mycelia of (a) *Sphaerisporangium melleum* 3-28(8)^{T}; (b) *Sphaerisporangium rubeum* 3D-73(35)^{T}; (c) *Sphaerisporangium cinnabarinum* JCM 3291^{T}, and (d) *Sphaerisporangium viridialbum* JCM 3027^{T} grown on oatmeal-nitrate agar for 21 d at 30°C. (Reproduced with permission from I. Ara and T. Kudo. Society for Actinomycetes, Japan.)

Cell-wall composition. *Sphaerisporangium* species contain *meso*-diaminopimelic acid (*meso*-A_2pm) as the major wall diamino acid and galactose, glucose, madurose, mannose, and ribose which corresponds to a whole-cell sugar pattern B (Lechevalier and Lechevalier, 1970b). The diagnostic sugar madurose is also found in other genera, including *Actinomadura*, *Dermatophilus*, *Microbispora*, *Planobispora*, *Planomonospora*, *Spirillospora*, and *Streptosporangium*. The major phospholipids are

diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, phosphatidylinositol mannoside, and ninhydrin-positive phosphoglycolipids mannosides. This pattern corresponds to a phospholipid type IV profile (Lechevalier et al., 1981).

The distribution of menaquinones in the genus *Sphaerisporangium* is rather complex. *Sphaerisporangium cinnabarinum*, *Sphaerisporangium melleum*, *Sphaerisporangium rubeum*, and *Sphaerisporangium viridialbum* contain major amounts of MK-9(H_4) and MK-9(H_6) and small amounts of MK-9(H_2), MK-9(H_0), and MK-9(H_8) (Ara and Kudo, 2007). In the case of *Sphaerisporangium flaviroseum* and *Sphaerisporangium album*, the predominant menaquinones are MK-9(H_4), MK-9(H_2), and MK-9, accounting for ~90% of the total composition (Cao et al., 2009). The MK-9 component in these species is 28.1 and 29.0%, respectively; the remaining *Sphaerisporangium* species contain less than 10% of this molecule. Tetrahydrogenation of the menaquinones occurs at sites of isoprene unit III (the third unit from the 2-methyl-1,4–naphthoquinone moiety) and VIII [MK-9(III, VII-H_4)] (Ara and Kudo, 2007).

The major cellular fatty acids are $C_{16:0}$ iso and $C_{17:0}$ 10-methyl with smaller amounts of the saturated, unsaturated, branched and 10-methyl fatty acids, a profile which corresponds to type 3c after Kroppenstedt (1985). Mycolic acids are absent.

Ecology. The primary habitat of *Sphaerisporangium* strains appears to be soil. *Sphaerisporangium album*, *Sphaerisporangium cinnabarinum*, *Sphaerisporangium flaviroseum*, *Sphaerisporangium melleum*, and *Sphaerisporangium rubeum* have been isolated from this source, and *Sphaerisporangium viridialbum*, from acidic volcanic ash. Janso and Carter (2010) found that 19% of 123 endophytic actinomycetes isolated from tropical plants collected from several locations in Papua New Guinea and Mborokua Island (Solomon Islands), belonged to the *Sphaerisporangium* 16S RNA gene tree suggesting that plants, specifically roots, may be a natural habitat for these micro-organisms.

Isolation procedure. Humic acid-vitamin agar (Hayakawa and Nonomura, 1987b) supplemented with cycloheximide (50 mg/ml), nystatin (50 mg/ml), and nalidixic acid was used for the isolation of several *Sphaerisporangium* species using the dilution plate method (Ara and Kudo, 2007). Isolation plates were incubated under aerobic conditions for 21 d at 30°C. *Sphaerisporangium album* and *Sphaerisporangium flaviroseum* were isolated on glycerol-asparagine agar [per liter: glycerol, 10 g; asparagine, 1 g; $K_2HPO_4 \cdot H_2O$, 1 g; $MgSO_4 \cdot 7H_2O$, 0.5 g; $CaCO_3$, 0.3 g; vitamin mixture powder, 3.7 mg (Hayakawa and Nonomura, 1987b); potassium dichromate, 50 mg; agar, 20 g].

Janso and Carter (2010) isolated endophytic *Sphaerisporangium* strains from stems, roots, and leaves by cutting them into pieces using pruning shears or a scalpel following removal of soil and organic debris by rinsing them thoroughly under running tap water. The tissues were successively cut into 2- by 2-mm pieces with a scalpel, placed inside a tea strainer, and immersed in a series of solutions for surface sterilization. Thin or herbaceous tissues (such as leaves, stems, and petioles), were treated with 70% ethanol for 1 min, 50% Clorox bleach (approx. 3% NaOCl) for 3 min, and 70% ethanol for 0.5 min followed by a rinse in sterile water. The procedure was the same for thicker or woody tissues, such as roots and twigs, except that they were immersed in 50% bleach for 5 min. Tissue samples were aseptically transferred to the surface of arginine-vitamin agar (Nonomura and Ohara, 1969a) supplemented with 3% soil extract (Hayakawa et al., 2000) and cycloheximide (100 μg/ml) and nystatin (50 μg/ml). The soil extract was prepared by mixing 100.0 g organic humus (Jolly Gardener Products Inc., Poland, ME) in 100 ml of tap water; the suspension was autoclaved at 121°C for 30 min, transferred to a 1-liter centrifuge bottle, and centrifuged at 4000 r.p.m. for 20 min. The supernatant was filtered through a 0.2-μm cellulose nitrate filter unit (Nalgene). Inoculated Petri dishes were incubated at room temperature (approx. 23–25°C) for up to 8 weeks.

Maintenance procedures

Sphaerisporangium strains can be maintained on yeast-starch agar [per liter: soluble starch, 15.0 g; yeast extract, 4.0 g; $K_2HPO_4 \cdot 7H_2O$, 0.5 g; agar 15.0 g; (pH 7.2)] or ISP 2 agar (Shirling and Gottlieb, 1966) at 4°C for short-term preservation; mycelial fragments in 20% glycerol (v/v) can be maintained at −25°C. Long-term storage can be achieved by lyophilization.

Differentiation of the genus *Sphaerisporangium* from other genera

16S rRNA gene sequencing and the presence of specific signature nucleotides at position 263 (G), 264 (U), 595 (G), 600:638 (U–G), 602:636 (C–G), 603:635 (C–G), 627 (G), 626 (U), 625 (G), 668:738 (C–G), 669:737 (A–U), 671:735 (G–C), 1012:1017 (G–C), and 1263:1272 (G–U) clearly differentiate *Sphaerisporangium* from other genera classified in the family *Streptosporangiaceae* (Ara and Kudo, 2007). The genera *Herbidospora* and *Sphaerisporangium* can be readily distinguished by their menaquinone profiles.

Taxonomic comments

The genus *Sphaerisporangium* was proposed by Ara and Kudo (2007) to accommodate five strains isolated from soil. They also examined "*Streptosporangium cinnabarinum*" JCM 3291 and *Streptosporangium viridialbum* JCM 3027^T which, from the phylogenetic point of view, were considered to be moderately related to the genus *Streptosporangium* (Kemmerling et al., 1993; Tamura et al., 2000; Ward-Rainey et al., 1996). Ara and Kudo (2007) proposed three new species, *Sphaerosporangium melleum*, the type species, *Sphaerosporangium cinnabarinum*, and *Sphaerosporangium rubeum* and, in addition, transferred *Streptosporangium viridialbum* Nonomura and Ohara 1960, to the genus *Sphaerosporangium* as *Sphaerosporangium viridialbum* Nonomura and Ohara 1960 comb. nov. These taxa were included in Validation List no. 118, under the genus *Sphaerisporangium* corrig. as opposed to the earlier incorrect name *Sphaerosporangium* Ara and Kudo 2007. Two additional species, *Sphaerisporangium album* and *Sphaerisporangium flaviroseum*, were recognized by Cao et al. (2009) who also emended the description of the genus.

Differentiation of species of the genus *Sphaerisporangium*

Sphaerisporangium species can be distinguished from one another by using a combination of morphological, nutritional, and physiological characteristics (Table 292).

TABLE 292. Characteristics that differentiate the type strains of *Sphaerisporangium* species[a,b]

Characteristic	*S. melleum*	*S. album*	*S. cinnabarinum*	*S. flaviroseum*	*S. rubeum*	*S. viridialbum*

List of species of the genus *Sphaerisporangium*

1. **Sphaerisporangium melleum** corrig. Ara and Kudo 2007c, 2449[VP] (Effective publication: Ara and Kudo 2007, 19.)

mel′le.um. L. neut. adj. *melleum* honey-colored.

Branched, non-fragmenting, substrate and aerial hyphae are formed. The vegetative mycelium is light wheat to honey gold in color and the aerial mycelium is white. Spherical spore vesicles which carry coiled spore chains are formed on the aerial hyphae. Abundant sporulation is obtained on inorganic salts-starch, sucrose-nitrate, tap water, and 1/5 yeast extract-starch agars. Good growth is observed on Bennett's, oatmeal, and yeast extract-starch agars; moderate growth on glucose-asparagine, Hickey–Tresner, and 1/5 yeast extract-starch agars, and poor growth on glycerol-asparagine agar, inorganic salts-starch, nutrient, sucrose-nitrate, tap water and tyrosine agars. Diffusible pigments are not produced on these media. Glycerol, erythritol and *myo*-inositol are weakly utilized as sole carbon sources. Other physiological data are given in Table 292 together with information on menaquinone and fatty acid composition.

Source (type strain): soil collected in Bangladesh.

DNA G+C content (mol%): 71.0 (HPLC).

Type strain: 3-28(8), DSM 44954, JCM 13064.

Sequence accession no. (16S rRNA gene): AB208714.

2. **Sphaerisporangium album** Cao, Jiang, Xu, Jiang 2009, 1682[VP]

al′bum. L. neut. adj. *album* white.

Branched, non-fragmenting, substrate and aerial hyphae are formed. Pale-gray substrate and white aerial mycelia are produced. Spherical and pyriform spore vesicles are borne on aerial mycelia. Good growth is observed on oatmeal and yeast extract-malt extract agars, and moderate growth on Czapek's, glycerol-asparagine and inorganic salt-starch agars. Diffusible pigments are not produced on any of these media. Grows in the presence of 2% (w/v) NaCl. Catalase-positive. H_2S is not produced; milk is not coagulated or peptonized. Does not degrade cellulose. Alkaline phosphatase, esterase (C4), esterase lipase (C8), lipase (C14), leucine arylamidase, valine arylamidase, trypsin, α-chymotrypsin, acid phosphatase, naphthol-AS-BI-phosphohydrolase, β-galactosidase, α-glucosidase, β-glucosidase, *N*-acetyl-β-glucosaminidase, and α-mannosidase are produced but not cystine arylamidase, α-fucosidase, α-galactosidase, or β-glucuronidase. L-Arginine, histidine, lysine, ornithine, L-phenylalanine, proline, serine, L-valine, and urea are hydrolyzed, but not glycine, methionine, L-tryptophan, or xanthine. Other physiological data are given in Table 292 together with information on menaquinone and cellular fatty acid composition.

Source (type strain): soil samples collected from virgin forest at Jinbian Rivulet in Hunan Province, China.

DNA G+C content (mol%): 71 (HPLC).

Type strain: CCTCC AA 208026, DSM 45172, YIM 48782.

Sequence accession no. (16S rRNA gene): EU499344.

3. **Sphaerisporangium cinnabarinum** corrig. Ara and Kudo 2007c, 2449[VP] (Effective publication: Ara and Kudo 2007, 19.)

cin.na.ba'ri.num. L. n. *cinnabar -aris*, cinnabar; L. suff. *-inus -a -um*, suffix used with the sense of belonging to; N.L. neut. adj. *cinnabarinum* of cinnabar, referring to the vermilion (bright red) color of the vegetative mycelium and diffusible pigment.

Branched, non-fragmenting, substrate and aerial hyphae are formed. Substrate mycelium is light wheat to melon yellow. White aerial hyphae carry globose spore vesicles containing coiled spore chains. Spores are produced on humic acid-vitamin, oatmeal-nitrate and sucrose-nitrate agars. Good growth is observed on oatmeal and yeast extract-starch; moderate growth on Bennett's, glucose-asparagine, glucose-yeast extract, humic acid-vitamin, inorganic salts-starch, oatmeal-nitrate, and 1/5 yeast extract agars; growth is poor on glycerol-asparagine, Hickey–Tresner, nutrient, tap water, tyrosine, and yeast-extract malt extract agars. Use *myo*-inositol, α-methyl-D-glucoside, and α-D-melibiose as sole carbon sources. Other physiological data are given in Table 292 together with information on menaquinone and cellular fatty acid composition.

Source (type strain): soil collected in the Philippines.

DNA G+C content (mol%): 70 (HPLC).

Type strain: DSM 44094, JCM 3291.

Sequence accession no. (16S rRNA gene): X89939.

4. **Sphaerisporangium flaviroseum** Cao, Jiang, Xu and Jiang 2009, 1682[VP]

fla.vi.ro'se.um. L. adj. *flavus* yellow; L. adj *roseus* rose; N.L. neut. adj. *flaviroseum* yellowish-rose colored.

Branched, non-fragmenting, substrate and aerial hyphae are formed and a yellow-pink substrate and white aerial mycelia produced. Spherical and pyriform spore vesicles are borne on aerial mycelia. Good growth is observed on oatmeal yeast extract-malt extract agars; moderate growth on Czapek's, glycerol-asparagine and inorganic salts-starch agars, ISP 4 agar, and ISP 5 agar. Diffusible pigments are not produced on these media. Grows at pH 8 and in the presence of 1% (w/v) NaCl. Catalase is not produced. Gelatin liquefaction, milk coagulation and peptonization, and production of H_2S are negative. Cellulose is not degraded. Alkaline phosphatase, esterase (C4), esterase lipase (C8), leucine arylmidase, valine arylamidase, trypsin, α-chymotrypsin, acid phosphatase, naphthol-AS-BI-phosphohydrolase, β-galactosidase, α-glucosidase, β-glucosidase, *N*-acetyl-β-glucosaminidase, α-mannosidase, and α-fucosidase are produced, but not cystine arylamidase, α-galactosidase, β-glucuronidase, or lipase (C14) (API ZYM tests). L-Arginine, ornithine, L-phenylalanine, proline, serine, L-valine, and urea are hydrolyzed, but not glycine, histidine, lysine, methionine, L-tryptophan, or xanthine.

Source (type strain): soil collected from Tianzi Mountain in Hunan Province, China.

DNA G+C content (mol%): 67.1 (HPLC).

Type strain: DSM 45170, JCM 16908, KCTC 19393, YIM 48771.

Sequence accession no. (16S rRNA gene): EU499338.

5. **Sphaerisporangium rubeum** corrig. Ara and Kudo 2007c, 2449[VP] (Effective publication: Ara and Kudo 2007, 19.)

ru'be.um. L. neut. adj. *rubeum* red colored.

Branched, non-fragmenting, substrate and aerial hyphae are formed. The vegetative mycelium is light coral pink to coral red and the aerial mycelium is white. Spherical vesicles which carry coiled spore chains are formed on aerial hyphae. Good growth is obtained on yeast extract-starch agar, Bennett's, glucose-yeast extract, Hickey–Tresner, oatmeal and yeast extract-malt extract agars; moderate growth on humic acid-vitamin, inorganic salts-starch, nutrient agar, oatmeal-nitrate, and 1/5 yeast extract-starch agars; growth is poor on glucose-asparagine, glycerol-asparagine, sucrose-nitrate, tap water, and tyrosine agars. Scant sporulation occurs on humic acid-vitamin, oatmeal nitrate, sucrose-nitrate, and water agars.

Adonitol, erythritol, glycerol, and *myo*-inositol are weakly utilized as sole carbon sources. Other physiological data are given in Table 292 together with information on menaquinone and cellular fatty acid composition.

DNA G+C content (mol%): 71 (HPLC).

Type strain: 3D-72(35), DSM 44936, JCM 13067.

Sequence accession no. (16S rRNA gene): AB208718.

6. **Sphaerisporangium viridialbum** (Nonomura and Ohara 1960) corrig. Ara and Kudo 2007c, 2449[VP] (Effective publication: Ara and Kudo 2007, 19.)

vi.ri.di.al'bum. L. adj. *viridis* green; L. neut. adj. *album* white; N.L. neut. adj. *viridialbum* greenish white.

Branched, non-fragmenting, substrate and aerial hyphae are formed. Substrate mycelium is light wheat to bamboo yellow and the aerial mycelium is white. Spherical vesicles which carry coiled spore chains are formed on aerial hyphae. Sporulation occurs on Hickey–Tresner, humic acid-vitamin oatmeal-nitrate, sucrose-nitrate, and 1/5 yeast extract-starch agars. Grows well on Bennett's, glucose-yeast extract, Hickey–Tresner, oatmeal and yeast-extract-starch agars; moderate growth on humic acid-vitamin, nutrient, oatmeal-nitrate, yeast extract-malt extract, and 1/5 yeast extract-starch agars;

growth is poor on glucose-asparagine, glycerol-asparagine, inorganic salts-starch, sucrose-nitrate, tyrosine, and tap water agars. Glycerol and erythritol are weakly utilized as sole carbon sources. Other physiological data are given in Table 292 together with information on menaquinone and cellular fatty acid composition.

Source (type strain): acidic volcanic ash.

DNA G+C content (mol%): 72 (HPLC).

Type strain: ATCC 33328, CBS 432.61, DSM 43801, JCM 3027, KCC A-0027, KCTC 9435, NBRC 13987, NRRL B-2636, VKM Ac-679.

Sequence accession no. (16S rRNA gene): X89953.

Genus XI. **Thermopolyspora** (*ex* Krasil'nikov and Agre 1964) Goodfellow, Maldonado and Quintana 2005, 1980[VP]

Michael Goodfellow

Ther.mo.po.ly.spo′ra. Gr. n. *thermê* heat; Gr. adj. *polu* many; Gr. fem. n. *spora* a seed and, in bacteriology, a spore; N.L. fem. n. *Thermopolyspora* the heat (-loving) many-spored organism.

Aerobic, Gram-stain-positive, non-acid–alcohol-fast, actinomycete which forms non-fragmenting substrate and aerial mycelia. Hooked to irregular spiral chains of 4–10 warty to spiny ornamented spores (1.2–1.5 µm in diameter) are arranged in clusters on long, moderately branched aerial hyphae on potato carrot agar; a light blue aerial mycelium and a brown soluble pigment are also formed on this medium. White to yellowish-white aerial hyphae are borne on a light brown substrate mycelium on oatmeal agar, albeit without the production of diffusible pigments. **Grows from 40–60°C, and optimally between 45 and 55°C. Cell wall contains *meso*-diaminopimelic acid and *N*-acetylated muramic acid. Glucose and ribose are found in whole-organism hydrolysates. The predominant menaquinones are MK-9, MK-9(H_2), and MK-9(H_4), and the major polar lipids are phosphatidylethanolamine, hydroxyphosphatidylethanolamine, phosphatidylinositol mannosides, ninhydrin sugar-positive components, and uncharacterized glycolipids**. The organism is rich in saturated, unsaturated, and branched chain fatty acids, but does not contain mycolic acids. The phylogenetic position of *Thermopolyspora*, as determined by 16S rRNA gene sequence analysis, is in the family *Streptosporangiaceae.*

DNA G+C content (mol%): 77.

Type species: **Thermopolyspora flexuosa** (Meyer 1989) Goodfellow, Maldonado and Quintana 2005, 1982[VP] (*Actinomadura flexuosa* Meyer 1989, 2519).

Further descriptive information

Phylogeny. *Thermopolyspora flexuosa* DSM 43186[T] (formerly *Actinomadura flexuosa*) forms a distinct branch in the *Streptosporangiaceae* 16S rRNA gene tree (see Figure 360 in section on the family *Streptosporangiaceae*). Goodfellow et al. (2005) have shown that this strain produces the PCR product characteristic of members of the family *Streptosporangiaceae* when examined with the family-specific set of oligonucleotide primers developed by Monciardini et al. (2002).

Cell morphology. Strain DSM 43186[T] produces short curved chains of warty to spiny spores on potato carrot agar (Greiner-Mai et al., 1987).

Chemotaxonomy. A comprehensive survey of the chemotaxonomic properties of strain DSM 43186[T] was undertaken by Kroppenstedt et al. (1990a) who found that it produces whole-organism hydrolysates rich in ribose together with a trace of mannose. It also produces complex mixtures of saturated, unsaturated, and branched chain fatty acids and lacks mycolic acids, but contains major amounts of MK-9(H_0), MK-9(H_2), and MK-9(H_4) (points of unsaturation: III and VIII), and minor amounts of MK-9(H_6) (points of unsaturation: II, III and VIII); these components accounted for 41, 31, 25, and 7% of the total menaquinone composition, respectively. The polar lipid pattern was characterized by the presence of major amounts of phosphatidylethanolamine, hydroxylated phosphatidylethanolamine, phosphatidylinositol mannosides, ninhydrin and sugar positive components and uncharacterized glycolipids, and a trace of diphosphatidylglycerol. The diamino acid of the wall peptidoglycan is *meso*-diaminopimelic acid (Becker et al., 1965; Greiner-Mai et al., 1987).

Colony morphology. The organism produces a brown substrate mycelium, a light blue aerial mycelium, and a brown soluble pigment on glucose-yeast extract-malt and potato carrot agars (Greiner-Mai et al., 1987). On oatmeal agar, light brown colonies carry a filmy cover of farinaceous, white to yellowish-white aerial hyphae; sometimes sectors with intensified development of aerial hyphae are seen, but diffusible pigments are not formed (Meyer, 1989). A brown substrate mycelium is formed on peptone-glucose agar, but neither diffusible pigments nor aerial mycelium are produced (Meyer, 1989).

Nutrition and growth conditions. Strain DSM 43186[T] shows good to moderate growth on a range of standard media including glucose-yeast extract-malt extract and oatmeal agars, but grows poorly on Bennett's sucrose and glycerol-asparagine agars (Meyer, 1989). The organism is quite fastidious in its growth temperature and pH requirements; it does not grow below 40°C or above pH 9.0 (McCarthy and Cross, 1984).

Metabolism. Little is known about the metabolic properties of the organism. However, strain DSM 43186[T] was included in a numerical taxonomic study of monosporic actinomycetes and found to be biochemically active with an ability to degrade several complex organic compounds and use a range of sugars as sole carbon sources (McCarthy and Cross, 1984).

Antibiotic sensitivity. The organism is sensitive to a broad range of antibiotics as shown in the species description.

Maintenance procedures

The organism can be maintained on glucose-yeast extract-malt extract agar plates (ISP medium 2; Shirling and Gottlieb, 1966) and as glycerol suspensions of mycelia and spores (20%, v/v) at −20°C. Lyophilization or storage in liquid nitrogen can be used for long-term preservation.

Differentiation of the genus *Thermopolyspora* from other genera

Strain DSM 43186^T can be distinguished from members of other genera classified in the family *Streptosporangiaceae* by using a combination of chemotaxonomic and morphological properties (see Table 275 in section on family *Streptosporangiaceae*), and by 16S rRNA gene sequencing (Goodfellow et al., 2005).

Taxonomic comments

"*Thermopolyspora flexuosa*" was proposed by Krasil'nikov and Agre (1964) for a group of thermophilic actinomycetes which formed short chains of spores on short sporophores. Subsequently, the species had a tortuous taxonomic history as it was included or associated with several taxa, notably the genera *Actinomadura* (Cross and Goodfellow 1973; Lacey et al. 1978), *Micropolyspora* Krasil'nikov et al. 1968, *Nocardia* (Becker et al. 1965; Lechevalier et al. 1966a), and *Nonomuraea* Zhang et al. 1998a. It was classified in the genus *Actinomadura* in the previous edition of *Bergey's Manual of Systematic Bacteriology* (Meyer, 1989). The taxonomic position of the organism was clarified in a polyphasic taxonomic study by Goodfellow et al. (2005) who proposed that the name *Thermopolyspora flexuosa* be revived for the taxon, a proposition advanced by Greiner-Mai et al. (1987) on the basis of chemotaxonomic and morphological data. Goodfellow and his colleagues assigned the genus in the family *Streptosporangiaceae* (Goodfellow et al. 1990b) emend. Ward-Rainey et al. 1997. It is currently classified in the family *Streptosporangiaceae* (Goodfellow et al. 1990b) emend. Zhi et al. 2009.

List of species of the genus *Thermopolyspora*

1. **Thermopolyspora flexuosa** (Meyer 1989) Goodfellow, Maldonado and Quintana 2005, 1982^{VP} (*Actinomadura flexuosa* Meyer 1989, 2519)

fle.xu.o′sa. L. fem. adj. *flexuosa* full of turns or winding, tortuous, flexuous, referring to the morphology of the spore chains.

General chemotaxonomic, colonial, and morphological properties are included in the genus description. Grows well on glucose-yeast extract-malt extract, oatmeal, and peptone-glucose agars. Melanin pigments are formed from tyrosine.

Allantoin and esculin are hydrolyzed, but arbutin and urea are not. Arginine dihydrolase, catalase, citrate lyase, β-galactosidase, β-glucosidase, and oxidase are produced, but acetoin, hydrogen sulfide, lysine decarboxylase, ornithine decarboxylase, and phosphatase are not. Nitrate is reduced.

Agar, casein, DNA, elastin, gelatin, keratin, pectin, starch, testosterone, Tweens 20 and 80, tyrosine, xanthine, and xylan are degraded, but carboxymethylcellulose, chitin, guanine, hypoxanthine, and pectin are not.

L-Arabinose, fructose, galactose, glucose, maltose, mannitol, mannose, sucrose, trehalose, and xylose are used as sole carbon sources for energy and growth, but dulcitol, glycerol, inositol, inulin, lactose, melezitose, melibiose, inositol, raffinose, rhamnose, ribose, sorbitol, and sorbose (all at 1%, w/v) are not. Sodium citrate is used as a sole carbon source, but sodium oxalate (both at 0.1%, w/v) is not.

Alanine, asparagine, arginine, glutamic acid, histidine, tyrosine, and tryptophan are used as sole nitrogen sources, but ammonia salts and nitrates are not.

Grows in the presence of bile salts (0.02%, w/v), crystal violet (0.0,0002%, w/v), potassium tellurite (0.02%, w/v), sodium azide (0.01%, w/v), and thallous acetate (0.001%, w/v), but is sensitive to bile salts (0.5%, w/v), brilliant green (0.0005%, w/v), crystal violet (0.0,0005%, w/v), lysozyme (0.0025%, w/v), sodium azide (0.02%, w/v), sodium chloride (3%, w/v), tetrazolium chloride (0.002%, w/v), and thallous acetate (0.005%, w/v).

Resistant (µg per filter paper disc) to chloramphenicol (25), cephaloridine (5), cephalexin (30), cefoxitin (30), gentamicin sulfate (2), kanamycin sulfate (30), tobramycin sulfate (10), and penicillin (5U), but is sensitive to cephazolin (30), gentamicin sulfate (10), and novobiocin (50 µg/ml).

Major fatty acids (% of total) are $C_{15:0}$ iso (12.5), $C_{15:0}$ (5.7), $C_{16:0}$ iso (13.8), $C_{17:0}$ iso (18.7), $C_{17:0}$ anteiso (12.4), and $C_{17:0}$ 10 methyl-branched (6.9); minor components include $C_{15:0}$ anteiso (4.3), $C_{16:1}$ *cis* (2.8) $C_{15:0}$ iso 2-OH (1.4), $C_{16:0}$ (3.4), $C_{16:0}$ 10 methyl (2.4), $C_{16:0}$ iso 2-OH (2.5), $C_{17:0}$ (2%), $C_{17:0}$ iso 2-OH (3.0), and $C_{18:0}$ (2.5).

Source: soil collected from the Pamir mountains.

DNA G+C content (mol%): 77 (T_m).

Type strain: strain K1132, ATCC 35864, BCRC 12531, CIP 107358, DSM 43186, IMET 9552, JCM 3056, KCC A-0056, KCTC 9270, NBRC 14349, NRRL B-24348.

Sequence accession no. (16S rRNA gene): AY039253.

Additional comments: in the paper by Goodfellow et al. (2005), *Thermopolyspora* is cited as *Thermopolyspora* gen. nov., and *Thermopolyspora flexuosa* as *Thermopolyspora flexuosa* comb. nov., nom. rev. In the abstract of this paper, the strain DSM 43186 is erroneously cited as DSM 41386 [see Erratum. Int. J. Syst. Evol. Microbiol. (2005) *55*:2640]. Basonym: *Actinomadura flexuosa* (*ex* Krasil'nikov and Agre 1964) Meyer 1989, 2519; *Nonomuraea flexuosa* corrig. (Meyer 1989) Zhang et al., 1998a, 420; *Microtetraspora flexuosa* (Meyer 1989) Kroppenstedt et al., 1991, 178; "*Nocardia flexuosa*" (Krasil'nikov and Agre 1964) Becker et al., 1965, 422; "*Thermopolyspora flexuosa*" (Krasil'nikov and Agre 1964) Cross and Goodfellow 1973, 82.

Family II. **Nocardiopsaceae** (Rainey, Ward-Rainey, Kroppenstedt and Stackebrandt 1996) emend. Zhi, Li and Stackebrandt 2009, 600[VP]

Michael Goodfellow and Martha E. Trujillo

No.car.di.op.sa.ce′a.e. N.L. n. *Nocardiopsis* the type genus of the family;suff. -*aceae* ending to denote a family; N.L. fem. pl. n. *Nocardiopsaceae* the *Nocardiopsis* family.

Aerobic, Gram-stain-positive, non-acid-fast actinomycetes which form an extensively branched substrate mycelium which may bear single spores, sometimes in clusters or spore chains which terminate in pseudosporangia. **Aerial hyphae may carry single spores on dichotomously branched sporangia or differentiate into short or long chains of spores.** All spores are nonmotile. **Some strains are moderate or obligate halophiles.** Whole-cell hydrolysates contain *meso*-diaminopimelic acid as the diagnostic diamino acid. **Contains complex mixtures of saturated, unsaturated and branched-chain fatty acids, but lacks mycolic acids. Polar lipid patterns are complex. Menaquinones have nine, ten, and eleven isoprene units with varying degrees of hydrogenation.** The pattern of 16S rRNA signatures consists of nucleotides at positions 440:497 (U–U), 485 (G), 501:544 (G–C), 502:543 (A–U), 833:853 (U–G) and 1355:1367 (G–C).

Widely distributed, but common in soil, especially saline and hypersaline soils.

DNA G+C content (mol%): 64–76.

Type genus: **Nocardiopsis** (Brocq-Rousseu 1904) Meyer 1976, 487[AL].

Further descriptive information

Phylogeny. The four genera classified in the family *Nocardiopsaceae* form a distinct phyletic line in the 16S rRNA actinobacterial tree (Cai et al., 2008, 2009; Cui et al., 2001; Tang et al., 2008). In addition to *Nocardiopsis*, the type genus, the family contains the genera *Haloactinospora* Tang et al. (2008), *Streptomonospora* corrig. Cui et al. 2001 and *Thermobifida* (Zhang et al. 1998) Yang et al. 2008b. Representatives of these taxa form distinct branches in the 16S rRNA *Nocardiopsaceae* tree (Figure 389) though the position of *Nocardiopsis arabia* in the *Streptomonospora* clade is more apparent than real. This organism has chemical and morphological properties typical of *Nocardiopsis* strains (Hozzein and Goodfellow, 2008) and its position in the *Nocardiopsaceae* tree needs to be re-examined in light of the acquisition of a full 16S rRNA gene sequence. Members of all four genera share a pattern of 16S rRNA signatures (Zhi et al., 2009), as cited in the family description. The family belongs to the order *Streptosporangiales* which also encompasses the families *Streptosporangiaceae* and *Thermomonosporaceae*.

Morphology. *Nocardiopsaceae* strains typically form an extensively branched substrate mycelium, abundant aerial hyphae and nonmotile spores. However, members of the constituent genera show a range of morphological features of diagnostic value (Table 294). The aerial hyphae of *Nocardiopsis* strains, for instance, are either long and moderately branched, straight and flexuous or irregularly zig-zagged, completely fragmenting into oval to elongated, rod-shaped smooth-surfaced spores (Chen et al., 2008; Hozzein and Goodfellow, 2008; Meyer, 1976, 1989). Short straight to flexuous chains of oval, cylindrical or rod-shaped spores are formed on the aerial mycelium of *Streptomonospora* strains (Cai et al., 2008, 2009; Cui et al., 2001; Li et al., 2003b) and long chains of cylindrical spores with smooth surfaces on the aerial mycelium of *Haloactinospora alba* YIM 90648^T, the sole member of this genus (Tang et al., 2008). In contrast, the aerial mycelium of *Thermobifida* strains carry oval to round, single spores on dichotomously branched sporophores which give the appearance of spore clusters; the latter may also be seen occasionally on the substrate mycelium (Yang et al., 2008b; Zhang et al., 1998). Characteristic chains of wrinkled spores terminating in pseudosporangia are borne on the substrate mycelium of the *Haloactinospora alba* strain (Tang et al., 2008) while single, oval or round spores with wrinkled surfaces are formed on either sporophores or dichotomously branching sporophores on the substrate mycelium of members of the genus *Streptomonospora* (Cai et al., 2008, 2009; Cui et al., 2001; Li et al., 2003b).

Chemotaxonomy. Members of the family contain *meso*-diaminopimelic acid as the wall diamino acid and hence have a wall chemotype III *sensu* Lechevalier and Lechevalier (1970b). *Nocardiopsis* and *Thermobifida* strains lack diagnostic sugars (Kroppenstedt and Evtushenko, 2006) whereas *Streptomonospora* strains contain galactose or arabinose and galactose as a characteristic wall sugar (Cai et al., 2008, 2009; Cui et al., 2001) and *Haloactinospora* galactose and ribose (Tang et al., 2008). Members of the family have complex polar lipid patterns with *Streptomonospora* and *Thermobifida* exhibiting a type II and *Haloactinospora* and *Nocardiopsis* a type III profile after Lechevalier et al. (1977, 1981). All four genera are characterized by complex menaquinone (Table 294) and fatty acid profiles; the latter typically contain large proportions of 14-methylpentadecanoic ($C_{16:0}$ iso) and 14-methylhexadecanoic acid ($C_{17:0}$ anteiso) (Kroppenstedt and Evtushenko, 2006; Tang et al., 2008). The menaquinone composition of some *Streptomonospora* strains is influenced by the growth media (Li et al., 2003b); medium-dependent shifts in menaquinone profiles have been reported for *Micrococcus luteus* (Hiraishi and Komagata, 1989) and age-dependent ones in *Streptomyces cyaneus* (Saddler et al., 1986). Teichoic acids are valuable taxonomic markers for the subgeneric classification of *Nocardiopsis* species (Kroppenstedt and Evtushenko, 2006; Naumova et al., 2001). The cell walls of *Thermobifida fusca* also contain teichoic acids (Potekhina et al., 2003) and a polyglycerophosphate lipoteichoic acid (Rahman et al., 2009).

Differentiation of the genera of the family *Nocardiopsaceae*

The genera classified in the family *Nocardiopsaceae* can be distinguished by using a combination of chemotaxonomic, morphological and physiological criteria (Table 294), by 16S rRNA gene signature nucleotides (Tang et al., 2008) and by comparisons of 16S rRNA gene sequenced data (Figure 389). Standard chemotaxonomic procedures can be used for the detection of diagnostic amino acids and sugars in whole-cell hydrolysates (Hasegawa et al., 1983; Staneck and Roberts, 1974), cellular fatty acids (Kroppenstedt, 1985; Sasser, 1990), and polar lipid patterns (Minnikin et al., 1984). Detailed

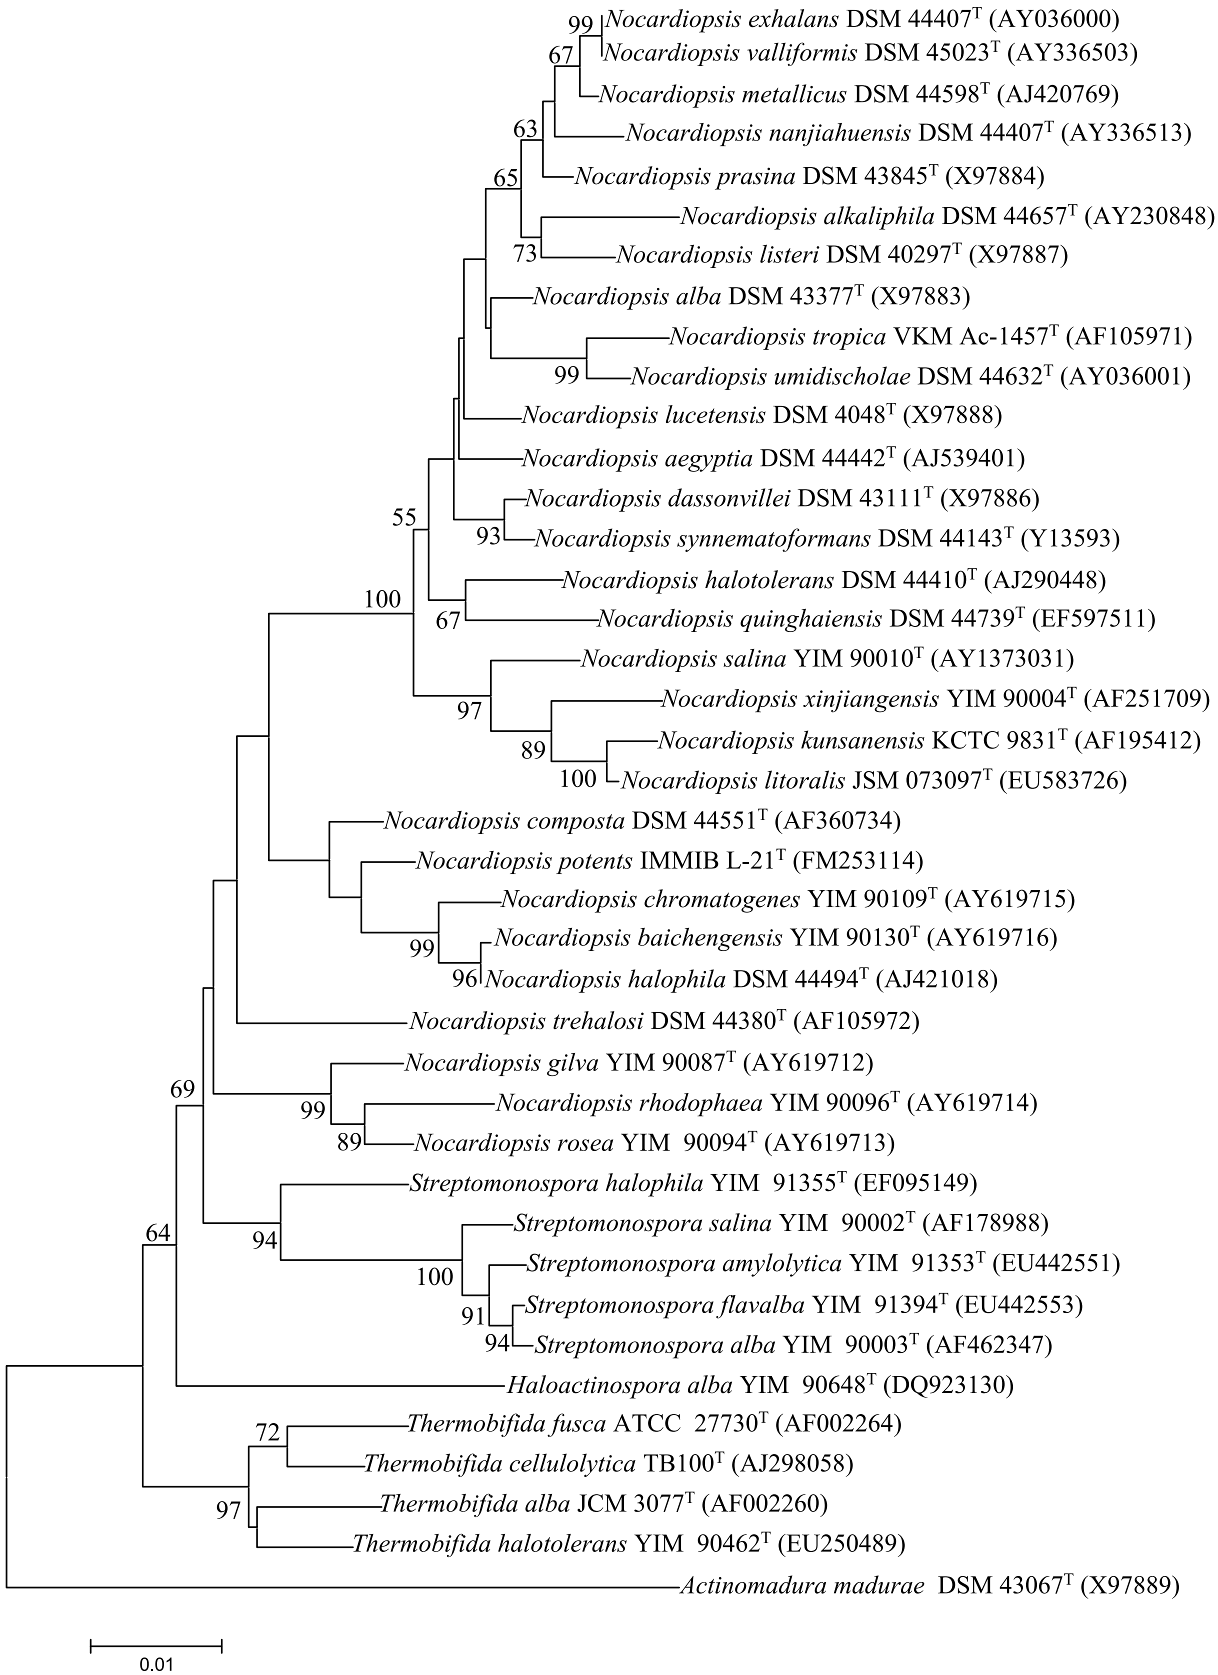

FIGURE 389. Neighbor-joining tree based on 16S rRNA gene sequences showing relationships between taxa classified in the family *Nocardiopsaceae*. Evolutionary distances were calculated using the Kimura two-parameter method of Kimura (1980). Numbers at the nodes are bootstrap values based on 1000 resampled datasets, only values above 50% are given. Bar, 1 nucleotide difference per 100 nucleotides.

TABLE 294. Properties that distinguish between the genera classified in the family *Nocardiopsaceae*[a]

[a]Data taken from Cui et al. (2001), Cai et al. (2008, 2009), Kroppenstedt and Evtushenko (2006), Li et al. (2003b), Tang et al. (2008) and Zhang et al., (1998).

[b]Fatty acid types according to Kroppenstedt (1985); nd, not determined.

[c]Abbreviations for phospholipids: DPG, diphosphatidylglycerol; PC, phosphatidylcholine; PE, phosphatidylethanolamine; PG, phosphatidylglycerol; PI, phosphatidylinositol; PIM, phosphatidylinositol mannoside(s); PME, phosphatidylmethylmonoethanolamine; PS, phosphatidylserine; (), variable distribution.

analytical procedures are available for establishing menaquinone profiles (Kroppenstedt, 1982, 1985) (Collins, 1994), including the integrated method introduced for the analysis of bacterial isoprenoid quinones and polar lipids (Minnikin et al., 1984). Genus-specific primers are available for the PCR identification of novel *Streptomonospora* strains (Cai et al., 2009; Zhi et al., 2006).

Genus I. **Nocardiopsis** Meyer 1976, 487[AL]

Wael N. Hozzein and Martha E. Trujillo

No.car.di.op′sis. N.L. fem. n. *Nocardia* a genus of the order *Actinomycetales*; Gr. fem. n. *opsis* appearance; N.L. fem. n. *Nocardiopsis* that which has the appearance of *Nocardia*.

Gram-stain-positive, aerobic, chemo-organotrophic, **non-acid-fast**, nonmotile filamentous actinomycetes. Substrate mycelium is well developed and hyphae are long and densely branched. **Fragmentation into coccoid and bacillary elements may occur.** Aerial mycelium is well developed and sparse-to-abundant; **aerial hyphae are long**, branched, **straight to flexuous, or irregularly zig-zagged**, **completely fragmenting into spores of various lengths. Spore surface is smooth. Wall peptidoglycan** contains ***meso*-diaminopimelic acid** and the muramic acid of the peptidoglycan is acetylated. No diagnostic sugars are found in whole-organism hydrolysates. **Mycolic acids are absent.** Major phospholipids are **phosphatidylcholine**, phosphatidylmethylethanolamine, phosphatidylglycerol, and phosphatidylinositol, with small amounts of diphosphatidylglycerol. Menaquinones are predominantly variably hydrogenated with ten isoprene units **(MK-10)**, with minor amounts of the **MK-9** and/or **MK-11** series. The main fatty acids are branched and **10-methyl-branched fatty acids, 14-methyl-heptadecanoic acid, and 14-methyl-hexadecanoic acid.** Growth temperature range is 10–45°C. Widely distributed in saline and alkaline soils, and found in compost, vegetable matter, indoor environments, and clinical material of animal and human origin.

DNA G+C content (mol%): 64–69.

Type species: **Nocardiopsis dassonvillei** (Brocq-Rousseau 1904) Meyer 1976, 487[AL].

Further descriptive information

Phylogeny. The genus *Nocardiopsis* is the type genus of the family *Nocardiopsaceae* (Rainey et al., 1996) emend. Zhang et al. (1998), which also includes the genera *Haloactinospora* Tang et al. (2008), *Streptomonospora* (Cui et al., 2001) emend. Li et al. (2003b), and *Thermobifida* (Zhang et al., 1998) emend. Yang et al. (2008b). Phylogenetically, these genera form a distinct and coherent phyletic line in the 16S rRNA gene tree (Cui et al., 2001; Kroppenstedt and Evtushenko, 2006; Tang et al., 2008; Zhang et al., 1998) and can be clearly distinguished from the other two families comprising the suborder *Streptosporangineae* Ward-Rainey et al. 1997, elevated to order *Streptosporangiales* in the present volume, namely the families *Streptosporangiaceae* and *Thermomonosporaceae* (Goodfellow and Quintana, 2006; Gyobu, 2001; Kudo, 2001). The pattern of 16S rRNA signatures consists of nucleotides at positions 440:497 (C–G), 501:544 (C–G), 502:543 (G–C), 831:855 (G–G) 843 (U), 844 (A), and 1355:1367 (A–U) (Zhi et al., 2009).

The genus *Nocardiopsis*, which currently contains 30 species, does not appear to be monophyletic according to 16S rRNA

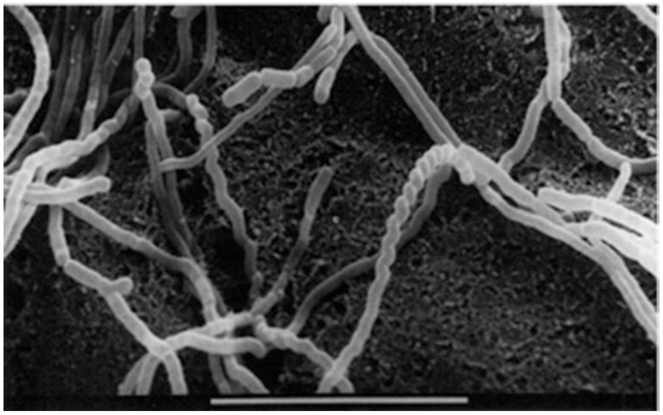

FIGURE 390. Scanning electron micrograph of strain *Nocardiopsis lucentensis* A5-1T^{T}, showing zig-zag hyphae and spore chain with a smooth surface. The culture was grown on ISP medium 4 supplemented with 10% NaCl for 14 d at 35°C. Bar = 1 μm. (Reproduced with permission from Yassin et al., 1993. Int. J. Syst. Bacteriol. *43*: 266–271.)

gene sequence phylogeny (see Figure 389). *Nocardiopsis* species are divided in four phyletic groups, the largest, with 20 species, includes the type species *Nocardiopsis dassonvillei*. On the other hand, a single member cluster is formed by *Nocardiopsis trehalosi*.

Cell morphology. Members of the genus *Nocardiopsis* characteristically form a well-developed and branched substrate mycelium which may fragment into coccoid and bacillary elements. Aerial mycelium production varies from sparse to abundant. The aerial hyphae formed by some strains may not be visible to the unaided eye, requiring careful observation under a microscope. Other cultures are thickly covered with a powdery to velvety aerial mycelium simulating cultures of *Streptomyces griseus* (cf. Gordon and Horan, 1968) because of the yellowish-gray color. Aerial hyphae are long, moderately branched, straight, or flexuous. Initiation of sporulation is often characterized by twisted hyphae, which by examination at higher magnification, reveal a zig-zag arrangement of the developing spores (Figure 390). The elongated spores are smooth and can divide subsequently into smaller spores of irregular size by cross-wall formation. Spores are enclosed within a fibrillar sheath and have thickened polar walls (Williams et al., 1974). *Nocardiopsis synnemataformans* is the only species known to form synnemata from spiral aerial hyphae that wrap together to form long ropes that subsequently fragment into small rod-shaped elements (Figure 391) (Yassin et al., 1997). *Nocardiopsis* strains do not produce sporangia, sclerotia, or motile elements.

The morphology of *Nocardiopsis* resembles that of other arthrospore-forming actinomycetes. However, members of the genus can be presumptively recognized based on various specific macroscopic and microscopic features. Although many *Nocardiopsis* strains resemble some *Streptomyces* strains macroscopically (Gordon and Horan, 1968; Shirling and Gottlieb, 1972), the two genera can be distinguished by direct microscopic comparison of cultures based on their type of life cycle and spore formation. In *Streptomyces*, spores are delimited basipetally almost simultaneously, whereas in *Nocardiopsis*, the cross

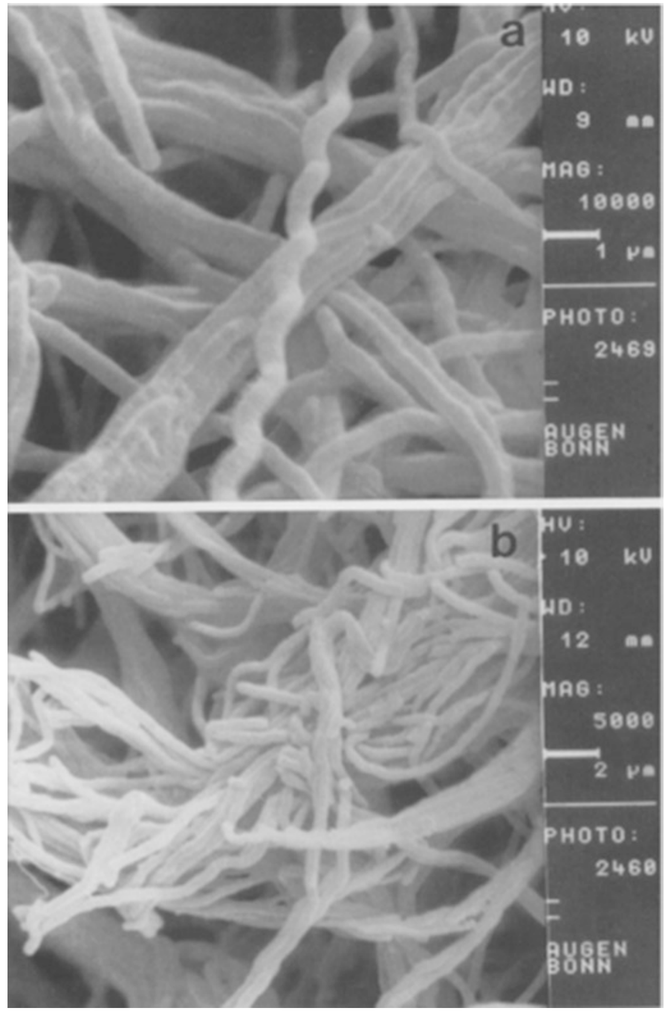

FIGURE 391. Scanning electron micrographs of *Nocardiopsis synnemataformans* strain IMMIB D-1215^{T}, showing spiral hyphae wrapped together to form synnemata (a), which fragment into small rod-shaped elements (b). (Reproduced with permission from Yassin et al., 1997. Int. J. Syst. Bacteriol. *47*: 983–988.)

walls are formed in a relatively uncoordinated manner resulting in spores of various lengths. *Nocardiopsis* species can also differentiated by their nocardioform life cycle.

Cell-wall composition. Members of the genus *Nocardiopsis* have cell-wall chemotype III, which corresponds to peptidoglycan type A1 (Schleifer and Kandler, 1972), i.e. strains contain 2,6-*meso*-diaminopimelic acid (*meso*-DAP), alanine, and glutamic acid in their peptidoglycan. The muramic acid of the peptidoglycan is acetylated (Kroppenstedt, 1987). In whole-cell hydrolyzates, glucose and galactose are detected, but no diagnostic sugars have been found in any of the species analyzed. Cell-wall teichoic acids are present and composed of glycerol and other constituents, like ribitol, glucosamine, galactosamine, succinic, and propionic acids (Naumova et al., 2001). Teichoic acid polymers are considered a valuable chemotaxonomic marker for the intrageneric taxa of *Nocardiopsis* (Kroppenstedt and Evtushenko, 2006; Streshinskaya et al., 1989, 1996, 1998; Tul'skaya et al., 1993, 2000).

Polar lipids. Members of the genus *Nocardiopsis* show a characteristic phospholipid type III profile (Lechevalier et al., 1977) with phosphatidylcholine (PC) as the characteristic polar lipid, plus phosphatidylmethylethanolamine (PME), phosphatidylglycerol (PG), phosphatidylinositol (PI), and small amounts of diphosphatidylglycerol (DPG). Additionally, two spots of glycolipids, identified as monomannosyl diglyceride and monoacetylated glucose, right below the PME spot and two to four unidentified phospholipids above the DPG spot can be detected on two-dimensional thin-layer chromatography plates as additional lipid markers (Grund, 1987; Grund and Kroppenstedt, 1990; Kroppenstedt and Evtushenko, 2006; Minnikin et al., 1977, 1984; Mordarska et al., 1983, 1998).

Menaquinone composition. Members of the genus *Nocardiopsis* show complex menaquinone profiles containing predominant amounts of MK-10(H_0) to MK-10(H_8) and small amounts of the MK-9 and/or MK-11 series (Fischer et al., 1983; Grund and Kroppenstedt, 1990; Minnikin et al., 1978).

Fatty acid profile. *Nocardiopsis* strains are characterized by terminally branched and 10-methyl-branched fatty acids (with chain lengths of 14–18 carbons), but hydroxy fatty acids have never been detected (Grund and Kroppenstedt, 1990; Kroppenstedt and Evtushenko, 2006). Among the terminally branched fatty acids, 14-methyl-heptadecanoic acid ($C_{16:0}$ iso) and 14-methyl-hexadecanoic acid ($C_{17:0}$ anteiso) are the main components. Smaller amounts of the 10-methyl branched tuberculostearic acid, i.e. 10-methyl-octadecanoic acid ($C_{18:0}$10-methyl), and its precursor the unsaturated *cis*9,10 octadecenoic acid ($C_{18:1}$ *cis*) are also found (Grund and Kroppenstedt, 1990). This fatty acid profile belongs to fatty acid type 3d according to Kroppenstedt (1985).

Cultural characteristics. *Nocardiopsis* species tend to grow well on both complex and defined media. Most strains show good to abundant growth on modified Bennett's (Jones, 1949), Czapek–Dox, nutrient (Waksman, 1961b), and glucose-yeast extract-malt extract (Athalye et al., 1981) agars, and on formulations of the International *Streptomyces* Project (ISP media; Shirling and Gottlieb, 1966). Several *Nocardiopsis* species may require NaCl for optimal growth. The halotolerant or moderately halophilic species, *Nocardiopsis halophila*, *Nocardiopsis kunsanensis*, *Nocardiopsis salina*, and *Nocardiopsis xinjiangensis* grow optimally on most ISP media in the presence of 10–15% (w/v) NaCl (Al-Tai and Ruan, 1994; Chun et al., 2000; Li et al., 2003a, 2004).

Nutrition and growth conditions. *Nocardiopsis* strains are strictly aerobic and chemo-organotrophic with an oxidative metabolism. Most species grow well at 10–40°C with an optimum growth temperature of 28–30°C; in addition, several *Nocardiopsis* species are considered thermotolerant organisms and may grow at 45–50°C, with an optimal growth temperature of 37°C, namely, *Nocardiopsis baichengensis*, *Nocardiopsis chromatogenes*, *Nocardiopsis composta*, *Nocardiopsis kunsanensis*, *Nocardiopsis rhodophaea*, and *Nocardiopsis rosea* (Chun et al., 2000; Kämpfer et al., 2002; Li et al., 2006). One thermophilic *Nocardiopsis* isolate, KMD/8, which is able to grow at 65°C with an optimal growth temperature of 50°C, was reported by Kempf (1995).

Nocardiopsis strains can tolerate NaCl concentrations up to 20% (w/v). Halotolerant species include *Nocardiopsis baichengensis*, *Nocardiopsis chromatogenes*, *Nocardiopsis composta*, *Nocardiopsis gilva*, *Nocardiopsis halotolerans*, *Nocardiopsis rhodophaea*, and *Nocardiopsis rosea*, which can grow in media supplemented with 15–18% (w/v) NaCl (Al-Zarban et al., 2002; Kämpfer et al., 2002; Li et al., 2006). Only *Nocardiopsis halophila*, *Nocardiopsis kunsanensis*, *Nocardiopsis xinjiangensis*, and *Nocardiopsis salina* (Al-Tai and Ruan, 1994; Chun et al., 2000; Li et al., 2003a, 2004) are considered as true halophilic species as NaCl (at least 3%, w/v) is necessary for growth, with an optimal concentration of 10–15% (w/v).

Most *Nocardiopsis* strains are characterized by their alkaliphilic behavior as they prefer mild alkaline conditions and some can even grow at pH 13. Alkaliphilic species include *Nocardiopsis alkaliphila*, *Nocardiopsis ganjiahuensis*, *Nocardiopsis kunsanensis*, *Nocardiopsis litoralis*, *Nocardiopsis metallicus*, *Nocardiopsis prasina*, and *Nocardiopsis valliformis* (Chen et al., 2009; Hozzein et al., 2004; Miyashita et al., 1984; Schippers et al., 2002; Yang et al., 2008c; Zhang et al., 2008).

Nocardiopsis strains can utilize a wide range of carbohydrates as carbon sources. They also hydrolyze and degrade diverse compounds. A list of these substrates is given in Table 295.

Pigments. Most *Nocardiopsis* strains do not produce diffusible pigments. However, Gerber (1966) reported that various *Nocardiopsis dassonvillei* strains produced purple colored crystals which were identified as iodinin crystals. Gordon and Horan (1968) also reported the production of yellowish, greenish-yellow, or brown diffusible pigments by strains of the same species. *Nocardiopsis tropica* produces yellow-orange soluble pigments on oatmeal agar or glycerol-yeast extract agar (Evtushenko et al., 2000), whereas *Nocardiopsis chromatogenes* was found to produce a diffusible yellowish-pink pigment on Czapek and ISP 5 agar (Li et al., 2006).

Genetics. Similarity values between the 16S rRNA gene sequences of strains of *Nocardiopsis* species with validly published names range from 93.6 to 99.9%; 41.3% of the similarity values are ≥97%. Although many type strains in the genus share a 16S rRNA gene sequence similarity of 99%, DNA–DNA reassociation values are well below 70%. A value of 55.9% between *Nocardiopsis halophila* and *Nocardiopsis baichengensis* has been reported (Li et al., 2006) and the DNA–DNA values of *Nocardiopsis metallicus* with *Nocardiopsis exhalans* and *Nocardiopsis prasina* are 18.2% and 44.1%, respectively (Schippers et al., 2002).

The *gyrB*, *sod*, and *rpoB* partial gene sequences of strains of 24 *Nocardiopsis* species with validly published names have been determined; the mean similarities of the *gyrB*, *sod* and *rpoB* genes of *Nocardiopsis* species were 87.7%, 87.3%, and 94.1% (that of the 16S rRNA gene of *Nocardiopsis* species studied was 96.6%). The topology of the *gyrB* gene tree showed a high consistency with that of the 16S rRNA gene tree suggesting that the *gyrB* gene could be used as a taxonomic phylogenetic marker with a higher degree of discrimination between the species studied (Yang et al., 2007a, 2008a).

Genes encoding industrially important enzymes such as β-1,3-glucanase and chitinases ChiA and ChiB, from two alkaliphic *Nocardiopsis* strains (F96 and *Nocardiopsis prasina* OPC-131, respectively), have been cloned, sequenced, and expressed in *Escherichia coli* (Masuda et al., 2003; Tsujibo et al., 2003). Sequencing of the whole genome of *Nocardiopsis dassonvillei* DSM 43111[T] is underway (Project ID: 19709 at DOE Joint Genome Institute).

Phages. Four *Nocardiopsis* phages were reported by Prauser (1981); however, information about their taxon specificity is still lacking. Clearing effects caused by soil-isolated polyvalent *Streptomyces* phages on *Nocardiopsis dassonvillei* raised speculations about the relationship of these two taxa (Prauser, 1984). However, these two genera can be clearly differentiated and this may only be due to the phage's specificity.

Pathogenicity. The isolation of *Nocardiopsis* strains from human or animal clinical material is well documented (Goodfellow, 1998; Schaal and Beaman, 1984). Like most other actinomycete pathogens, *Nocardiopsis* species are opportunistic rather than invasive pathogens. Liegard and Landrieu (1911) reported the isolation of a strain matching the description of Brocq-Rousseau (1904) from a case of ocular conjunctivitis where they gave it the name *Nocardia dassonvillei*, which later became *Nocardiopsis dassonvillei* (Meyer, 1976). Gordon and Horan (1968) reported that 15 of the 26 *Nocardiopsis* strains in their collection originated from clinical isolates. They speculated that similar cultures from other clinical sources might usually be discarded in laboratories because of their macroscopic resemblance to the genus *Streptomyces*.

The implication of *Nocardiopsis dassonvillei* in skin infections has also been reported (Philip and Roberts, 1984; Singh et al., 1991). The first case of mycetoma caused by *Nocardiopsis dassonvillei* was published by Sindhuphak et al. (1985), who repeatedly isolated *Nocardiopsis dassonvillei* strains from nodules and draining sinuses from the leg of a 39-year-old man. Ajello et al. (1987) confirmed the presence of *Nocardiopsis dassonvillei* in actinomycetoma cases. Furthermore, *Nocardiopsis dassonvillei* is involved in broncho-pulmonary infections (Bernatchez and Lebreux, 1991; Gugnani et al., 1998; Mordarska et al., 1998) and has also been recovered from blood samples (Beau et al., 1999). Although the pathogenicity of *Nocardiopsis synnemataformans* isolated from the sputum of a kidney transplant patient could not be verified, this species is regarded as a potential pathogen.

Antibiotic sensitivity. Very little is known about antibiotic sensitivity of clinical *Nocardiopsis* strains and only a few studies have been carried out. Philip and Roberts (1984) reported that a cutaneous infection caused by *Nocardiopsis dassonvillei* in an elderly man responded to oral treatment with trimethoprim-sulfamethoxazole. Yassin et al. (1997) examined *Nocardiopsis synnemataformans* for its sensitivity by using the agar dilution technique. They reported the following minimum inhibitory concentrations (μg/ml) for: mezlocillin (2.0); amoxycillin plus clavulanic acid (2.0); imipenem (2.0); erythromycin (8.0); clindamycin (>128); tetracycline (≤0.2); vancomycin (≤0.2); gentamicin (≤0.2); tobramycin (≤0.2); amikacin (≤0.2); ciprofloxacin (2.0); and ofloxacin (8.0). In an earlier study, Yassin et al. (1993) also reported that *Nocardiopsis lucentensis* is resistant to lincomycin (128 μg/ml), penicillin G (128 μg/ml), gentamicin (64 μg/ml), streptomycin (64 μg/ml), and neomycin (4 μg/ml), but not to rifampin (128 μg/ml). Similarly, Al-Tai and Ruan (1994) used the paper disk-diffusion method to assess the susceptibility of *Nocardiopsis halophila* and found that it was resistant to amoxycillin, clindamycin, bacitracin, cephalexin, and oxacillin, but susceptible to carbenicillin, chloramphenicol, erythromycin, and novobiocin.

Secondary metabolites. *Nocardiopsis* strains are also known for their potential to produce bioactive metabolites. A disaccharide antibiotic (3-trehalosamine) active against Gram-stain-positive bacteria was reported to be synthesized by *Nocardiopsis trehalosi* (Dolak et al., 1980, 1981). Phenazine antibiotics were obtained from the alkaliphilic *Nocardiopsis* strain OPC-15, which produced different phenazine antibiotics under different culture conditions (Tsujibo et al., 1988). In addition, 1,6-dihydroxyphenazine was obtained from the mycelium after incubation for 6–8 d at 27°C, whereas 1,6-dihydroxyphenazine-5,10-dioxide, known as iodinin, was isolated after incubation for 6 d at 27°C followed by further incubation for 2 d at 4°C. The production of a new indole alkaloid, pendolmycin, by *Nocardiopsis* strain SA 1715, isolated from soil collected in a river near Shanghai, was reported by Yamashita et al. (1988). Members of the genus also produce apoptolidins, new apoptosis inducers in transformed cells (Kim et al., 1997; Wender and Longcore, 2009; Wender et al., 2005).

In the last decade, some bioactive compounds have been discovered from *Nocardiopsis* strains isolated from marine samples. Kahakamides A and B, two new neosidomycin antibiotics (a group of rare indole-*N*-glycosides) were isolated from a *Nocardiopsis dassonvillei* strain (Schumacher et al., 2001). Also, a novel cyclic tetrapeptide was obtained from the culture broth of a marine *Nocardiopsis* isolate (Shin et al., 2003).

A marine-derived actinomycete, *Nocardiopsis* sp. (CMB-M0232), obtained from a sediment sample collected at a depth of 55 m off the coast of Brisbane, Australia, yielded two new FKBP12-binding macrolide polyketides named nocardiopsins A and B (Raju et al., 2010).

As expected, alkalitolerant/alkaliphilic *Nocardiopsis* strains can synthesize many different alkaline enzymes. These compounds have been reported from different *Nocardiopsis* strains (Moreira et al., 2002, 2003). In addition, three chitinases from the alkaliphilic *Nocardiopsis prasina* OPC-131 (Tsujibo et al., 2003), a keratinolytic protease from the alkaliphilic *Nocardiopsis* sp. strain TOA-1 (Mitsuiki et al., 2004), an alkaline protease from *Nocardiopsis* sp. (Monteiro et al., 2005), an endo-1,3-β-glucanase from the alkaliphilic *Nocardiopsis* sp. strain F96 (Fibriansah et al., 2006), and an endo-β-1,4-D-glucanase from the alkalitolerant *Nocardiopsis* sp. SES28 (Walker et al., 2006) have also been isolated. Moreover, a thermostable α-amylase from *Nocardiopsis* sp. was reported by Stamford et al. (2001) and an acid-resistant protease enzyme produced by a strain of *Nocardiopsis alba* was studied by Kelch et al. (2007).

Degradation of organic polymers and transformation of organic compounds have also been reported as applications of some *Nocardiopsis* species. Ghanem et al. (2005) published the first report on the degradation of polyesters, poly(3-hydroxybutyrate) and its copolymers with poly(3-hydroxyvalerate) [poly(3-hydroxybutyrate-co-10–20%-hydroxyvalerate)], by the marine species *Nocardiopsis aegyptia*. Moreover, in a review on transformation of steroids by actinobacteria, Donova (2007) reported that representatives of *Nocardiopsis* are capable of hydroxylating dehydroepiandrosterone.

Ecology. The natural habitat of *Nocardiopsis* strains appears to be the soil where they are frequently isolated together with other actinobacteria (Dolak et al., 1980, 1981; Mikami et al., 1982; Mishra et al., 1987; Wang et al., 1999; Xu et al., 1998). Zitouni et al. (2005) isolated 86 strains from soil samples collected from the Algerian Sahara (desert) and found that 54 isolates belonged to the genus *Nocardiopsis*, whereas Hozzein and colleagues isolated novel *Nocardiopsis* species from desert and sand dune soil samples from Egypt (Hozzein and Goodfellow,

2008; Hozzein et al., 2004). Many *Nocardiopsis* strains have also been found in soils with high salt concentrations (Al-Tai and Ruan, 1994; Al-Zarban et al., 2002; Chen et al., 2008; Chun et al., 2000; Li et al., 2004, 2006; Yassin et al., 1993). Alkaliphilic soils are also a good source for the recovery of *Nocardiopsis* strains. Jiang and Xu (1998) reported that 9 of 49 actinomycetes isolated from alkaline soils were *Nocardiopsis* strains, all grew at pH 12, but six isolates were obligate alkaliphilic strains growing at pH 8–12 but not at pH 7.

In addition, *Nocardiopsis* species have also been reported from other sources including: cotton waste and hay (Lacey, 1977); an Antarctic glacier (Abyzov et al., 1983); deep-sea sediments (Zhang and Zeng, 2008); ovaries of puffer fish (Wu et al., 2005); indoor environments (Peltola et al., 2001); a composting facility (Kämpfer et al., 2002); and a cattle barn (Andersson et al., 1998).

Distribution and abundance of members of the genus *Nocardiopsis* in marine habitats was reported recently (Sabry et al., 2004; Schumacher et al., 2001; Shin et al., 2003). In studies on the diversity of culturable actinobacteria isolated from the marine sponges, *Hymeniacidon perleve*, *Haliclona* sp., and *Iotrochota* sp., *Nocardiopsis* strains were frequently found and it was the second dominant genus after *Streptomyces* in most cases (Jiang et al., 2007, 2008; Zhang et al., 2006).

The presence and isolation of *Nocardiopsis* strains from clinical material including actinomycetomas is well documented (Ajello et al., 1987; Beau et al., 1999; Gugnani et al., 1998; Liegard and Landrieu, 1911; Mordarska et al., 1998; Sindhuphak et al., 1985; Singh et al., 1991; Yassin et al., 1997).

Enrichment and isolation procedures

No specific enrichment or isolation procedures have been recommended for *Nocardiopsis* (Meyer, 1989) and isolation protocols described for streptomycetes are commonly used (Korn-Wendisch and Kutzner, 1992). Most strains grow readily on a variety of media, especially those recommended by the International Streptomycetes Project (ISP); those that have proved to be most effective include yeast extract-malt extract (ISP medium 2), oatmeal (ISP medium 3), glycerol-asparagine (ISP medium 5) (Shirling and Gottlieb, 1966) and glucose-yeast extract-peptone (Naumova et al., 1980) agars and most strains may be recovered from agar plates after incubation at 28–30°C for 7–14 d. Horikoshi (1971) devised a special method for the isolation of alkaliphic *Nocardiopsis* strains: a small amount of soil is suspended in 1 ml sterilized water, 100 µl aliquots of the suspension are spread on dry agar plates, and the plates are incubated for 7–14 d at 27°C. In general, for isolation of alkaliphilic *Nocardiopsis* strains, the pH has to be adjusted to 10 or above with sterile sodium carbonate or sodium hydroxide after autoclaving the isolation medium and the plates should be incubated for 7–14 d at 28°C (Hozzein et al., 2004; Miyashita et al., 1984; Yang et al., 2008c; Zhang et al., 2008).

Various media supplemented with 5–20% (w/v) NaCl have been used to isolate halophilic *Nocardiopsis* strains (Al-Tai and Ruan, 1994; Al-Zarban et al., 2002; Chun et al., 2000; Li et al., 2006; Li et al., 2004; Yassin et al., 1993).

Maintenance procedures

Nocardiopsis strains can be maintained on appropriate media agar slants at 4°C and transferred every 4 months for short-term preservation. To prevent the agar from drying, the tubes should be tightly sealed with silicone stoppers. Medium-term preservation for up to 4 years can be achieved by preparing spore suspensions and/or homogenized mycelia in glycerol (45%, v/v) and keeping them at −25°C (Wellington and Williams, 1978). Storage in liquid nitrogen and lyophilization can be used for long-term storage. For lyophilization, spores and mycelia are suspended in a suitable suspension agent such as skimmed milk (10%, w/v). Storage in liquid nitrogen can be achieved by inoculation of the micro-organisms into small vials containing an appropriate medium which are then incubated until satisfactory growth is visible; the tubes are then tightly sealed and placed in a liquid nitrogen container. Alternatively, a simple, reliable and time-saving method is liquid nitrogen cryopreservation of living cells in small PVC tubes at −196°C (Hoffman, 1989a, 1989b).

Taxonomic comments

The strain that gave its name to the type species of the genus *Nocardiopsis* was originally isolated from mildewed grain and named *Streptothrix dassonvillei* by Brocq-Rosseau (1904), but unfortunately this strain was lost. In 1911, Liegard and Landrieu isolated a micro-organism from a case of ocular conjunctivitis that they found to be similar to the lost strain; however, these authors proposed to include the novel isolate in the genus *Nocardia* as *Nocardia dassonvillei*. Knowledge concerning *Nocardia dassonvillei* was scarce until Gordon and Horan (1968) discovered that the macroscopic appearance and a number of the physiological characters of *Nocardia dassonvillei* were similar to those of *Streptomyces griseus*. Subsequently, Lechevalier and Lechevalier (1970a) transferred *Nocardia dassonvillei* to the genus *Actinomadura* as *Actinomadura dassonvillei*, primarily on the basis of chemical properties.

The genus *Nocardiopsis* was subsequently proposed to accommodate *Actinomadura dassonvillei* as strains of this micro-organism lacked the characteristic whole-organism hydrolysate sugar madurose and formed spores in a distinctive zig-zag formation on aerial hyphae (Meyer, 1976). Additional chemical (Athalye et al., 1984; Collins et al., 1977; Fischer et al., 1983; Lechevalier et al., 1977a; Minnikin et al., 1977; Yamada et al., 1977) and numerical phenetic data (Alderson and Goodfellow, 1979; Athalye et al., 1985; Goodfellow et al., 1979; Goodfellow and Pirouz, 1982) strongly supported the recognition of the genus *Nocardiopsis* with *Nocardiopsis dassonvillei* as the type species.

16S rRNA gene sequence data confirmed the separation between *Nocardiopsis dassonvillei* and *Actinomadura madurae* and showed *Nocardiopsis* to be most closely related to the genera *Microtetraspora* and *Streptomyces* (Goodfellow et al., 1988; Kroppenstedt et al., 1990), whereas the nocardioform soil isolate *Saccharothrix australiensis* (Labeda et al., 1984), which resembles *Nocardiopsis dassonvillei* morphologically and in some chemotaxonomic characters, was found to be closely related to members of the family *Pseudonocardiaceae* (Bowen et al., 1989).

Six of the eight *Nocardiopsis* species with validly published names were subsequently considered to be misclassified (Grund and Kroppenstedt, 1989, 1990). *Nocardiopsis coeruleofusca*, *Nocardiopsis flava*, *Nocardiopsis longispora*, *Nocardiopsis mutabilis*, and *Nocardiopsis syringae* were classified in the genus *Saccharothrix* (Grund and Kroppenstedt, 1989; Labeda and Lechevalier, 1989) as *Saccharothrix coeruleofusca*, *Saccharothrix*

flava, *Saccharothrix longispora*, *Saccharothrix mutabilis*, and *Saccharothrix syringae*, respectively, and *Nocardiopsis africana*, was assigned to the genus *Microtetraspora* as *Microtetraspora africana* (Goodfellow et al., 1988; Kroppenstedt et al., 1990; Poschner et al., 1985). The remaining two species, *Nocardiopsis alba* and *Nocardiopsis dassonvillei*, stayed in the genus *Nocardiopsis* (Fischer et al., 1983; Grund, 1987). *Saccharothrix flava* was later transferred to the genus *Lechevalieria* (Labeda et al., 2001) and *Microtetraspora africana*, together with most other species of the genus *Microtetraspora*, to *Nonomuraea* (Zhang et al., 1998).

Based on phenetic data, Meyer concluded that the remaining single species, *Nocardiopsis antarctica*, was a synonym of *Nocardiopsis dassonvillei* (Meyer, 1989); these results were confirmed by 16S rRNA gene sequences and DNA–DNA hybridization results and *Nocardiopsis antarctica* was transferred to *Nocardiopsis dassonvillei* (Yassin et al., 1997).

Molecular and phenotypic data showed that all tested strains of *Nocardiopsis dassonvillei* should be divided into two species (Fischer et al., 1983; Grund, 1987). On the basis of these results and those of some additional studies, a novel species, *Nocardiopsis alba*, was created (Grund and Kroppenstedt, 1990). This study showed in addition that *Nocardiopsis dassonvillei* subsp. *prasina* was actually more closely related to *Nocardiopsis alba* than to *Nocardiopsis dassonvillei*. This subspecies was therefore transferred to *Nocardiopsis alba* with the revision of its name to *Nocardiopsis alba* subsp. *prasina*. Yassin et al. (1997) subsequently described *Nocardiopsis alba* subsp. *prasina* as *Nocardiopsis prasina* based on 16S rRNA gene sequences and DNA–DNA hybridization studies.

Cell wall studies carried by Pridham and Lyons (1961) revealed that some *Streptomyces* species did not belong to the genus *Streptomyces* because these strains contained *meso*-DAP. The so-called "*meso*-DAP" streptomycetes were further characterized by Grund (1987). Two members of this group, "*Streptomyces alborubidus*" and "*Streptomyces listeri*", were reclassified in the genus *Nocardiopsis* as *Nocardiopsis alborubida* and *Nocardiopsis listeri* (Grund and Kroppenstedt, 1990). Later, Yassin and co-workers found high similarities between the 16S rRNA gene sequences of *Nocardiopsis alborubida* DSM 40465^T and *Nocardiopsis dassonvillei* (Yassin et al., 1997). As DNA–DNA similarity studies revealed 77% similarity, *Nocardiopsis alborubida* was transferred to *Nocardiopsis dassonvillei* as a later subjective synonym of this species. Later, strain VKM Ac-1882^T (= DSM 40465^T) was reclassified as *Nocardiopsis dassonvillei* subsp. *albirubida* (Evtushenko et al., 2000).

Phylogenetic results based on 16S rRNA gene sequences revealed that members of the genus *Nocardiopsis* represent a distinct lineage apart from all other actinomycetes (Goodfellow et al., 1988; Kroppenstedt et al., 1990; Rainey et al., 1996). Therefore, Rainey et al. (1996) proposed the creation of the family *Nocardiopsaceae*, a member of the suborder *Streptosporangineae* Ward-Rainey et al. 1997, now reclassified as the order *Streptosporangiales*, for the genus *Nocardiopsis*.

Since the last edition of *Bergey's Manual*, the systematics of the genus *Nocardiopsis* has undergone many changes and, at present, the genus harbors 30 species with validly published names; it seems unlikely that current members will suffer further reclassification.

Differentiation of the genus *Nocardiopsis* from other genera

The genus *Nocardiopsis* can be readily separated from the genera *Haloactinospora*, *Streptomonospora*, and *Thermobifida* included in the family *Nocardiopsaceae* and from other closely related genera using a combination of morphological, chemotaxonomic, and 16S rRNA gene sequence phylogenetic data. Differential characteristics of the genus *Nocardiopsis* and closely related taxa are presented in Table 294 in the treatment of the family *Nocardiopsaceae*.

Differentiation of the species of the genus *Nocardiopsis*

Differential characteristics of *Nocardiopsis* species are given in Table 295, although most phenotypic data gathered are based on single isolates.

Acknowledgements

The authors are indebted to Dr J. Meyer and to Dr R.M. Kroppenstedt and Dr L.I. Evtushenko as they drew upon material they wrote for the previous edition of this *Manual* and for *The Prokaryotes*, respectively.

List of species of the genus *Nocardiopsis*

1. **Nocardiopsis dassonvillei** (Brocq-Rousseau 1904) Meyer 1976, 487^{AL} (*Streptothrix dassonvillei* Brocq-Rousseau 1904, 228)

das.son.vil′le.i. N.L. gen. masc. n. *dassonvillei* of Dassonville, named after Charles Dassonville (a French microbiologist and veterinarian at the Pasteur Institute).

Good or abundant growth is found on peptone-glucose medium, oatmeal agar (ISP 3), inorganic salts-starch agar (ISP 4), and Bennett's sucrose agar. Colonies have dense and filamentous margins. The aerial mycelium, when present, is farinaceous, white, or yellowish to grayish. Color of substrate mycelium on the media mentioned is either yellowish-brown or olive-colored to dark brown. Soluble pigments, if produced, are yellowish, greenish-yellow, or brown. Melanoid pigments are not produced on ISP 6 or tyrosine agar (ISP 7).

Aerial mycelium hyphae are long, moderately branched, and, at the beginning of sporulation, more or less zig-zag-shaped (Figure 392). They then divide into long segments that subsequently subdivide into smaller spores of irregular size. Spores are elongated and smooth.

L-Arabinose, D-fructose, D-glucose, glycerol, maltose, D-mannitol, D-mannose, L-rhamnose, sucrose, and D-xylose are utilized as carbon sources. Nitrite may or may not be produced from nitrate. Acid is produced from L-arabinose, galactose, mannitol, L-rhamnose, sucrose, and xylose. Lactate, oxalate, and propionate are decarboxylated. Adenine, casein, DNA, esculin, gelatin, guanine, hypoxanthine, starch, tyrosine, and xanthine are degraded, but testosterone is not. Optimum growth temperature is 28–37°C.

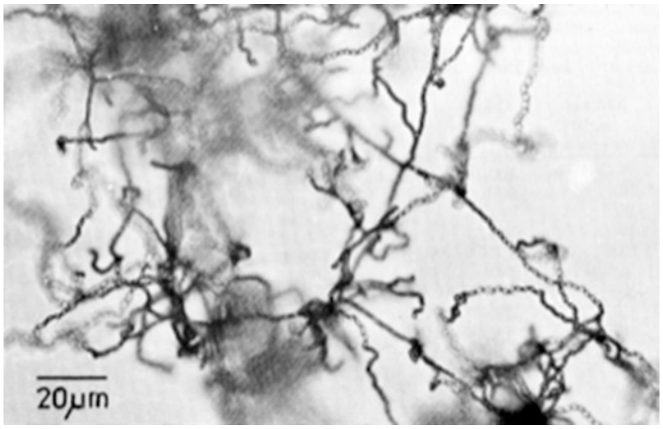

FIGURE 392. *Nocardiopsis dassonvillei* ATCC 23219. Aerial mycelium totally sporulated. Grown on Czapek sucrose agar for 7 d.

Major menaquinones are MK-10(H_6), MK-10(H_4), and MK-9(H_4). Major polar lipids are PME and PC.

Source: the original strain of *Nocardiopsis dassonvillei* was isolated from mildewed grain but this strain was lost. The current type strain was isolated from a case of ocular conjunctivitis.

Type strain: ATCC 23218, DSM 43111, IFO 14626, JCM 7437, NCTC 10488, NRRL B-5397, CIP 107115, IMRU 509, VKM Ac-797.

DNA G+C content (mol%): 69 (T_m).

Sequence accession no. (16S rRNA gene): X97886.

Additional comments: this species currently encompasses two subspecies, *Nocardiopsis dassonvillei* subsp. *dassonvillei* and *Nocardiopsis dassonvillei* subsp. *albirubida*. Yassin et al. (1997) reported that *Nocardiopsis alborubida* corrig. Grund and Kroppenstedt 1990 and *Nocardiopsis antarctica* corrig. Abyzov et al. 1984 were subjective synonyms of *Nocardiopsis dassonvillei* (Brocq-Rousseu 1904) Meyer 1976. Later, Evtushenko et al. (2000) provided evidence for the proposal of the new subspecies, *Nocardiopsis dassonvillei* subsp. *albirubida* comb. nov. (Grund and Kroppenstedt 1990) Evtushenko et al. 2000, and in their paper they corrected the name *alborubida* (*sic*) to *albirubida*.

2. **Nocardiopsis aegyptia** Sabry, Ghanem, Abu-Ella, Schumann, Stackebrandt and Kroppenstedt 2004, 454[VP]

a.e.gyp′ti.a. L. fem. adj. *aegyptia* from Egypt, referring to the country of isolation.

Forms dirty white aerial mycelium, becoming light-yellowish gray in old cultures on glucose-yeast extract-malt extract medium. Hyphae of the aerial mycelium are straight to flexuous. In older cultures, hyphae of aerial mycelium disintegrate into spore-like structures. Short straight chains of spores (0.85 μm diameter) are formed on the aerial mycelium. Spore surface is smooth. No endo- or exopigments are produced.

Grows at 10°C and in 5% (w/v) NaCl, but not at 45°C or in 10% (w/v) NaCl. Optimal growth is obtained on glucose-yeast extract-malt extract agar at 28°C. The following sugars are used as carbon sources: L-arabinose, galactose, glycerol, inositol, D-lactose, mannitol, D-mannose, L-rhamnose, sucrose, and D-xylose.

Polar lipids are PC, PME, PI, PG, and DPG. Major menaquinones are MK-10(H_6), MK-10(H_8), and MK-10(H_4).

Source: the type strain was isolated from marine sediment at a depth of 20 cm on the seashore of Abu Qir Bay, west of Alexandria, Egypt.

Type strain: DSM 44442, JCM 13853, NRRL B-24244, SNG49.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AJ539401.

3. **Nocardiopsis alba** corrig. Grund and Kroppenstedt 1990, 9[VP]

al′ba. L. fem. adj. *alba* white, referring to the white aerial mycelium.

Light yellow substrate mycelium with white aerial hyphae is formed. The spore chains are recti-flexibilis and, in the early stages of sporulation, a zig-zag-shaped aerial mycelium is observed. The best formation of aerial mycelium appears when the organism is grown on Czapek–Dox agar supplemented with yeast extract (2 g/l), Casamino acids (6.1 g/l), and tryptophan (20 mg/l).

Cellobiose, dextrin, fructose, glucose, and sucrose are used as sole carbon sources. Adonitol, arabinose, lactose, melezitose, melibiose, *myo*-inositol, raffinose, rhamnose, sorbitol, and xylose are not utilized. An alkaline reaction is observed with citrate, lactate, malate, and malonate; no alkaline reaction occurs with quinate as the carbon source. Acid production is variable for mannitol. Lactate and propionate are decarboxylated, but not oxalate. Adenine, esculin, hypoxanthine, tyrosine, and xanthine are hydrolyzed. Calcium oxalate crystals are not solubilized. Benzoic acid, salicylic acid, *meta*-hydroxybenzoic acid, and *para*-hydroxybenzoic acid are not degraded. Growth occurs in the presence of 5% (w/v) NaCl, but not in the presence of lysozyme (50 μg/ml). The optimal growth temperature is 28°C; no growth occurs at 45°C.

Major menaquinones are MK-10(H_6), MK-10(H_4), and MK-9(H_4). Major polar lipids are PME and PC.

Source: the type strain was isolated from drainage of a hip.

Type strain: DSM 43377, IFO 15097, JCM 9419, VKM Ac-1883.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): X97883.

Additional comments: the original spelling, *Nocardiopsis albus* subsp. *albus* (*sic*) (orthographically incorrect name), proposed by Grund and Kroppenstedt (1990) has been corrected by Yassin et al. (1997) to *Nocardiopsis alba* subsp. *alba*. After the elevation of the other subspecies of *Nocardiopsis alba*, *Nocardiopsis alba* subsp. *prasina* corrig. (Miyashita et al. 1984) Grund and Kroppenstedt 1990 to full species status as *Nocardiopsis prasina* Yassin et al. 1997 comb. nov., *Nocardiopsis alba* subsp. *alba* corrig. Grund and Kroppenstedt 1990 was simply designated *Nocardiopsis alba* corrig. Grund and Kroppenstedt 1990.

4. **Nocardiopsis alkaliphila** Hozzein, Li, Ali, Hammouda, Mousa, Xu and Jiang 2004, 250[VP]

al.ka.li′phi.la. Arabic article *al* the; Arabic n. *kaïda* soda, saltwort; N.L. n. *alkali* alkali; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. fem. adj. *alkaliphila* loving alkaline environments.

White to yellowish-white aerial mycelium and yellow to yellowish-brown substrate mycelium. Mature aerial mycelium fragments to branched and straight spore-chains with elongated, irregular and smooth spores. Diffusible pigments or melanin are not produced.

Arabinose, cellobiose, maltose, raffinose, sucrose, and xylose are utilized as carbon sources, but weak utilization of dulcitol, glucose, galactose, inositol, lactose, rhamnose, sorbitol, sodium citrate, sodium succinate, and xylitol is observed. Fructose, mannose, mannitol, ribose, and sodium acetate are not used as carbon sources. Growth on potassium nitrate, asparagine, phenylalanine, and serine as nitrogen sources is recorded, but cysteine, glycine, histidine, methionine, threonine, and valine are utilized only weakly, whereas growth on arginine or hydroxyproline is not observed. Casein, gelatin, hypoxanthine, starch, tributyrin, and tyrosine are degraded. Catalase is produced, but not H_2S. Growth occurs at 10–45°C, at pH 7–12, and in 0–10% (w/v) NaCl, with optimum growth at 28–30°C, pH 9.5–10, and 2.5% (w/v) NaCl.

Whole-cell hydrolysates contain the sugars glucose and ribose. Major polar lipids are PC, PG, PME, PE, PIM, an unknown glycolipid, and four unknown phospholipids with high R_f values. Major menaquinones are MK-10(H_6), MK-10(H_8), MK-11(H_2), MK-9(H_6), MK-9(H_{10}), and MK-10(H_4).

Source: the type strain was isolated from desert soil in Egypt.

Type strain: CCTCC AA 001031, DSM 44657, YIM 80379.

DNA G+C content (mol%): 65.8 (T_m).

Sequence accession no. (16S rRNA gene): AY230848.

5. **Nocardiopsis arabia** Hozzein and Goodfellow 2008, 2523[VP]

a.ra′bi.a. L. fem. adj. *arabia* pertaining to Arabia, referring to the isolation of the type strain in Egypt.

Pale-yellow to deep grayish yellow substrate mycelium that carries white aerial hyphae formed on ISP media 1–5. Forms branched substrate mycelium that fragments into coccoid and rod-shaped elements. Aerial hyphae differentiate into straight to flexuous chains of rod-shaped spores with smooth surfaces. Diffusible pigments are not produced.

Arabinose, *meso*-erythritol, D-salicin, and trehalose are used as sole carbon sources, but L-arabitol, melezitose, and xylitol are not. Degrades casein and hypoxanthine, but not adenine, guanine, tyrosine, uric acid, or xanthine. Growth occurs in the presence of NaCl at 0–15% (w/v) (optimally at 5%), and at 10–40°C (optimally at 28°C).

Whole-organism hydrolysates contain the sugars galactose and glucose. The major polar lipids are DPG, PC, PG, PI, PIM, PE, two unknown glycolipids, and two unknown phospholipids with high R_f values. Major menaquinones are MK-10(H_4) and MK-10(H_6).

Source: the type strain was isolated from a sand-dune soil collected at Borg El-Arab, Egypt.

Type strain: CGMCC 4.2057, DSM 45083, S186.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): EF095149.

Additional comments: given the short sequence obtained for *Nocardiopsis arabia* (1377 bp), phylogenetic analyses place this strain within the radiation of the genus *Streptomonospora*; however, morphological and chemical properties are consistent with its assignment to the genus *Nocardiopsis.*

6. **Nocardiopsis baichengensis** Li, Kroppenstedt, Wang, Tang, Lee, Park, Kim, Xu and Jiang 2006, 1095[VP]

bai.cheng.en′sis. N.L. fem. adj. *baichengensis* pertaining to Baicheng, a county of Xinjiang Province in the west of China where the type strain was collected.

Aerial mycelium is white to yellow-white and the substrate mycelium is light yellow to deep orange-yellow. Vegetative hyphae are well developed and fragmented. Long spore chains are borne on the aerial hyphae; these are smooth-surfaced and nonmotile. No diffusible pigments are produced.

L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, glycerol, maltose, D-mannitol, D-mannose, L-rhamnose, D-ribose, sodium acetate, sodium citrate, and sucrose are used as carbon sources, but *myo*-inositol, D-lactose, raffinose, D-sorbitol, starch, D-xylitol, and D-xylose are not. Alanine, arginine, asparagine, glycine, histidine, lysine, phenylalanine, proline, threonine, tryptophan, and valine can be used as sole nitrogen sources, but adenine, cystine, glutamic acid, hydroxyproline, and methionine are not utilized. Milk coagulation, milk peptonization, starch hydrolysis, H_2S production, nitrate reduction, and urease activity are negative, but gelatin liquefaction and melanin production are positive. Optimum growth is at 37–40°C and pH 7.2 with 5–8% (w/v) NaCl. Temperature, pH, and NaCl tolerance ranges are 20–50°C, pH 6–9, and 0–18% NaCl, respectively.

Polar lipids present are PME, PC, PI, PG DPG, and PIM, together with an unknown phosphoglycolipid (PGL) and an unknown phospholipid (PL). Major menaquinones are MK-10(H_2), MK-10(H_4), and MK-10(H_6).

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCTCC AA 2040016, DSM 44845, KCTC 19009, YIM 90130.

DNA G+C content (mol%): 73.2 (T_m).

Sequence accession no. (16S rRNA gene): AY619716.

7. **Nocardiopsis chromatogenes** Li, Kroppenstedt, Wang, Tang, Lee, Park, Kim, Xu and Jiang 2006, 1094[VP]

chro.ma.to′ge.nes. Gr. n. *chroma -atos* color; Gr. v. *gennaio* to produce; N.L. part. adj. *chromatogenes* producing color.

Aerial mycelium is white and the substrate mycelium is light reddish brown to deep reddish brown on most media. Vegetative hyphae are well developed and fragmented. Long spore chains are borne on the aerial hyphae. Spores are smooth-surfaced and nonmotile. Yellowish pink pigments are produced on Czapek agar and inorganic salts-starch agar (ISP 4) media.

L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, glycerol, *myo*-inositol, D-lactose, maltose, D-mannitol, D-mannose, raffinose, L-rhamnose, D-ribose, sodium acetate, sodium citrate, sucrose, and D-xylose are utilized as carbon sources, but D-sorbitol, starch, and D-xylitol are not utilized. Alanine, arginine, asparagine, glycine, histidine, lysine, phenylalanine, proline, threonine, tryptophan, and valine are used as sole nitrogen sources, but adenine,

cystine, glutamic acid, hydroxyproline, and methionine are not utilized. Milk coagulation, milk peptonization, gelatin liquefaction, nitrate reduction, H_2S production, and urease activity are negative, but starch hydrolysis and melanin production are positive. Optimum growth is at 37–40°C and pH 7.2, with 5–8% (w/v) NaCl. Temperature, pH, and NaCl tolerance ranges are 20–60°C, pH 6–9, and 0–18% (w/v), respectively.

The polar lipid profile includes PME, PC, PI, PG, DPG, and PIM, together with an unknown PGL and an unknown PL. Major menaquinones are MK-10, MK-10(H_2), and MK-10(H_4).

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCTCC AA 2040015, DSM 44844, KCTC 19008, YIM 90109.

DNA G+C content (mol%): 71.8 (T_m).

Sequence accession no. (16S rRNA gene): AY619715.

8. **Nocardiopsis composta** corrig. Kämpfer, Busse and Rainey 2002, 627[VP]

com.pos′ta. N.L. fem. adj. *composta* originating from compost.

White aerial mycelium with colorless to brownish-yellow substrate mycelium. Long, branched substrate hyphae fragment into nonmotile elements. Melanin is not produced on CASO agar (casein soy peptone agar).

N-Acetyl-D-glucosamine, L-arabinose, *p*-arbutin, D-fructose, D-galactose, D-glucose, D-mannose, D-ribose, salicin, trehalose, adonitol, *i*-inositol, maltitol, putrescine, acetate, propionate, 4-aminobutyrate, azelate, citrate, fumarate, glutarate, DL-lactate, oxoglutarate, pyruvate, suberate, L-alanine, β-alanine, L-aspartate, L-histidine, L-phenylalanine, L-proline, L-serine, L-tryptophan, and phenylacetate are used as carbon sources. Maltose, L-rhamnose, sucrose, D-xylose, L-malate, mesaconate, L-leucine, and 4-hydroxybenzoate are not used as carbon sources. Degrades esculin, *para*-nitrophenyl (*p*NP)-α-glucopyranoside, *p*NP-β-D-glucopyranoside, L-alanine-*para*-nitroanilide (*p*NA), and L-proline-*p*NA. No growth occurs in NaCl concentrations of 15% or higher. pH values of 6.5–9.5 are tolerated, but no growth occurs at pH 4.5. No growth is observed at a temperature of 10°C, but growth occurs up to 50°C.

Polar lipids present are PME, PC, DPG, PG, and two unknown PLs. Major menaquinones are MK-10(H_8), MK-11(H_8), MK-10(H_6), and MK-12.

Source: the type strain was isolated from the air surrounding a composting facility in Kassel, Germany.

Type strain: DSM 44551, JCM 11768, KS9, NBRC 100345, NRRL B-24145.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AF360734.

Additional comments: the original spelling of the epithet *compostus* (*sic*) has been corrected (List Editor, 2002a). In Latin, *compostus* means brought together, placed together, collected, united, joined, connected, aggregated…, not originating from compost as cited in the paper by Kämpfer et al. (2002).

9. **Nocardiopsis exhalans** Peltola, Andersson, Kämpfer, Auling, Kroppenstedt, Busse, Salkinoja-Salonen and Rainey 2002, 3[VP] (Effective publication: Peltola, Andersson, Kämpfer, Auling, Kroppenstedt, Busse, Salkinoja-Salonen and Rainey 2001, 4302.)

ex.ha′lans. L. part. adj. *exhalans* emitting odors, fumes, toxins, etc.

Yellow vegetative mycelium with white aerial hyphae that are slightly spiral shaped, that fragment to form rod-shaped, nonmotile spores (0.5 µm in diameter). No soluble pigment is produced.

Arabinose, cellobiose, fructose, gluconate, glucose, maltose, mannose, rhamnose, ribose, sucrose, trehalose, xylose, mannitol, putrescine, acetate, *cis*-aconitate, 4-aminobutyrate, azelate, citrate, fumarate, glutarate, 3-hydroxybutyrate, pyruvate, suberate, L-alanine, phenylalanine, proline, serine, 4-hydroxybenzoate, and phenylacetate are used as carbon sources, but not *N*-acetyl-D-glucosamine, arbutin, galactose, melibiose, salicin, adonitol, inositol, maltitol, sorbitol, propionate, adipate, itaconate, lactate, malate, mesaconate, oxoglutarate, β-alanine, aspartate, histidine, leucine, ornithine, tryptophan, or 3-hydroxybenzoate. Esculin is not hydrolyzed. Phosphatase and α-glucosidase are produced. Grows in the presence of 10% (w/v) NaCl; grows at 10, 28, and 37°C, but not at 50°C.

Predominant menaquinones are MK-10(H_6), MK-10(H_8), and MK-10(H_4). The polar lipid profile includes PC, PI, PG, PME, and DPG.

Source: the type strain was isolated from the indoor air of the basement of a water-damaged building of which the occupants suffered from nonspecific health symptoms.

Type strain: DSM 44407, ES10.1, JCM 11759, NBRC 100346, NRRL B-24123.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AY028325.

10. **Nocardiopsis ganjiahuensis** Zhang, Zhang, Yang, Shi, Lu, Chen, Jiang and Xu 2008, 198[VP]

gan.ji.a.hu.en′sis. N.L. fem. adj. *ganjiahuensis* pertaining to Ganjiahu Natural Reserve, Xinjiang, north-west China, where the type strain was isolated.

Gray-white powdery aerial mycelium with light yellow substrate hyphae. The aerial mycelium divides into rod-shaped, irregular-sized spores (0.3–0.5 × 1.0–2.0 µm), which are smooth and nonmotile. The substrate mycelium is long, well-developed, and branched. No diffusible pigments are produced.

L-Arabinose, glycerol, *myo*-inositol, L-rhamnose, and D-xylose are utilized as sole carbon sources, but not cellobiose, lactose, or sucrose. Positive for urease production and nitrate reduction. Tween 80 can be degraded, but not Tween 85. Growth occurs at pH 8.5–13, with optimum at pH 8.5–9.5. No growth at pH 7.0. Grows optimally at 28–32°C; growth occurs at 10°C, with no growth at 42°C. Grows well on media supplemented with 0, 1, 3, and 5% (w/v) NaCl; no growth occurs in 10% NaCl.

Major menaquinones are MK-10(H_2) and MK-10(H_4). Polar lipids are DPG, PC, and PME.

Source: the type strain was isolated from soil.

Type strain: CGMCC 4.3500, DSM 45031, HBUM 20038.

DNA G+C content (mol%): 71.1 (HPLC).

Sequence accession no. (16S rRNA gene): AY336513.

11. **Nocardiopsis gilva** Li, Kroppenstedt, Wang, Tang, Lee, Park, Kim, Xu and Jiang 2006, 1093[VP]

gil′va. L. fem. adj. *gilva* pale yellow.

Aerial mycelium is pale yellow to yellow-white and the substrate mycelium is pale yellow to pale greenish-yellow on media tested. Vegetative hyphae are well developed and fragmented. Spiral spore chains are short and are borne on the aerial hyphae. Spores are smooth-surfaced and nonmotile. No diffusible pigments are produced.

L-Arabinose, cellobiose, D-fructose, D-galactose, D-glucose, glycerol, *myo*-inositol, D-lactose, D-mannitol, raffinose, sodium acetate, sodium citrate, D-sorbitol, starch, sucrose, and D-xylose are used as carbon sources, whereas maltose, D-mannose, L-rhamnose, D-ribose, and D-xylitol are not used. Alanine, arginine, asparagine, glycine, histidine, lysine, proline, and threonine are used as sole nitrogen sources, but adenine, cystine, glutamic acid, hydroxyproline, methionine, phenylalanine, tryptophan, and valine are not used. Milk coagulation, milk peptonization, gelatin liquefaction, starch hydrolysis, H_2S production, urease activity, and melanin production are negative, but nitrate reduction is positive. Optimal growth is at 28–30°C and pH 7.2, with 5–8% (w/v) NaCl. Temperature, pH, and NaCl tolerance ranges are 10–40°C, pH 6–9, and 0–18%, respectively.

The polar lipid pattern contains PME, PC, PI, PG, and DPG. Major menaquinones are MK-11(H_4), MK-11(H_6), and MK-11(H_8).

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCTCC AA 2040012, DSM 44841, KCTC 19006, YIM 90087.

DNA G+C content (mol%): 68.1 (T_m).

Sequence accession no. (16S rRNA gene): AY619712.

12. **Nocardiopsis halophila** Al-Tai and Ruan 1994, 477[VP]

ha.lo′phi.la. Gr. n. *hals halos* salt; Gr. adj. *philos* loving; N.L. fem. adj. *halophila* loving salt.

Cream yellow to coral red substrate mycelium that rarely fragments. Forms a long and extensively branched substrate mycelium. The aerial mycelium is irregularly branched with very long hyphae in zig-zags which fragment into elongated spores with smooth surfaces. No diffusible pigments are produced.

The following carbon sources are used: arabinose, galactose, glucose, fructose, inositol, maltose, mannitol, mannose, raffinose, rhamnose, ribose, sucrose, and xylose. Acid is produced from arabinose, fructose, inositol, maltose, mannitol, ribose, rhamnose, and xylose. Hydrolyzes urea and Tween 80, but does not degrade carboxymethylcellulose, starch, tyrosine, or xanthine. The optimum growth temperature is 30°C. Tolerates NaCl concentrations up to 20% (w/v).

Resistant to lysozyme, amoxycillin, clindamycin, bacitracin, cephalexin, and oxacillin, but susceptible to carbenicillin, chloramphenicol, erythromycin, and novobiocin.

Predominant phospholipids are PC, lyso-DPG, and DPG. Major menaquinones present are MK-10(H_6) and MK-10(H_8).

Source: the type strain was isolated from a saline soil obtained from Iraq.

Type strain: CCIM A.S.4.1195, DSM 44494, IQ-H3, JCM 9892.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AF195411.

13. **Nocardiopsis halotolerans** Al-Zarban, Abbas, Al-Musallam, Steiner, Stackebrandt and Kroppenstedt 2002, 528[VP]

ha.lo.to′le.rans. Gr. n. *hals halos* salt; L. part. adj. *tolerans* tolerating; N.L. part. adj. *halotolerans* salt-tolerating, referring to the ability to tolerate high salt concentrations.

The color of substrate mycelium is beige to brown. Dirty-white to yellow-gray aerial mycelium is formed which shows the typical zig-zag formation prior to sporulation. The long-branched substrate hyphae fragment into nonmotile elements. Diffusible pigments are not produced. Melanin is not observed on either peptone-yeast-iron agar or tyrosine agar (ISP media 6 and 7).

Galactose, glucose, glycerol, D-mannose, melibiose, and sucrose are used as sole carbon sources, but not adonitol, L-arabinose, or D-xylose. Able to degrade feathers. Optimal growth is obtained on starch mineral agar supplemented with 10% (w/v) NaCl at 28°C. Grows at 28–35°C and in NaCl concentrations of 0–15%.

The polar lipid pattern is PC, PI, PG, PME, DPG, and three unknown PLs with high R_f values. The major menaquinones are MK-10, MK-10(H_2), and MK-10(H_4).

Source: the type strain was isolated from salt marsh soil at Al-Khiran, Kuwait.

Type strain: DSM 44410, F100, JCM 11760, NBRC 100347, NRRL B-24124.

DNA G+C content (mol%): 68 (HPLC).

Sequence accession no. (16S rRNA gene): AJ290448.

14. **Nocardiopsis kunsanensis** Chun, Bae, Moon, Jung, Lee and Kim 2000, 1911[VP]

kun.sa.nen′sis. N.L. fem. adj. *kunsanensis* pertaining to Kunsan, a location in Korea where the species was isolated.

Yellow substrate mycelium is formed that bears white aerial hyphae which fragment into elongated nonmotile spores with smooth surfaces. Fragmentation of substrate mycelium has not been observed. Diffusible pigments are not formed.

Utilizes D-glucose and sucrose as sole carbon sources, but not acetate, cellobiose, D-galactose, gluconate, *p*-hydroxybenzoate, *myo*-inositol, maltose, mannitol, paraffin, raffinose, L-rhamnose, or trehalose. L-Alanine is used as sole carbon and nitrogen source, but not gelatin, proline, or serine. Degrades adenine, casein, gelatin, hypoxanthine, starch, tyrosine, urea, and xanthine but not esculin. Nitrate is not reduced to nitrite. H_2S is not produced. Resistant to sodium azide (0.01%), crystal violet (0.0001%), and potassium tellurite (0.0001%); sensitive to phenol (0.1%). Grows optimally at 37°C and pH 9, with 10% (w/v) NaCl.

The polar lipids found are PC, PG, and DPG. Major menaquinone is MK-10(H_8).

Source: the type strain was isolated from a saltern sample collected from Kunsan, Republic of Korea.

Type strain: DSM 44524, HA-9, JCM 10721, KCTC 9831, NBRC 100348.

DNA G+C content (mol%): 71 (T_m).

Sequence accession no. (16S rRNA gene): AF195412.

15. **Nocardiopsis listeri** Grund and Kroppenstedt 1990, 10[VP]

lis′te.ri. N.L. gen. masc. n. *listeri* of Lister, named after Joseph Lister (1827–1912), the father of antiseptic surgery.

Substrate mycelium is colorless and clear in all media tested. Usually no aerial mycelium is formed unless the strain is grown on Hickey–Tresner agar (Hickey and Tresner, 1952), on which a white aerial mycelium is present.

Arabinose, cellobiose, dextrin, fructose, glucose, rhamnose, sucrose, and xylose are used as carbon sources, but not adonitol, *myo*-inositol, lactose, melezitose, melibiose, raffinose, or sorbitol. An alkaline reaction is observed with citrate, lactate, and malate, but not with quinate or malonate. Acid is produced from L-arabinose, galactose, L-rhamnose, and xylose; production from D-lactose and melibiose is variable. Lactate and propionate are decarboxylated, but not oxalate. Adenine, esculin, tyrosine, and xanthine are hydrolyzed, but not calcium oxalate or hypoxanthine. Benzoic acid, salicylic acid, *meta*-hydroxybenzoic acid, and *para*-hydroxybenzoic acid are not degraded.

Growth occurs in the presence of 5% (w/v) NaCl, but not in the presence of lysozyme (50 μg/ml). The optimal growth temperature is 28°C; no growth occurs at 45°C.

Polar lipids present include PC and PME; major menaquinones are MK-10 and MK-10(H_2).

Source: the type strain was isolated from a human clinical specimen.

Type strain: ATCC 27442, CBS 661.72, DSM 40297, IF0 13360, ISP 5297, JCM 4782, KCC S-0782, NCTC 434, RIA 1321, VKM Ac-1881.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): X97887.

16. **Nocardiopsis litoralis** Chen, Wang, Zhang, Tang, Liu, Xiao, Xu, Cui and Li 2009, 2711[VP]

li.to.ra′lis. L. fem. adj. *litoralis* of or belonging to the seashore.

White aerial mycelium and white to yellow-white substrate mycelium with straight to flexuous hyphae are formed. Substrate hyphae are well developed and fragment with age. Long, straight to flexuous spore chains are borne on aerial hyphae, which fragment into elongated nonmotile spores with smooth surfaces. Good growth occurs on most of the media tested. Diffusible pigments or melanin are not produced.

D-Glucose, sucrose, and xylose are used as carbon sources, but L-arabinose, cellobiose, dextrin, D-fructose, D-galactose, D-lactose, maltose, D-mannose, melezitose, melibiose, raffinose, L-rhamnose, D-ribose, D-salicin, trehalose, adonitol, acetate, citrate, gluconate, L-arginine, L-asparagine, L-glutamic acid, glycine, L-histidine, hydroxy-L-proline, L-isoleucine, L-leucine, L-methionine, L-phenylalanine, L-proline, L-serine, L-threonine, and L-valine are not used as carbon sources. Grows optimally at 25°C and pH 8.5, and in the presence of 5–7% (w/v) total salts. No growth is observed in absence of salts. Positive for catalase, but negative for oxidase. Does not reduce nitrate to nitrite. Hydrogen disulfide is not produced. Adenine, gelatin, hypoxanthine, tyrosine, and xanthine are degraded but not casein, cellulose, chitin, DNA, esculin, starch, Tweens 20, 40, 60, and 80, or urea.

The predominant menaquinones are MK-10(H_4), MK-10(H_6), and MK-10(H_8). Polar lipids comprise DPG, PC, and PG.

Source: the type strain was isolated from homogenates of a sea anemone collected from a tidal flat on Naozhou Island in the South China Sea, near Zhanjiang City, Southern China.

Type strain: DSM 45168, JSM 073097, KCTC 19473.

DNA G+C content (mol%): 70.4 (HPLC).

Sequence accession no. (16S rRNA gene): EU583726.

17. **Nocardiopsis lucentensis** Yassin, Galinski, Wohlfarth, Jahnke, Schaal and Trüper 1993, 268[VP]

lu.cen.ten′sis. N.L. fem. adj. *lucentensis* referring to Lucentum, the ancient Latin name of Alicante, a city in Spain, where the type strain was isolated.

The aerial spore mass color is predominantly white. The reverse side of culture growth is yellow to yellowish brown. An extensive substrate mycelium is produced which fragments. Aerial hyphae are branched, long, and well developed on media supplemented with 5–10% (w/v) NaCl and, at the beginning of sporulation, are more or less zig-zag-shaped. The zig-zag-shaped hyphae subdivide into smaller spores which are elongated and have smooth surfaces (Figure 392). Pigments or melanin are not produced. Cultures grow well on both complex and defined media.

The following carbon sources are used on ISP medium 9 supplemented with 5–10% NaCl: D-fructose, glucose, glycerol, *myo*-inositol, maltose, mannitol, mannose, raffinose, rhamnose, sucrose, and trehalose. On the same medium, the following carbon sources are not used: L-arabinose, D-galactose, lactose, and D-xylose. Acid is produced from glucose, inositol, mannitol, raffinose, and rhamnose. Citrate, malate, succinate, acetate, pyruvate, and propionate are decarboxylated, but lactate and oxalate are not. Adenine, hypoxanthine, tyrosine, and xanthine are degraded; casein, starch, gelatin, and esculin are hydrolyzed, but not allantoin, arbutin, or urea. Produces catalase and phosphatase, but not β-galactosidase or β-glucosidase. Nitrate is reduced to nitrite.

Resistant to (μg/ml) gentamicin (64), lincomycin (128), penicillin G (128), neomycin (4), and streptomycin (64), but not to rifampin (128). The organism is susceptible to lysozyme and tolerates NaCl at levels up to and including 10%.

Phospholipids present are PC, PME, PG, and DPG. Major menaquinones include MK-10(H_8), MK-10(H_6), and MK-10(H_{10}).

Source: the type strain was isolated from a soil sample collected in a salt marsh area near Alicante, Spain.

Type strain: A5-1, ATCC 51300, DSM 44048, IFO 15854, JCM 9420, VKM Ac-1962.

DNA G+C content (mol%): 71 (T_m).

Sequence accession no. (16S rRNA gene): X97888.

18. **Nocardiopsis metallicus** Schippers, Bosecker, Willscher, Spröer, Schumann and Kroppenstedt 2002, 2294[VP]

me.tal′li.cus. L. masc. n. *metallicus* the miner, referring to the ability to mobilize metals from slag.

Yellow-brown substrate mycelium bearing white aerial mycelium with straight spore chains.

Acetate, cellobiose, D-galactose, gelatin, gluconate, D-glucose, maltose, mannitol, proline, L-rhamnose, sucrose, trehalose, and D-xylose are used as carbon sources. The pH range for growth is 7.0–10.5 with optimal growth at pH 8.5. Grows well at 30°C, weakly at 10°C, but not at 40°C. Growth occurs on media supplemented with up to 10% (w/v) NaCl.

The polar lipid profile contains DPG, PG, PE, PME, PI, PIM, PC, and unknown PLs with R_f values above DPG.

Source: the type strain was isolated from an alkaline slag dump associated with metallurgical processing in Germany.

Type strain: DSM 44598, JCM 12409, KBS6, NBRC 101841, NRRL B-24159.

DNA G+C content (mol%): 70.8 (HPLC).

Sequence accession no. (16S rRNA gene): AJ420769.

19. **Nocardiopsis potens** Yassin, Spröer, Hupfer, Siering and Klenk 2009, 2732[VP]

po′tens. L. part. adj. *potens* potent, powerful, pertaining to the metabolic activities of the organism.

Pale yellow to brown-yellow substrate mycelium that carries white aerial hyphae is formed on ISP 2–4 agar. Forms a branched substrate mycelium that fragments into coccoid and rod-shaped elements. Aerial hyphae differentiate into straight to flexuous chains of rod-shaped spores with smooth surfaces. Diffusible pigments or melanoid pigments are not produced.

Hydrolyzes casein, elastin, esculin, guanine, hypoxanthine, testosterone, tyrosine, and urea, but not adenine, gelatin, or xanthine. Assimilates acetate, adonitol, adipate, iso-amyl alcohol, L-arabinose, 2,3-butanediol, cellobiose, citrate, *meso*-erythritol, D-galactose, D-gluconate, D-glucose, *myo*-inositol, L-lactate, lactose, maltose, D-mannitol, melezitose, sucrose, and trehalose as carbon sources, but not *m*-hydroxybenzoate, *p*-hydroxybenzoate, 1,2-propanediol, raffinose, L-rhamnose, D-sorbitol, or D-xylose. Utilizes L-alanine, arginine, gelatin, proline, ornithine, and serine, but not acetamide as simultaneous carbon and nitrogen sources. Grows in the presence of 12% NaCl and at 20–37°C, but not at 10 or 42°C.

Major phospholipids are DPG, PC, PG, PI, PIM, and PE. Major menaquinones are MK-11(H_8), MK-11(H_6), MK-11(H_4), MK-11(H_2), MK-10(H_8), MK-10(H_6), MK-10(H_4), MK-10(H_2), MK-9(H_8), MK-9(H_6), MK-9(H_4), and MK-9(H_2).

Source: the type strain was isolated from household waste.

Type strain: CCUG 56587, DSM 45234, IMMIB L-21.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): FM253114.

20. **Nocardiopsis prasina** (Miyashita, Mikami and Arai 1984) Yassin, Rainey, Burghardt, Gierth, Ungerechts, Lux, Seifert, Bal and Schaal 1997, 987[VP] (*Nocardiopsis dassonvillei* subsp. *prasina* Miyashita, Mikami and Arai 1984, 408)

pra.si′na. N.L. fem. adj. prasina (from Gr. adj. *prasina*) leek green (referring to the color of the mature aerial mycelium).

The substrate mycelium is colorless and the aerial mycelium is white to pale pink; a greenish shade is occasionally observed. The sporophore morphology is recti-flexibilis and a zig-zag-shaped aerial mycelium is observed at the beginning of sporulation. Excellent growth and abundant aerial mycelium formation appear at pH 9.0 and above.

Arabinose, cellobiose, dextrin, fructose, glucose, and glycerol are used as carbon sources, but not adonitol, *myo*-inositol, lactose, melezitose, melibiose, raffinose, rhamnose, sucrose, sorbitol, or xylose. An alkaline reaction is observed with citrate, lactate, and malate. No alkaline reaction occurs with quinate or malonate as carbon sources. Acid is produced from galactose, mannitol, and sucrose. Lactate, oxalate, and propionate are decarboxylated. Adenine, esculin, hypoxanthine, and xanthine are hydrolyzed, but tyrosine is not. Benzoic acid, salicylic acid, *meta*-hydroxybenzoic acid, and *para*-hydroxybenzoic acid are not degraded. Growth occurs in the presence of 5% (w/v) NaCl, but not in the presence of lysozyme (50 μg/ml). The optimal growth temperature is 28°C; no growth occurs at 45°C.

Diagnostic phospholipid is PC; major menaquinones are MK-10(H_8), MK-10(H_6), and MK-10(H_4).

Source: the type strain was isolated from soil from Japan.

Type strain: ATCC 35940, DSM 43845, IFO 14423, JCM 3336, VKM Ac-1880.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): X97884.

21. **Nocardiopsis quinghaiensis** Chen, Cui, Kroppenstedt, Stackebrandt, Wen, Xu and Jiang 2008, 703[VP]

quing.hai.en′sis. N.L. fem. adj. *quinghaiensis* pertaining to Qinghai, a province of China in which the sample was collected.

The color of the substrate mycelium is white to pale yellow. Forms white aerial mycelium. Substrate hyphae are well developed and fragment with age. Long spore chains are borne on aerial hyphae. Spores are rod-shaped, smooth, and nonmotile. Diffusible pigments are not produced.

L-Arabinose, cellobiose, citrate, D-fructose, D-glucose, glycerol, *myo*-inositol, D-mannitol, D-mannose, D-ribose, raffinose, sucrose, starch, and trehalose are used as sole carbon and energy sources, whereas acetate, adonitol, D-galactose, D-lactose, maltose, melibiose, D-rhamnose, salicin, D-sorbitol, D-xylitol, and D-xylose cannot be used for growth. L-Alanine, L-asparagine, L-glycine, L-histidine, hydroxy-L-proline, L-methionine, L-proline, L-threonine, and L-tyrosine can be utilized as sole nitrogen sources, whereas adenine, L-arginine, L-cystine, glutamic acid, L-lysine, phenylalanine, L-tryptophan, and L-valine cannot be used. Positive in tests for hydrolysis of casein, chitin, starch, Tween 20, and Tween 80, but negative for hydrolysis of cellulose and gelatin. Nitrate is not reduced to nitrite. H_2S, melanin, and urease are not produced. Optimal growth occurs on marine agar 2216 and Czapek agar with 3% (w/v) NaCl at 28°C and pH 7.0. The temperature, pH, and NaCl concentration ranges for growth are 10–37°C, pH 6.0–8.0, and 0–10%, respectively.

The polar lipid pattern is composed of PC, PG, and DPG. The major menaquinones are MK-10, MK-10(H_2), MK-11(H_2), MK-11, and MK-9(H_4).

Source: the type strain was isolated from a sample of saline soil collected from the Qaidam Basin, Qinghai Province, north-west China.

Type strain: CGMCC 4.3494, DSM 44739, YIM 28A4.

DNA G+C content (mol%): 67.1 (T_m).

Sequence accession no. (16S rRNA gene): EF597511.

22. **Nocardiopsis rhodophaea** Li, Kroppenstedt, Wang, Tang, Lee, Park, Kim, Xu and Jiang 2006, 1094[VP]

rho.do.pha′e.a. Gr. n. *rhodos* the rose; Gr. adj. *phaeos* brown; N.L. fem. adj. *rhodophaea* rose-brown (after the color of the substrate mycelium).

Aerial mycelium is pale pink to light reddish brown and the substrate mycelium is light reddish brown to deep reddish brown on media tested. Vegetative hyphae are well developed and fragmented. Short spore chains are borne on the aerial hyphae. Spores are smooth-surfaced and nonmotile. No diffusible pigments are produced.

L-Arabinose, D-glucose, glycerol, *myo*-inositol, sodium acetate, and D-ribose can be utilized as carbon sources, but not cellobiose, D-fructose, D-galactose, D-lactose, maltose, D-mannose, D-mannitol, raffinose, L-rhamnose, sodium citrate, D-sorbitol, starch, sucrose, D-xylitol, or D-xylose. Alanine, arginine, asparagine, glycine, histidine, proline, and valine are used as sole nitrogen sources, whereas adenine, cystine, glutamic acid, hydroxyproline, lysine, methionine, phenylalanine, threonine, and tryptophan are not utilized. Milk coagulation, gelatin liquefaction, starch hydrolysis, H_2S production, urease activity, nitrate reduction, and melanin production are negative, but milk peptonization is positive. Optimum growth is at 37–40°C and pH 7.2, with 5–8% (w/v) NaCl. Temperature, pH, and NaCl tolerance ranges are 20–60°C, pH 6–9, and 0–18%, respectively.

The polar lipid pattern is composed of PME, PC, PI, PG, DPG, and PIM, together with some unknown PGLs and unknown PLs. Major menaquinones are MK-11(H_6) and MK-11(H_8).

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCTCC AA 2040014, DSM 44843, KCTC 19049, YIM 90096.

DNA G+C content (mol%): 67.1 (T_m).

Sequence accession no. (16S rRNA gene): AY619714.

23. **Nocardiopsis rosea** Li, Kroppenstedt, Wang, Tang, Lee, Park, Kim, Xu and Jiang 2006, 1094[VP]

ro′se.a. L. fem. adj. *rosea* rose colored.

Aerial mycelium is pink-white to pale pink and the substrate mycelium is pale pink to moderate red on media tested. Vegetative hyphae are well developed and fragmented. Spore chains are borne on the aerial hyphae. Spores are smooth-surfaced and nonmotile. No diffusible pigments are produced.

L-Arabinose, D-fructose, D-glucose, D-lactose, maltose, L-rhamnose, D-ribose, sodium acetate, sucrose, and starch can be utilized as carbon sources, but cellobiose, D-galactose, glycerol, *myo*-inositol, D-mannitol, D-mannose, raffinose, sodium citrate, D-sorbitol, D-xylitol, and D-xylose cannot be utilized. Alanine, arginine, asparagine, glycine, histidine, and proline can be used as sole nitrogen sources, but adenine, cystine, glutamic acid, hydroxyproline, lysine, methionine, phenylalanine, threonine, tryptophan, and valine cannot be utilized. Milk coagulation, milk peptonization, gelatin liquefaction, starch hydrolysis, H_2S production, urease activity, and melanin production are negative; nitrate reduction is positive. Optimum growth is at 37–40°C and pH 7.2, with 5–8% (w/v) NaCl. Temperature, pH, and NaCl tolerance ranges are 20–60°C, pH 6–9, and 0–18%, respectively.

The polar lipid pattern is composed of PME, PC, PI, PG, and DPG, together with some unknown PGLs and unknown PLs. Major menaquinones are MK-11, MK-11(H_2), and MK-11(H_4).

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCTCC AA 2040013, DSM 44842, KCTC 19007, YIM 90094.

DNA G+C content (mol%): 67.9 (T_m).

Sequence accession no. (16S rRNA gene): AY619713.

24. **Nocardiopsis salina** Li, Park, Tang, Wang, Lee, Xu, Kim and Jiang 2004, 1808[VP] emend. Li, Kroppenstedt, Wang, Tang, Lee, Park, Kim, Xu and Jiang 2006, 1093

sa.li′na..L. fem. adj. *salina* salty, saline.

The color of the aerial mycelium is white on most media tested and the substrate mycelium is pale yellow to light orange-yellow or yellow-white. The vegetative hyphae are long, well developed, and fragmented. Long or short spore chains are borne on the aerial hyphae. Spores (0.4–0.66 × 8–1.2 µm) are rod-shaped, smooth, and nonmotile. No diffusible pigments are produced.

Fructose, raffinose, ribose, sodium acetate, sodium citrate, and sucrose are utilized as carbon sources, whereas arabinose, cellobiose, galactose, glucose, inositol, maltose, mannitol, melibiose, rhamnose, trehalose, xylitol, and xylose and are not used. Adenine, arginine, asparagine, glycine, histidine, hydroxyproline, hypoxanthine, methionine, phenylalanine, proline, serine, threonine, and valine are used as nitrogen sources. Negative in tests for milk coagulation, milk peptonization, starch hydrolysis, H_2S production, urease activity, and melanin production. Doubtful result for gelatin liquefaction; positive for nitrate reduction. Grows optimally at 28°C and pH 7.2, with 10% (w/v) NaCl; the temperature, pH, and NaCl tolerance ranges are 20–40°C, 6–9, and 3–20% (w/v), respectively.

Polar lipids present are PC, PG, PI, DPG, PE, PME, and four small PL spots above DPG. Main menaquinones include MK-9(H_8) and MK-10(H_8).

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCTCC AA 204009, JCM 13364, KCTC 19003, YIM 90010.

DNA G+C content (mol%): 73.1 (T_m).

Sequence accession no. (16S rRNA gene): AY373031.

25. **Nocardiopsis synnemataformans** Yassin, Rainey, Burghardt, Gierth, Ungerechts, Lux, Seifert, Bal and Schaal 1997, 986[VP]

syn.ne.ma.ta.for′mans. Gr. adv. *syn* together; Gr. n. *nema* thread; N.Gr. n. *synnema* threads wrapping together; L. v.

formare to form; L. pres. part. *formans* forming; N.L. part. adj. *synnemataformans* synnema forming, referring to the ability of the organism to form synnemata.

The substrate mycelium is deep pimento colored, penetrates the agar, and bears aerial mycelia; the aerial mycelium is well developed (0.35–0.45 µm in diameter) with zig-zag or spiral forms and is white with a slight pimento touch, which may be reflected color from the substrate mycelium. Different spirals are wrapped together to form synnemata. The mycelia of a synnema fragment in later stages to form rod-shaped elements. No soluble pigment is produced. Melanoid pigments are not produced on either ISP media 6 or 7.

Cellobiose, citrate, galactose, gluconate, glucose, maltose, mannitol, rhamnose, and xylose are used as carbon sources, but not acetate, adipate, adonitol, arabinose, benzoate, erythritol, *m*-hydroxybenzoate, *p*-hydroxybenzoate, inositol, isoamyl alcohol, lactate, lactose, melezitose, paraffin, raffinose, sorbitol, sucrose, trehalose, 2,3-butanediol, or 1,2-propanediol. Alanine, gelatin, and proline are used as sole carbon and nitrogen sources, but not acetamide or serine. Acid is produced from adonitol, galactose, inositol, D-lactose, mannitol, D-mannose, melibiose, L-rhamnose, and sucrose. Lactate is not decarboxylated. Adenine, casein, elastin, esculin, gelatin, hypoxanthine, tyrosine, urea, and xanthine are hydrolyzed; guanine, keratin, and testosterone are not hydrolyzed. Nitrate reductase, β-glucosidase, β-galactosidase, and phosphatase are produced. Grows in the presence of 10% (w/v) NaCl. Growth occurs at 20, 30, and 37°C but not at 42°C.

Main phospholipids are PC, PE, PG, and DPG. Major menaquinones present are MK-10 and MK-10(H_2).

Source: the type strain was isolated from the sputum of a 35-year-old male who had received a renal transplant.

Type strain: DSM 44143, IMMIB D-1215, JCM 10456, NBRC 102581.

DNA G+C content (mol%): 74.1 (HPLC).

Sequence accession no. (16S rRNA gene): Y13593.

26. **Nocardiopsis trehalosi** nom. rev. (*ex* Dolak, Castle and Laborde 1981) Evtushenko, Taran, Akimov, Kroppenstedt, Tiedje and Stackebrandt 2000, 79[VP] (*Nocardiopsis trehalosei* Dolak, Castle and Laborde 1981)

tre.ha.lo′si. N.L. gen. n. *trehalosi* of trehalose, referring to 3-trehalosamine, an aminoglycoside antibiotic that is produced by the type strain of the species.

The color of the substrate mycelium ranges from pale olive-brownish to pale orange-yellow. The aerial mycelium is white to cream or yellowish gray. Aerial hyphae are zig-zag or twisted-ribbon-like at the beginning of sporulation; spores are irregularly sized (mostly elongated) and have a smooth surface. Long-branched substrate hyphae fragment into nonmotile elements. A light yellow-brownish or light orange-yellow soluble pigment is produced on some media. No melanin is observed on peptone-yeast extract-iron agar (ISP 6).

L-Arabinose, D-fructose, D-galactose, D-glucose, glycerol, lactose, maltose, D-mannitol, D-mannose, L-rhamnose, and D-xylose are used for growth as sole carbon sources, but not adonitol, i-inositol, melibiose, D-sorbitol, or sucrose. Acids are produced from L-arabinose, D-fructose, glycerol, lactose, maltose, D-mannitol, D-mannose, and D-xylose, but not from adonitol, D-galactose, i-inositol, melibiose, L-rhamnose, D-sorbose, or sucrose. Acetate, citrate, formate, fumarate, lactate, malate, malonate, pyruvate, propionate, sebacate, succinate, and tartrate are utilized; no alkaline reaction occurs with aconitate, benzoate, salicylate, or oxalate. Acid is produced from L-arabinose, D-lactose, mannitol, D-mannose, and xylose. Lactate and propionate are decarboxylated, but not oxalate. Casein, calcium oxalate crystals, hypoxanthine, xanthine, Tween 80, and urea are degraded, but not tyrosine, Tween 40, Tween 60, or Tween 85. Esculin hydrolysis is variable. Nitrates are not reduced to nitrites.

Resistant to lysozyme (50 mg/ml). Growth occurs on media supplemented with 5% (w/v) NaCl, 2.5% (v/v) methanol, and 3% (v/v) ethanol, but no growth occurs in 10% (w/v) NaCl or in 0.5% (v/v) butanol. Growth temperature ranges between 18 and 45°C; no growth occurs at 10°C. Optimum growth is at 28–37°C.

Major menaquinones are MK-10(H_4) and MK-10(H_6). Diagnostic phospholipid is PC.

Source: the type strain was isolated from experimental biofilters filled with tree bark compost.

Type strain: CIP 106425, DSM 44380, IFO 14201, JCM 3357, NRRL 12026, VKM Ac-942.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AF105972.

27. **Nocardiopsis tropica** Evtushenko, Taran, Akimov, Kroppenstedt, Tiedje and Stackebrandt 2000, 79[VP]

tro′pi.ca. L. fem. adj. *tropica* tropical, of or pertaining to the tropic(s), referring to the tropical region where the type strain was isolated.

Substrate mycelium is colorless to olive-yellow or red-orange on the different media tested. The aerial mycelium is white; however, it has a cream color on Czapek agar. Aerial hyphae are long and zig-zag shaped at the beginning of sporulation, fragmenting into elongated spore-like structures which subsequently subdivide into short rod-shaped spores of irregular size. Spore surface is smooth. Long-branched substrate hyphae fragment into nonmotile elements. Soluble pigments are yellow-orange to yellow on oatmeal agar or glycerol-nitrate agar. Melanin is not produced on peptone-yeast extract-iron agar (ISP 6).

L-Arabinose, D-fructose, D-galactose, D-glucose, glycerol, maltose, mannitol, D-mannose, melibiose, L-rhamnose, sucrose, and D-xylose are used as sole carbon sources for growth; adonitol, dulcitol, i-inositol, lactose, D-ribose, and D-sorbose are not used. Acids are produced from L-arabinose, D-fructose, D-galactose, D-glucose, glycerol, maltose, D-mannitol, melibiose, L-rhamnose, and sucrose, but not from adonitol, dulcitol, i-inositol, lactose, D-ribose, sorbose, or D-xylose. An alkaline reaction is observed with citrate, formate, fumarate, lactate, malate, malonate, oxalate, propionate, pyruvate, sebacate, succinate, and tartrate, but no alkaline reaction occurs with acetate, aconitate, benzoate, or salicylate. Lactate, oxalate, and propionate are decarboxylated. Xanthine, hypoxanthine, calcium oxalate crystals, urea, and Tweens

40, 60, 80, and 85 are degraded; casein and tyrosine are not. Nitrates are not reduced to nitrites. Growth occurs on media supplemented with 10% (w/v) NaCl, 1.5% (v/v) butanol, 2.5% (v/v) methanol, and 3% (v/v) ethanol, but no growth occurs with 12% (w/v) NaCl or lysozyme (50 mg/ml). Growth occurs at 37°C but not at 10°C or 42°C; optimum growth is between 28 and 30°C.

Major menaquinones are MK-10(H_6) and MK-10(H_8). Diagnostic phospholipid is PC.

Source: the type strain was isolated from soil in the rhizosphere of *Casuarina* sp. (Seychelles).

Type strain: CIP 106426, DSM 44381, JCM 10877, VKM Ac-1457.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AF105971.

28. **Nocardiopsis umidischolae** Peltola, Andersson, Kämpfer, Auling, Kroppenstedt, Busse, Salkinoja-Salonen and Rainey 2002, 3[VP] (Effective publication: Peltola, Andersson, Kämpfer, Auling, Kroppenstedt, Busse, Salkinoja-Salonen and Rainey 2001, 4303).

u.mi.di.scho′la.e. L. adj. *umidus* moist; L. fem. n. *schola* school; N.L. gen. fem. n. *umidischolae* of a moist school.

The vegetative hyphae are yellowish and penetrate the agar. The aerial hyphae are white, 0.2 µm in diameter, and form thick bundles. Soluble pigments are not produced.

Acetate, *cis*-aconitate, aspartate, β-alanine, L-alanine, arabinose, arbutin, 4-aminobutyrate, 3-hydroxybutyrate cellobiose, citrate, fructose, fumarate, galactose, *N*-acetyl-D-glucosamine, gluconate, glucose, glutarate, histidine, lactate, malate, maltitol, maltose, mannitol, mannose, melibiose, oxoglutarate, phenylacetate, phenylalanine, proline, propionate, pyruvate, rhamnose, ribose, serine, sucrose, trehalose, and xylose are used as carbon sources, but not adipate, adonitol, azelate, inositol, 3-hydroxybenzoate, 4-hydroxybenzoate, itaconate, leucine, mesaconate, ornithine, putrescine, salicin, sorbitol, suberate, or tryptophan. Esculin is not hydrolyzed. Produces α- and β-glucosidases, phosphatase, and peptidases. Grows in the presence of 7.5% (w/v) NaCl. Growth occurs at 10, 28, and 37°C, but not at 50°C.

The polar lipid pattern is composed of PC, PI, PG, PME, and DPG. The menaquinone composition includes MK-10(H_6), MK-10(H_4), MK-10(H_8), and MK-10(H_6).

Source: the type strain was isolated from the indoor dust of a water-damaged school.

Type strain: 66/93, DSM 44362, JCM 11758, NBRC 100349, NRRL B-24122.

DNA G+C content (mol%): not determined.

Sequence accession no. (16S rRNA gene): AY036001.

29. **Nocardiopsis valliformis** Yang, Zhang, Guo, Shi, Lu and Zhang 2008c, 1544[VP]

val.li.for′mis. L. n. *vallum* palisade; L. adj. suffix *-formis -is -e* (from L. n. *forma* figure, shape, appearance) like, in the shape of; N.L. fem. adj. *valliformis* shaped like a palisade, referring to the characteristic mycelium, which is often arranged in a shape like a palisade.

Substrate mycelium is yellow to light-brown and is often arranged in a shape like a fence or palisade. Aerial mycelium is abundant and white to yellowish, and fragments into rod-shaped, smooth-surfaced and nonmotile spores (0.3–0.5 × 1.2–2.5 µm). Melanin is not observed on either tyrosine agar or peptone-yeast-iron agar (ISP media 6 and 7).

L-Arabinose, glycerol, lactose, and D-xylose are used as carbon sources, but not *myo*-inositol or sucrose. Nitrate reduction and gelatin liquefaction are positive; H_2S production is negative. Optimal growth temperature is 28°C; no growth occurs at 10, 42 or 45°C. Optimal pH for growth is pH 9.5–13; has a broad range of growth pH, from pH 8.0 to 14.0. No growth at pH 7.0. Growth occurs in the absence of NaCl and in 1, 3, and 5% (w/v) NaCl; no growth in 10% NaCl.

Major phospholipids include DPG and PC. Major menaquinones are MK-10(H_2), MK-10(H_4), and MK-10(H_6).

Source: the type strain was isolated from a soil sample collected from an alkali lake in Xinjiang, China.

Type strain: CGMCC 4.2135, DSM 45023, HBUM 20028.

DNA G+C content (mol%): 70.6 (HPLC).

Sequence accession no. (16S rRNA gene): AY336503.

30. **Nocardiopsis xinjiangensis** Li, Li, Xu, Cui, Xu and Jiang 2003a, 319[VP]

xin.ji.ang.en′sis. N.L. fem. adj. *xinjiangensis* pertaining to Xinjiang, the province of western China in which the sample was collected.

Fragmented substrate and aerial mycelia are well developed on ISP 4, ISP 5, potato agar, and nutrient agar. Short spore chains are borne on the aerial mycelium; spores are rod-shaped with a smooth surface. Diffusible pigments are not produced.

Alanine, cellobiose, galactose, proline, and serine are used as carbon sources, but not glucose, maltose, mannitol, raffinose, rhamnose, sucrose, or xylose. Gelatin liquefaction, urease activity, and melanin production are positive. Milk coagulation, milk peptonization, starch hydrolysis, nitrate reduction, and H_2S production are negative. Optimum growth temperature is 28°C; optimum salt concentration for growth is 10% (w/v); optimum pH for growth is 7.2.

Predominant menaquinones are MK-10(H_2) and MK-10(H_4). Diagnostic phospholipids are PG and PI.

Source: the type strain was isolated from a saline soil sample in the west of China.

Type strain: CCRC 16285, CCTCC AA 99004, DSM 44589, JCM 12328, YIM 90004.

DNA G+C content (mol%): 74.3 (T_m).

Sequence accession no. (16S rRNA gene): AF251709.

Genus II. **Haloactinospora** Tang, Tian, Zhi, Cai, Wu, Yang, Xu and Li 2008, 2078[VP]

Martha E. Trujillo and Michael Goodfellow

Ha.lo.ac.ti.no.spo′ra. Gr. n. *hals halos* salt; Gr. n. *aktis -inos* a ray; Gr. n. *spora* a seed, and in biology, a spore; N.L. fem. n. *Haloactinospora* salt-loving and spored ray, referring to a halophilic and spore-forming actinomycete.

Aerobic, Gram-stain-positive, moderately halophilic filamentous actinomycetes which form well-developed, non-fragmented hyphae. **Long chains of cylindrical spores with smooth surfaces are formed on the aerial mycelium. Short spore chains with wrinkled surfaces and terminal pseudosporangia are formed on the substrate mycelium.** Chemo-organotrophic with an oxidative type of metabolism. **Whole-cell hydrolysates contain *meso*-diaminopimelic acid, galactose, and ribose. Cellular fatty acids are rich in branched, straight-chain, and methyl fatty acids. Major polar lipids are diphosphatidylglycerol, phosphatidylglycerol, phosphatidylcholine, and phosphatidylinositol mannoside.** The predominant menaquinones are MK-10(H_8), MK-11(H_6), and MK-11(H_8).

DNA G+C content (mol%): 68 (HPLC).

Type species: **Haloactinospora alba** Tang, Tian, Zhi, Cai, Wu, Yang, Xu and Li 2008, 2078[VP].

Further descriptive information

Phylogeny. The genus *Haloactinospora* contains one species, *Haloactinospora alba*. The taxon is classified in the family *Nocardiopsaceae*, which also includes the genera *Nocardiopsis*, *Streptomonospora*, and *Thermobifida*. *Haloactinospora alba* forms an independent branch in the 16S rRNA tree between the genera *Streptomonospora* and *Thermobifida*. 16S rRNA gene sequence similarities between *Haloactinospora alba* and members of the family *Nocardiopsaceae* range from 93.3 to 95%. 16S rRNA gene signature nucleotides are consistent with those described for the family *Nocardiopsaceae* (Zhi et al., 2009) (See Figure 389 in the treatment of the family *Nocardiopsaceae*).

Cell morphology. *Haloactinospora alba* forms a well-developed, non-fragmenting substrate mycelium which carries aerial hyphae. Mature aerial hyphae differentiate into long chains of nonmotile cylindrical spores (0.4–0.6 × 1.0–1.2 µm) with smooth surfaces; spore chains with wrinkled surfaces and terminal pseudosporangia are observed on the substrate mycelium (Figure 393).

Nutrition and growth conditions. *Haloactinospora alba* grows well on Czapek's and yeast extract-malt extract agars (ISP 2 medium; Shirling and Gottlieb, 1966); it shows moderate growth on salts-starch, glycerol-asparagine, and nutrient agars, but grows poorly on oatmeal agar (ISP 3 agar; Shirling and Gottlieb, 1966). The color of the aerial mycelium is white to yellow-white and that of the substrate mycelium is pale yellow to light or deep yellow. Diffusible pigments are not produced on any of these media. Temperature, pH, and NaCl tolerance ranges are 20–45°C (optimum 37°C), pH 6–9 (optimum 7–8), and 9–21% (w/v) NaCl (optimum 15%, w/v), respectively.

Cell-wall composition. *Haloactinospora alba* contains *meso*-diaminopimelic acid as the major wall diamino acid. Whole-cell hydrolyzates also contain galactose, ribose, and minor amounts of glucose. The polar lipid pattern of *Haloactinospora alba* YIM 90648[T] includes diphosphatidylglycerol, phosphatidylglycerol, phosphatidylcholine, phosphatidylinositol mannoside, and various unidentified lipids (ninhydrin reagent-positive, Dittmer and Lester reagent-negative); hence, it has phospholipid type III *sensu* Lechevalier et al. (1977, 1981). Menaquinone composition is complex and includes a mixture

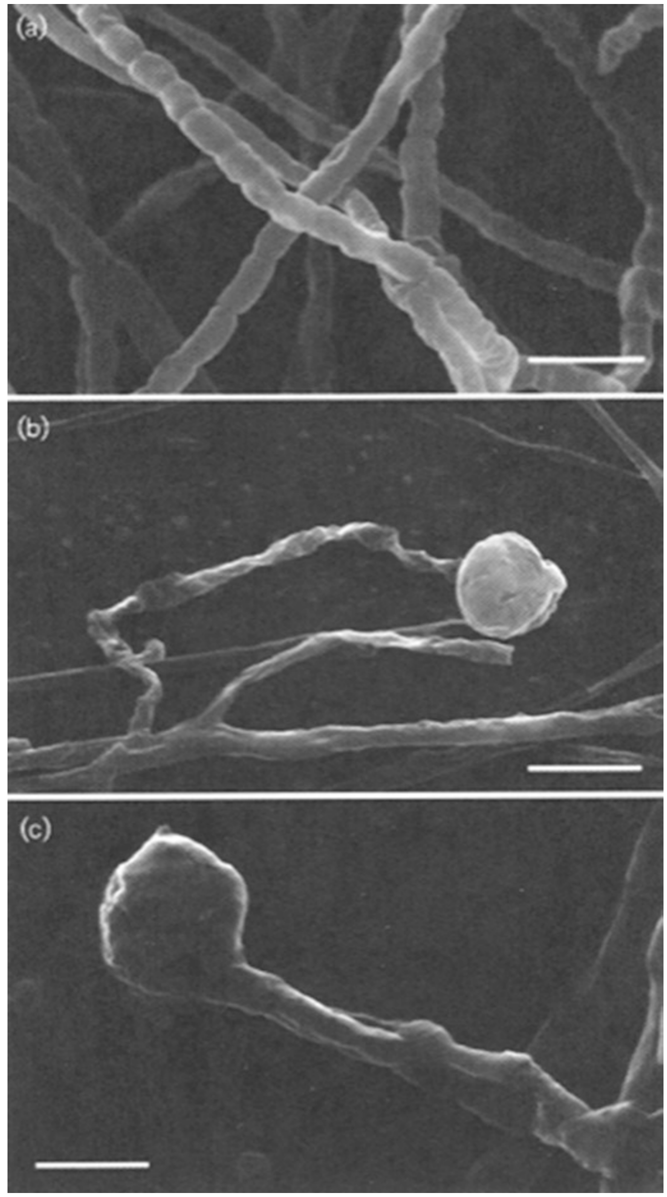

FIGURE 393. Scanning electron micrographs of spore chains and pseudosporangia of *Haloactinospora alba* strain YIM 90648[T] grown on ISP 2 agar supplemented with 15% (w/v) NaCl for 4 weeks at 37°C. (a) Long spore chains on the aerial mycelium; (b, c) substrate mycelium bearing a short spore chain with a terminal pseudosporangium. Bars, 2 µm (a, b) and 1 µm (c). (Reproduced with permission from Tang et al., 2008. Int. J. Syst. Evol. Microbiol. *58*: 2075–2080.)

of MK-10(H_8), MK-11(H_4), MK-11(H_6), and MK-11(H_8), which account for about 52% of the total composition. The fatty acid profile contains major amounts of branched fatty acids and minor amounts of straight-chain and methyl fatty acids; the major fatty acids are 14-methyl-heptadecanoic (iso-16:0) and 14-methyl-hexadecanoic (anteiso-17:0) acids. This fatty acid profile places the organism in fatty acid type 3 d according to Kroppenstedt (1985).

Ecology. The only strain currently representing the genus *Haloactinospora* was isolated from a salt lake in China. Like most members of the family *Nocardiopsaceae*, *Haloactinospora alba* is moderately halophilic; it is likely that additional representatives of this taxon are present in saline habitats.

Isolation procedures

Haloactinospora alba YIM 90648^T was isolated from a salt lake sample by inoculating it onto cellulose-casein-multisalts agar (10 g microcrystalline cellulose, 0.3 g casein, 0.2 g KNO_3, 0.5 g K_2HPO_4, 0.02 g $CaCO_3$, 0.01 g $FeSO_4$, 100 g NaCl, 30 g $MgCl_2 \cdot 6H_2O$, 20 g KCl, and 15 g agar, 1000 ml distilled water). The salts solutions (NaCl, KCl, and $MgCl_2$) should be sterilized separately and added to the medium and the pH should be adjusted to 7.5 with 1 M NaOH. Inoculated plates should be incubated for 3 weeks at 37°C.

Maintenance procedures

Strain YIM 90648^T may be maintained on inorganic salts-starch agar slants (ISP 4 agar; Shirling and Gottlieb, 1966) supplemented with 15% (w/v) NaCl at 4°C for short-term preservation; mycelial fragment suspensions in 20% glycerol (v/v) are recommended for freezing at −25°C.

Differentiation of the genus *Haloactinospora* from other genera

A combination of chemotaxonomic, phenotypic, and phylogenetic procedures can be used to differentiate the genus *Haloactinospora* from related genera. The production of pseudosporangia on substrate mycelium separates *Haloactinospora* from the genera *Nocardiopsis*, *Streptomonospora*, and *Thermobifida*. *Haloactinospora* can be distinguished from the genus *Thermobifida* by differences in growth temperature and tolerance to NaCl. Menaquinone and polar lipid patterns are useful markers for distinguishing between *Haloactinospora* and the three other genera classified in the family *Nocardiopsaceae*. 16S rRNA gene sequencing clearly differentiates *Haloactinospora* from other actinobacterial taxa.

Differentiation of the species of the genus *Haloactinospora*

At present, there is only one species in the genus *Haloactinospora*.

List of species of the genus *Haloactinospora*

1. **Haloactinospora alba** Tang, Tian, Zhi, Cai, Wu, Yang, Xu and Li 2008, 2078^{VP}

al′ba. L. fem. adj. *alba* white.

Aerial and substrate mycelia are well developed and non-fragmented. The color of the aerial mycelium is white to yellow-white and that of the substrate mycelium is pale yellow to light yellow or even deep yellow. Aerial hyphae differentiate into long chains of cylindrical spores which have smooth surfaces. Chains of wrinkled spores with terminal pseudosporangia are formed on the substrate mycelium. Good growth is observed on media supplemented with 15% (w/v) NaCl, notably on Czapek's, yeast extract-malt extract, and potato agars; moderate growth occurs on inorganic salts-starch, glycerol-asparagine agar, and nutrient agars, but growth is poor on oatmeal agar. Diffusible pigments are not produced on these media.

L-Arabinose, D-arabitol, cellobiose, D-fructose, D-galactose, D-glucose, inulin, raffinose, D-ribose, sucrose, D-tagatose, and D-xylose are used as sole carbon sources, but not D-adonitol, D-arabinose, dulcitol, erythritol, glycogen, inositol, D-lactose, maltose, D-mannitol, D-mannose, melezitose, L-rhamnose, L-sorbose, D-sorbitol, trehalose, xylitol, or L-xylose.

Positive for milk peptonization and coagulation. Tests for gelatin liquefaction, production of H_2S and melanin pigments, and for hydrolysis of cellulose, starch and urea are negative.

Temperature, pH, and NaCl tolerance ranges are 20–45°C, pH 6–9, and 9–21% (w/v) NaCl, respectively. Major fatty acids are $C_{16:0}$ iso (23.8%) and $C_{17:0}$ anteiso (36%).

Source: the type strain was isolated from a salt lake in Xinjiang Province, north-west China.

DNA G+C content (mol%): 68 (HPLC).

Type strain: CCTCC AA 206008, DSM 45015, YIM 90648.

Sequence accession no. (16S rRNA gene): DQ923130.

Genus III. **Streptomonospora** corrig. Cui, Mao, Zeng, Li, Zhang, Xu and Jiang 2001, 362^{VP} emend. Li, Xu, Zhang, Tang, Cui, Mao, Xu, Schumann, Stackebrandt and Jiang 2003b, 1424

Xiao-Long Cui

Strep.to.mo.no.spo′ra. Gr. adj. *streptos* pliant, bent; Gr. adj. *monos* single, solitary; Gr. fem. n. *spora* a seed, spore; N.L. fem. n. *Streptomonospora* indicating that this organism forms two types of spores, with wrinkled surfaces, on aerial mycelium and substrate mycelium.

Gram-stain-positive, **aerobic organisms with branching hyphae**, 0.5–0.8 μm in diameter. **Spores are of two types.** The aerial mycelium, at maturity, forms **short chains of nonmotile spores**, which may be oval- to rod-shaped (0.3–1.0 × 0.4–2.0 μm) with wrinkled surfaces. Substrate mycelium is extensively branched with non-fragmenting hyphae. **Single, nonmotile, oval to round spores** (1.4–1.6 μm) are borne on sporophores or dichotomously branched sporophores of substrate hyphae. Optimum

growth occurs in media supplemented with **NaCl at a concentration of 10–15% (w/v), at 28–37°C, and at pH 7.0. Peptidoglycan contains *meso*-diaminopimelic acid as diagnostic diamino acid. Cell walls contain galactose or galactose plus arabinose.** The phospholipid pattern is complex, consisting of phosphatidylglycerol, phosphatidylethanolamine, phosphatidylcholine, phosphatidylinositol, and diphosphatidylglycerol; methylphosphatidylethanolamine, phosphatidylinositol mannosides and phosphatidylserine may occur. The menaquinone composition may depend on the growth medium and consists mainly of menaquinones with nine, ten, or eleven isoprenoid chains and various degrees of hydrogenation. The genus *Streptomonospora* belongs to the family *Nocardiopsaceae* (Rainey et al., 1996). **Inhabit saline environments.**

DNA G+C content (mol%): 71.2–74.4 (HPLC).

Type species: **Streptomonospora salina** corrig. Cui, Mao, Zeng, Li, Zhang, Xu and Jiang 2001, 362[VP].

Further descriptive information

Phylogeny. Based on 16S rRNA gene sequence comparisons of members of the family *Nocardiopsaceae*, members of the genus *Streptomonospora* can be distinguished clearly from those of the genera *Haloactinospora*, *Nocardiopsis*, and *Thermobifida*. The five species currently classified in the genus *Streptomonospora* form two 16S rRNA subclusters: one cluster contains the single species *Streptomonospora halophila*, whereas the second cluster includes the species *Streptomonospora alba*, *Streptomonospora amylolytica*, *Streptomonospora flavalba*, and *Streptomonospora salina* (Figure 394). Both clusters are supported by high bootstrap values indicating significant branch stability. The 16S rRNA gene sequence similarities within the type strains of these species range from 96.7 to 99.6%. In addition, DNA–DNA relatedness values between species tested range from 25.1 to 47.3% (Cai et al., 2009). The signature nucleotides of members of the genus *Streptomonospora*, which differentiate them from those of the other genera in the family *Nocardiopsaceae*, are as follows: 81:88 (G–U), 82:87 (G–C), 185:192 (A–G), 196 (C), 197 (A), 207:212 (G–A), 208 (U), 210 (G), 229 (G), 508 (C), 607 (U), 662:743 (C–G), 998:1043 (G–C), 1025:1036 (U–G), 1026:1035 (G–C), 1042 (G).

Cell morphology and cultural characteristics. Species of the genus *Streptomonospora* produce white to pale yellow colonies with well-developed aerial and substrate hyphae (0.5–0.8 µm in diameter) on nutrient agar, potato agar, Czapek's agar, and most ISP media tested (International *Streptomyces* Project medium; Shirling and Gottlieb, 1966). Species do not produce diffusible pigments on any of these media except for *Streptomonospora flavalba* YIM 91394[T], which produces deep yellow diffusible pigments on potato extract agar (pH 7.0) supplemented with 10% (w/v) NaCl. Morphological observation of 7 to 28-d-old cultures grown on glycerol/asparagine agar (ISP medium 5) or inorganic salt/starch agar (ISP medium 4) containing 10–15% (w/v) NaCl revealed that the vegetative hyphae with irregular branches are well developed, but not fragmented (Figure 395). The aerial mycelium, at maturity, forms short chains of spores that are oval- to rod-shaped (0.3–1.0 × 0.4–2.0 µm) with wrinkled surfaces (Figure 395a). Substrate mycelium is extensively branched with non-fragmenting hyphae. Single spores, which are oval to round and 1.4–1.6 µm in diameter, are borne on sporophores of substrate mycelium or dichotomously branched sporophores, and the surfaces of single spores are wrinkled (Figure 395b). Therefore, there are two types of spores, both of which are nonmotile.

Cell-wall composition. All *Streptomonospora* species contain *meso*-diaminopimelic acid (*meso*-DAP) as the diagnostic amino acid; in addition, *Streptomonospora alba* and *Streptomonospora salina* contain alanine, glutamic acid, muramic acid, acetylglucosamine, and di- and tripeptides typical of peptidoglycan type A1γ (Schleifer and Kandler, 1972). In the initial analysis, Cui et al. (2001) reported that the cell wall of *Streptomonospora salina* YIM 90002[T] contained *meso*-DAP, DD-DAP, glycine, and aspartic acid as cell wall amino acids. A second analysis of the cell wall of this micro-organism (Li et al., 2003b) revealed that the cell-wall composition was similar to that of *Streptomonospora alba*, i.e. peptidoglycan of type A1γ. These authors concluded that the additional amino acids reported previously for *Streptomonospora salina* were probably constituents of a protein tightly attached to the peptidoglycan. All *Streptomonospora* species contain galactose as the diagnostic whole-cell sugar. In addition, *Streptomonospora alba* also contains arabinose. *Streptomonospora alba* YIM 90003[T] and *Streptomonospora salina* YIM 90002[T] have been reported to contain glucose as determined by GC-MS analyses (Chen et al., 2000).

Phospholipid composition. The phospholipid composition of *Streptomonospora* strains is quite complex and varies depending on the species. All strains analyzed contain phosphatidylglycerol, phosphatidylcholine, and phosphatidylinositol. *Streptomonospora alba* and *Streptomonospora salina* also contain phosphatidylethanolamine and methylphosphatidylethanolamine (Cai et al., 2008; Cui et al., 2001; Li et al., 2003b). The former also contains phosphatidylserine. An unidentified phospholipid has also been reported for *Streptomonospora alba*, *Streptomonospora halophila*, and *Streptomonospora salina*. In addition, *Streptomonospora amylolytica*, *Streptomonospora flavalba* (Cai et al., 2009), and *Streptomonospora halophila* contain phosphatidylinositol mannosides.

Quinones. The menaquinone composition may depend on the growth medium and consists mainly of menaquinones with nine, ten, or eleven isoprenoid chains and various degrees of hydrogenation: i.e. a combination of one or more representative(s) of the series [MK-9(H_2), (H_4), (H_6), (H_8)], [MK-10(H_2), (H_4), (H_6), (H_8)], and [MK-11(H_4), (H_6), (H_8), (H_{10})]. Following the procedures of Groth et al. (1999), the predominant menaquinones found in *Streptomonospora alba* YIM 90003[T] grown on vitamin-enriched ISP 2 medium were MK-10(H_2), MK-10(H_4), and MK-9(H_8). The composition changed, however, when cells grown on glucose/yeast extract medium were analyzed: the major menaquinone was MK-9(H_4), whereas MK-9, MK-10(H_4), MK-9(H_2), MK-9(H_6) occurred as minor compounds (Li et al., 2003b). Similar results were obtained when *Streptomonospora salina* YIM 90002[T] was analyzed using cultures grown on different media (Li et al., 2003b). The reason for this change has not been investigated, but medium- and age-dependent shifts in menaquinone composition have been reported previously for *Actinobacteria* (Hiraishi and Komagata, 1989; Saddler et al., 1986).

Fatty acid composition. *Streptomonospora* species contain the following major fatty acids: $C_{17:0}$ anteiso, $C_{16:0}$ iso, $C_{15:0}$ iso, $C_{15:0}$ anteiso, $C_{17:0}$ iso, 10-methyl $C_{17:0}$, $C_{16:0}$, $C_{17:0}$, 10-methyl $C_{18:0}$, $C_{18:0}$, $C_{18:0}$ iso, and $C_{14:0}$ iso.

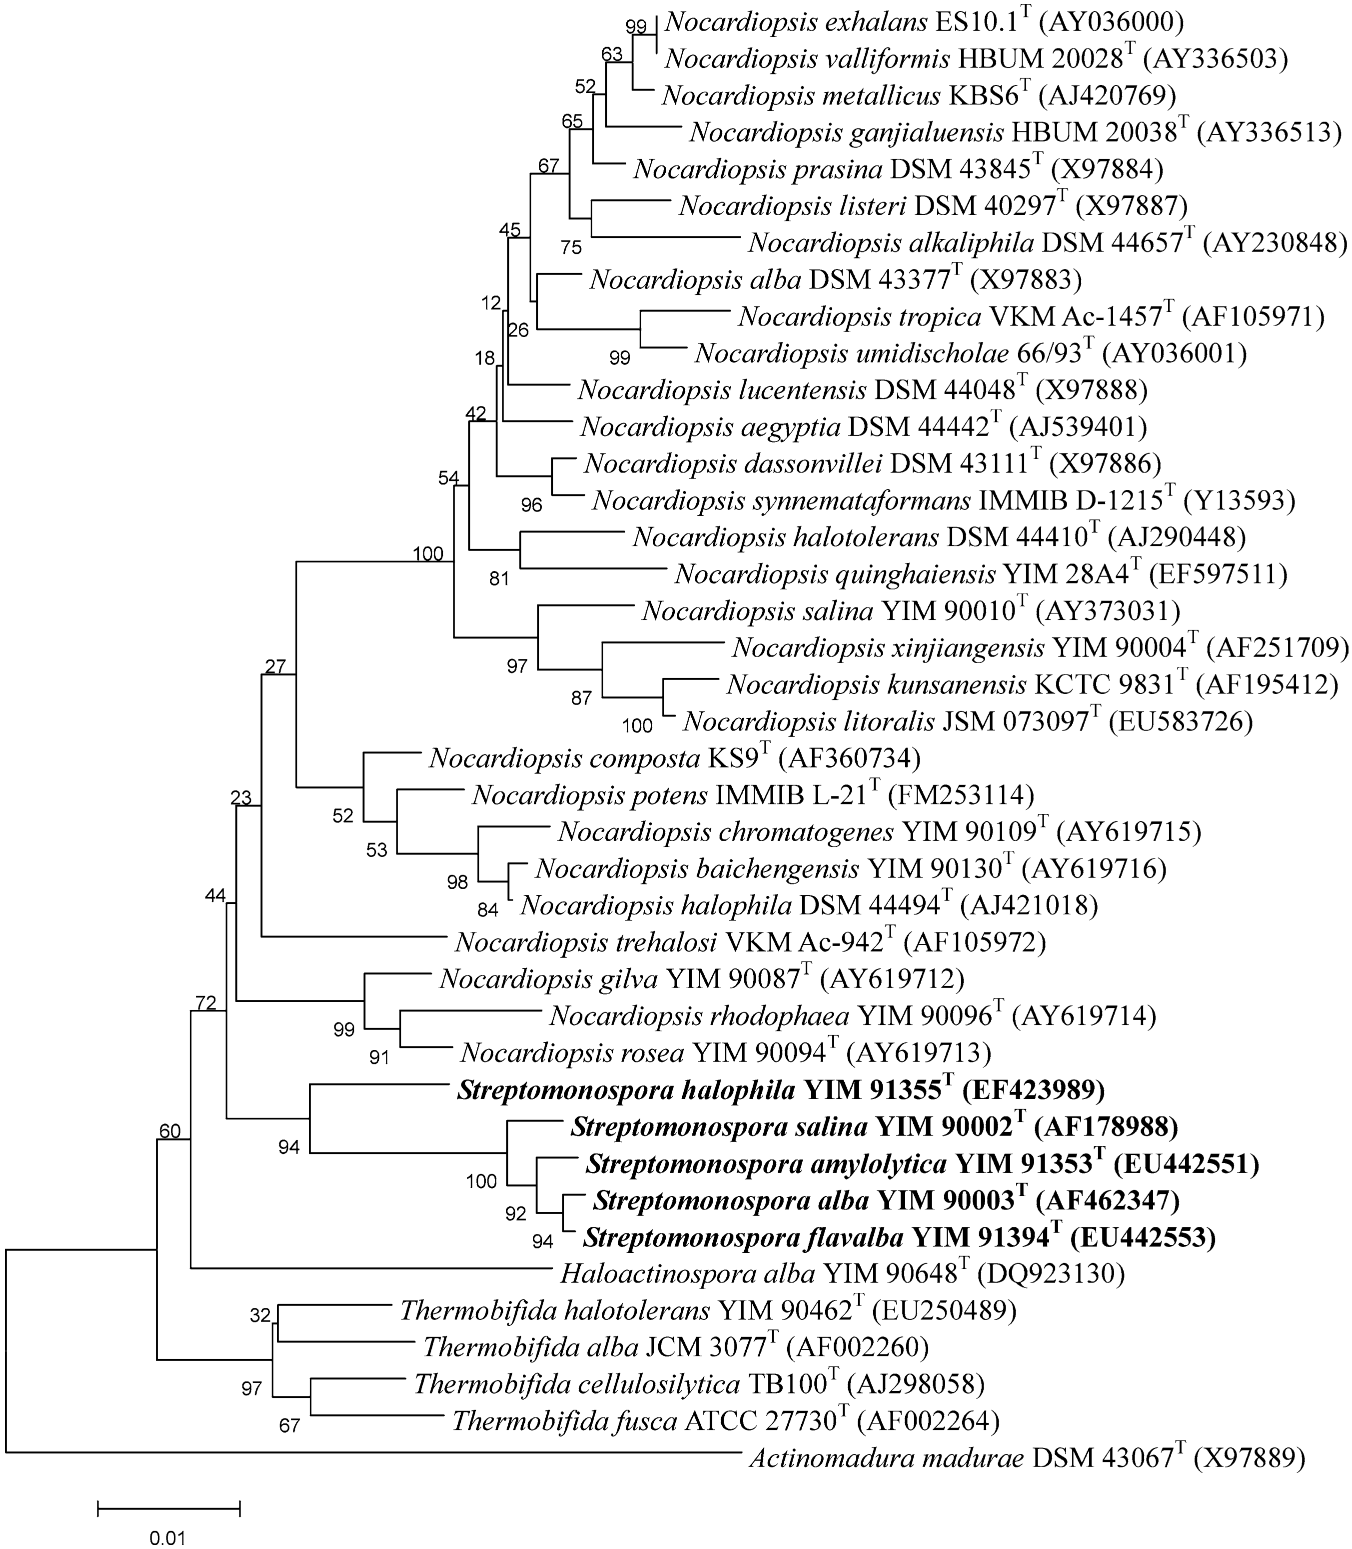

FIGURE 394. Neighbor-joining tree showing the phylogenetic relationships among members of the genera *Streptomonospora*, *Nocardiopsis*, *Haloactinospora*, and *Thermobifida* in the family *Nocardiopsaceae*. *Actinomadura madurae* was used as the outgroup. Bootstrap values from 1000 analyses are shown at the nodes of the tree. Bar = 1 nt substitution per 100 nt of 16S rRNA gene sequence.

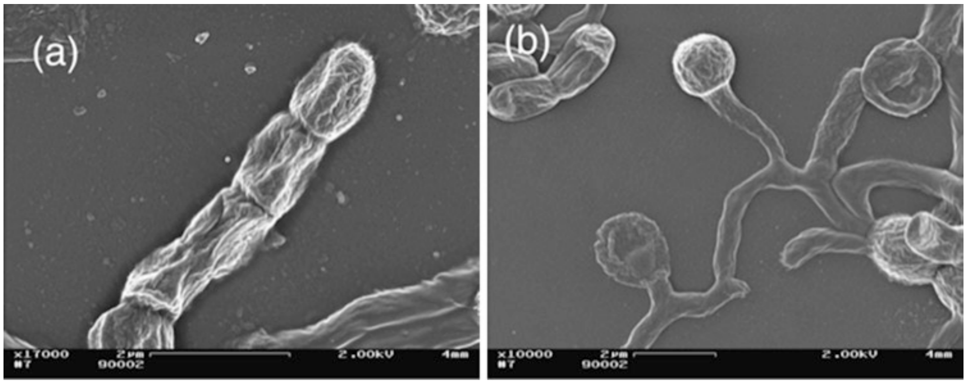

FIGURE 395. Scanning electron micrographs of *Streptomonospora salina* YIM 90002^{T} grown on ISP medium 5 for 28 d at 28°C, showing a short chain of spores (a) and single spores (b). Bars = 2 µm.

Nutrition and growth conditions. Members of the genus *Streptomonospora* are aerobic, heterotrophic, halophilic actinomycetes that require, for optimal growth, complex media adjusted to a pH of 7.0 and supplemented with 10–15% (w/v) NaCl. The optimal growth temperature for *Streptomonospora alba* and *Streptomonospora salina* is 28°C, whereas *Streptomonospora amylolytica*, *Streptomonospora flavalba*, and *Streptomonospora halophila* show optimal growth at 37°C. Good growth is observed on yeast extract/malt extract agar (ISP 2), inorganic salt/starch agar (ISP 4), and glycerol/asparagine agar (ISP 5), and, in most cases, oatmeal agar (ISP 3). *Streptomonospora alba* YIM 90003^{T} grows well on ISP 5 medium, nutrient agar, and Czapek's agar. *Streptomonospora amylolytica* YIM 91353^{T} and *Streptomonospora flavalba* YIM 91394^{T} show good growth on ISP 3 and 2 media, respectively, while both grow well on nutrient agar. *Streptomonospora halophila* YIM 91355^{T} grows very well on modified ISP 5 (Cai et al., 2008). *Streptomonospora salina* YIM 90002^{T} shows good growth on ISP 2 and 5, nutrient agar, Czapek's agar, and potato agar, all supplemented with 15% (w/v) NaCl.

Ecology. All halophilic actinomycetes of the genus *Streptomonospora* have been isolated from hypersaline soil samples from Aiding salt lake in Xinjiang Province in Western China.

Enrichment and isolation procedures

Complex media such as starch/casein agar and modified ISP 5 agar (containing 0.1% K_2HPO_4, 0.1% L-asparagine, 1.0% glycerol, 0.5% yeast extract, 0.5% KNO_3, 10.0% NaCl, 2.0% agar in 1 liter distilled water; pH 7.0) have been used for isolation of *Streptomonospora* strains using dilution plate procedures. Isolation plates are usually incubated at 28 or 37°C for 3 to 4 weeks. Pure cultures may be subsequently obtained on ISP 3 and 4 media, Czapek's agar, potato agar, and nutrient agar, all supplemented with 10–15% (w/v) NaCl.

Maintenance procedures

Streptomonospora cultures may be maintained on ISP 2, ISP 4, and ISP 5 agar slants supplemented with 10–15% (w/v) NaCl at 4°C for short-term preservation. For longer term preservation, all strains can be maintained in 20% (v/v) glycerol suspensions at −80°C. Alternatively, lyophilization is also recommended.

Differentiation of the genus *Streptomonospora* from other genera

Streptomonospora species form two types of spores, which make them easily differentiated from members of the genera *Nocardiopsis*, *Haloactinospora*, and *Thermobifida* of the family *Nocardiopsaceae*. In addition, one set of *Streptomonospora*-specific primers was designed by Zhi et al. (2006, 2007) that can be used to detect/differentiate, by PCR amplification, the large numbers of *Streptomonospora* strains from those of other genera that are obtained from various environments, especially from saline environments.

Taxonomic comments

The genus *Streptomonospora* was first described by Cui et al. (2001) to accommodate a halophilic strain isolated from a salt lake in China; however, the name of the genus was written as "*Streptimonospora*". The original spelling *Streptimonospora* (*sic*) has been corrected by the List Editor, IJSEM (2001), as *Streptomonospora* corrig. Cui et al. 2001, gen. nov.

Differentiation of the species of the genus *Streptomonospora*

Although members of the genus *Streptomonospora* have high 16S rRNA gene sequence similarity values (96.7–99.6%) and share similar morphological properties, low DNA–DNA hybridization values together with differential chemotaxonomic markers, as well as physiological and biochemical characteristics, are useful for differentiating all species (Table 296).

List of species of the genus *Streptomonospora*

1. **Streptomonospora salina** corrig. Cui, Mao, Zeng, Li, Zhang, Xu and Jiang 2001, 362[VP] emend. Li, Xu, Zhang, Tang, Cui, Mao, Xu, Schumann, Stackebrandt and Jiang 2003b, 1424

sa.li′na. L. fem. adj. *salina* salted, saline, referring to the saline habitat of the micro-organism.

White aerial mycelium, at maturity, forms short chains of spores that are oval- to rod-shaped (1.5–2 × 1 µm) with wrinkled surfaces. Mid-yellow substrate mycelium is extensively branched with non-fragmenting hyphae. Single spores, which are oval to round (1.4 × 1.6 µm), are borne on sporophores or dichotomously branched sporophores of substrate hyphae; the surfaces of the spores are wrinkled. Both spore types are nonmotile. Grows in 5–20% (w/v) NaCl. Optimum growth occurs in media supplemented with 15% (w/v) NaCl, at 28°C, and at pH 7.0. Diffusible pigments are not produced.

Glucose, sucrose, maltose, arabinose, raffinose, starch, glycerol, mannitol, and histidine are used as sole carbon sources. Positive for catalase, starch hydrolysis, and melanin production, but negative for oxidase, milk coagulation, peptonization, hydrolysis of cellulose, H_2S production, nitrate reduction, and gelatin liquefaction.

The cell wall contains *meso*-DAP, alanine, glutamic acid, muramic acid, acetylglucosamine, and di- and tripeptides typical of peptidoglycan type A1γ; the cell-wall sugar is galactose. The major menaquinones are MK-10(H_8) (39.4%), MK-10(H_6) (22.6%), and MK-10(H_4) (11.8%). The phospholipid pattern consists of phosphatidylglycerol, phosphatidylinositol, phosphatidylcholine, two methylated phosphatidylethanolamines, and an unidentified phospholipid. The major fatty acids are $C_{15:0}$ iso (30.1%), $C_{16:0}$ iso (16.5%), 9-methyl $C_{16:0}$ (11.7%), and $C_{17:0}$ anteiso (6.7%).

Source: the type strain was isolated from a hypersaline environment (a salt lake in China).

DNA G+C content (mol%): 72.9 (HPLC).

Type strain: YIM 90002, CCRC 16284, CCTCC 99003, DSM 44593.

Sequence accession no. (16S rRNA gene): AF178988.

2. **Streptomonospora alba** Li, Xu, Zhang, Tang, Cui, Mao, Xu, Schumann, Stackebrandt and Jiang 2003b, 1424[VP]

al′ba. L. fem. adj. *alba* white, referring to the color of colonies on most media.

Aerial and substrate mycelia are well developed, but not fragmented on most media. White aerial mycelium forms short chains of spores at maturity that are straight to flexuous; spores are oval- to cylindrical-shaped (0.4–0.7 × 0.8–1.6 µm) with wrinkled surfaces and are nonmotile. Single, round to oval spores are borne on substrate mycelium. Color of the substrate mycelium is white (ISP 4, ISP 5, Czapek's agar), gray-white (ISP 3), moderate orange-yellow (ISP 2), deep orange-yellow (potato agar), or brilliant orange-yellow (nutrient agar). Growth occurs in 5–25% (w/v) NaCl (optimum 10–15%), at 28°C, and at pH 7.0. Diffusible pigments are not produced.

Except for glucose, carbon source utilization is not easy to determine because of negative reactions caused by extremely poor growth in basal media. Positive for catalase and nitrate reduction, but negative for oxidase, starch hydrolysis, milk peptonization, H_2S production, hydrolysis of cellulose, and melanin production.

The diagnostic diamino acid of peptidoglycan is *meso*-DAP, with galactose and arabinose as cell-wall sugars. The predominant menaquinones are MK-10(H_8) (50.6%) and MK-10(H_6) (15.8%). Major phospholipids are phosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, diphosphatidylglycerol, methylphosphatidylethanolamine, phosphatidylserine, phosphatidylcholine, and an unidentified phospholipid. The major fatty acids are $C_{17:0}$ anteiso (26.0%), $C_{16:0}$ iso (25.1%), $C_{16:0}$ (8.6%), and $C_{15:0}$ anteiso (8.0%).

Source: the type strain was isolated from soil in a hypersaline habitat in Xinjiang Province, western China.

DNA G+C content (mol%): 74.4 (HPLC).

Type strain: YIM 90003, CCTCC AA 001013, DSM 44588, JCM 12680.

Sequence accession no. (16S rRNA gene): AF462347.

3. **Streptomonospora amylolytica** Cai, Tang, Chen, Li, Zhang and Li 2009, 2474[VP]

a.my.lo.ly′ti.ca. Gr. n. *amulon* starch; N.L. adj. *lyticus -a -um* (from Gr. adj. *lutikos -ê -on*) able to loosen, able to dissolve; N.L. fem. adj. *amylolytica* producing lysis of starch.

Aerial and substrate mycelia are not fragmented. White to yellow-white aerial mycelia form spore chains at maturity, with nonmotile, oval to cylindrical-shaped spores (0.3–0.4 × 0.4–0.6 µm). Single, oval spores are borne on sporophores of substrate mycelium. Substrate mycelia are yellow-gray on inorganic salt/starch agar, yeast extract/malt extract agar, and oatmeal agar, pale yellow on potato extract agar, and ivory olive brown on nutrient agar medium. Grows well on oatmeal agar and nutrient agar media supplemented with 10% (w/v) NaCl, but no growth occurs on Czapek's agar or glycerol/asparagine agar supplemented with 10% (w/v) NaCl. Diffusible pigments are not produced on any of the media tested. Growth occurs in 5–20% (w/v) NaCl (optimum 10%), at 20–45°C (optimum 37°C), and at pH 5.0–9.0 (optimum pH 7.0).

Arabinose, cellobiose, glucose, rhamnose, and sorbitol are used as sole carbon and energy sources; arginine, hydroxyproline, lysine, proline, threonine, and tryptophan are used as sole nitrogen, carbon, and energy sources. Positive for catalase, hydrolysis of starch, H_2S production, milk coagulation, and peptonization, but negative for oxidase, gelatin liquefaction, hydrolysis of cellulose and urea, melanin production, and nitrate reduction.

The diagnostic amino acid of the cell-wall peptidoglycan is *meso*-DAP and galactose is the major diagnostic sugar in whole-cell hydrolysates. The predominant menaquinones are MK-10(H_8) (35.8%), MK-10(H_6) (16.4%), and MK-9(H_8) (15.3%). The polar lipid profile consists of diphosphatidylglycerol, phosphatidylcholine, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. The major fatty acids are $C_{17:0}$ anteiso (42.4%) and $C_{18:0}$ (11.2%).

Source: the type strain was isolated from saline soil collected from a salt lake in Xinjiang Province, north-west China.

DNA G+C content (mol%): 71.2 (HPLC).

Type strain: YIM 91353, CCTCC AA 208048, DSM 45171.
Sequence accession no. (16S rRNA gene): EU442551.

4. **Streptomonospora flavalba** Cai, Tang, Chen, Li, Zhang and Li 2009, 2474[VP]

fla.val′ba. L. adj. *flavus -a -um* yellow; L. adj. *albus -a -um* white; N.L. fem. adj. *flavalba*, yellowish-white, referring to the color of the aerial mycelium.

Aerial and substrate mycelia are not fragmented. Yellow-white aerial mycelia form spore chains at maturity, with nonmotile, oval to cylindrical-shaped spores (0.5–0.6 × 0.7–0.9 µm). Single, oval spores are borne on sporophores of substrate mycelium. Substrate mycelia are: pale-yellow on inorganic salt/starch agar, oatmeal agar, yeast extract/malt extract agar, glycerol/asparagine agar, and nutrient agar; yellow-white on Czapek's agar; and ivory olive brown on potato extract agar. Growth occurs in 5–25% (w/v) NaCl (optimum 10%), at 20–45°C (optimum 37°C), and at pH 5.0–9.0 (optimum pH 7.0). Grows well on yeast extract/malt extract agar and nutrient agar media supplemented with 10% (w/v) NaCl, but poor growth occurs on Czapek's agar and glycerol/asparagine agar supplemented with 10% (w/v) NaCl. A yellow diffusible pigment is produced on potato extract agar (pH 7.0) supplemented with 10% (w/v) NaCl.

Arabinose, glucose, maltose, and rhamnose are used as sole carbon sources; alanine, arginine, glycine, histidine, phenylalanine, proline, serine, threonine, tryptophan, and tyrosine are used as sole nitrogen, carbon, and energy sources. Positive for catalase, hydrolysis of starch, melanin production, milk coagulation, and peptonization; negative for gelatin liquefaction, hydrolysis of cellulose and urea, H_2S production, nitrate reduction, and oxidase.

The diagnostic amino acid of the cell-wall peptidoglycan is *meso*-DAP and galactose is the major diagnostic sugar in whole-cell hydrolysates. The predominant menaquinones are MK-10(H_8) (41.5%), MK-9(H_8) (27.7%), and MK-10(H_6) (12.6%). The polar lipids consist of diphosphatidylglycerol, phosphatidylcholine, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. The major fatty acids are $C_{17:0}$ anteiso (28.0%) and $C_{16:0}$ iso (24.6%).

Source: the type strain was isolated from saline soil collected from a salt lake in Xinjiang Province, north-west China.

DNA G+C content (mol%): 72.5 (HPLC).

Type strain: YIM 91394, CCTCC AA 208047, DSM 45155.
Sequence accession no. (16S rRNA gene): EU442553.

5. **Streptomonospora halophila** Cai, Zhi, Tang, Zhang, Xu and Li 2008, 1559[VP]

ha.lo′phi.la. Gr. n. *hals halos* salt; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. fem. adj. *halophila* salt-loving, referring to the ability to grow at high NaCl concentrations.

Aerial and substrate mycelia are well developed, but not fragmented. Aerial mycelium forms straight to flexuous spore chains at maturity; spores are oval to cylindrical (0.4–0.5 × 0.8–1.0 µm) and nonmotile. Single, oval to round spores (0.8–1.0 µm diameter) are borne on sporophores of substrate mycelium. Colors of the substrate mycelium are: pale yellow on Czapek's agar, nutrient agar, potato agar, modified ISP 5 medium, and oatmeal agar; pale yellow-white on inorganic salts/starch agar; and yellowish brown on yeast extract/malt extract medium. Diffusible pigments are not produced. Ranges of NaCl concentration (w/v), pH, and temperature for growth are 5–20% (optimum 10%), pH 6.0–9.0 (optimum pH 7.0), and 20–45°C (optimum 37°C), respectively.

Inositol, maltose, and rhamnose are used as sole carbon sources; alanine, histidine, phenylalanine, proline, and threonine are used as sole nitrogen, carbon, and energy sources. Positive for milk peptonization, catalase, and hydrolysis of cellulose, but negative for oxidase, melanin production, amylase, nitrate reduction, and production of H_2S.

The diagnostic amino acid is *meso*-DAP; galactose is the main cell-wall sugar. The predominant menaquinones are MK-10(H_8) (43.2%), MK-10(H_6) (17.7%), and MK-11(H_8) (10.4%). Phospholipids are diphosphatidylglycerol, phosphatidylglycerol, phosphatidylcholine, phosphatidylinositol mannosides, phosphatidylinositol, and an unidentified phospholipid. The major fatty acids are $C_{16:0}$ iso (39.8%), $C_{17:0}$ anteiso (12.5%), 10-methyl $C_{17:0}$ (10.2%), and 10-methyl $C_{18:0}$ (11.1%).

Source: the type strain was isolated from a hypersaline soil in Xinjiang Province, north-west China.

DNA G+C content (mol%): 72.1 (HPLC).

Type strain: YIM 91355, DSM 45075, KCTC 19236.
Sequence accession no. (16S rRNA gene): EF423989.

Genus IV. **Thermobifida** Zhang, Wang and Ruan 1998, 417[VP] emend. Yang, Tang, Zhang, Zhi, Wang, Xu and Li 2008b, 1824

Martha E. Trujillo and Michael Goodfellow

Ther.mo.bi′fi.da. Gr. adj. *thermos* hot; L. adj. *bifidus* cleft; N.L. fem. n. *Thermobifida*, the heat (-loving) cleft (sporophores).

Aerobic, Gram-stain-positive, non-acid-fast, nonmotile, chemoorganotrophic actinomycetes that form an extensively branched, **non-fragmenting substrate mycelium**. **White aerial hyphae are produced. Single spores, oval to round (0.5–2.0 µm in diameter) are borne on dichotomously branched sporophores, resulting in spore clusters on the aerial mycelium and sometimes on the substrate mycelium. Spores have a smooth or scaly surface and may be heat sensitive. Cultures grow at 35–60°C and at pH 7–9. Many strains degrade cellulose**. **Cell walls contains *meso*-diaminopimelic acid**. Glucose, galactose, and xylose are found in whole-organism hydrolysates. **The major menaquinones are MK-10(H_6) and MK-10(H_8) and the predominant fatty acids are 14-methylpentadecanoic and 14-methylhexadecanoic acids**, but mycolic acids are not formed. The polar lipid pattern is

complex and includes diphosphatidylglycerol, phosphatidylcholine, phosphatidylglycerol, phosphatidylinositol, phosphatidylmethylethanolamine, and an unknown phospholipid; the presence of phosphatidylethanolamine is variable. The phylogenetic position of the genus, as determined by 16S rRNA gene sequence analysis, is in the family *Nocardiopsaceae*.

DNA G+C content (mol%): 66–72 (HPLC, T_m).

Type species: **Thermobifida alba** (Locci, Baldacci and Petrolini 1967) Zhang, Wang and Ruan 1998, 418[VP].

Further descriptive information

Phylogeny. The genus *Thermobifida* belongs to the family *Nocardiopsaceae* together with the genera *Haloactinospora* (Tang et al., 2008), *Nocardiopsis*, and *Streptomonospora* (Cui et al., 2001; Yang et al., 2008b). Based on 16S rRNA gene sequences, the four *Thermobifida* species form a homogeneous cluster supported by a high bootstrap value (see Figure 389 in the treatment of the family *Nocardiopsaceae*). *Thermobifida alba* (previously *Thermomonospora alba*), *Thermobifida cellulosilytica*, *Thermobifida fusca* (previously *Thermomonospora fusca*), and *Thermobifida halotolerans* share 16S rRNA gene sequence similarities between 97.5 and 98.2%. The type strains of the four species show DNA–DNA reassociation values between 33 and 50%.

Cell morphology. *Thermobifida* strains form highly branched, non-fragmenting substrate mycelia and produce white aerial mycelium on nutrient agar. Sporulation occurs by septation of sheathed, branched aerial hyphae and this leads to the formation of single spores (Crawford and Gonda, 1977). The latter, which are oval to round (0.5–2.0 µm in diameter), are borne at the tips of repeatedly branched sporophores, and form spore clusters on the aerial mycelium and sometimes on the substrate mycelium (Figure 396). Spore surfaces are smooth in all species, except for *Thermobifida cellulosilytica* where they have a scale-like appearance resembling pine-cones (Figure 397). Heat-sensitive spores have been reported for *Thermobifida alba*, *Thermobifida cellulosilytica*, and *Thermobifida fusca*.

Nutrition and growth conditions. Members of the genus *Thermobifida* are aerobic and chemo-organotrophic. The four type strains grow well on yeast extract-malt extract agar (ISP medium 2) but poorly on oatmeal, inorganic salts-starch and glycerol-asparagine agars (ISP media 3, 4 and 5; Shirling and Gottlieb, 1966); they also grow well on nutrient and potato agar plates. *Thermobifida alba* and *Thermobifida halotolerans* grow between 20 and 50°C, whereas *Thermobifida cellulosilytica* and *Thermobifida fusca* grow between 28 and 60°C. All of the strains grow between pH 6 and 9. Most thermobifidae grow in the presence of 3% NaCl, but *Thermobifida halotolerans* can grow in media containing 10% (w/v) NaCl (Yang et al., 2008b).

Cell-wall composition. *Thermobifida* strains contain *meso*-diaminopimelic acid (*meso*-A_2pm) as the wall diamino acid, but lack diagnostic sugars (Kroppenstedt and Evtushenko, 2006; Yang et al., 2008b), that is, they have a wall chemotype III *sensu* Lechevalier and Lechevalier (1970b). They contain MK-10(H_6) and MK-10(H_8) as predominant menaquinones and additional components, such as MK-10(H_{10}), MK-11(H_6), and MK-11(H_8), which distinguish between the four species (Kroppenstedt and Goodfellow, 1992; Kukolya et al., 2002; Yang et al., 2008b). Differences are also found between the fatty acid profiles of the four species although, in all cases, the major components are 14-methylpentadecanoic acid ($C_{16:0}$ iso) and 14-methylhexadecanoic acid ($C_{17:0}$ anteiso) (Yang et al., 2008b). The cellular polar lipid patterns include diphosphatidylglycerol, phosphatidylcholine, phosphatidylglycerol,

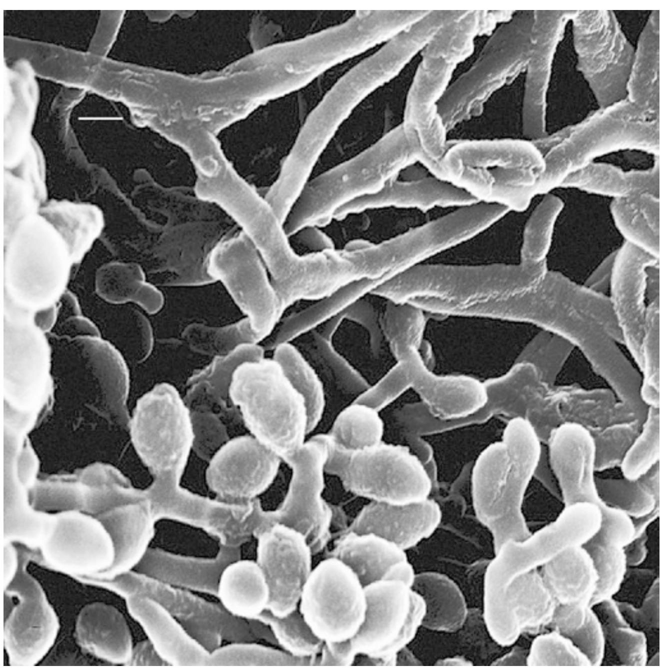

FIGURE 396. Spore formation in *Thermobifida fusca* strain TM51. Bar = 2 µm. (Reproduced with permission from Kukolya et al., 2001. Acta Biol. Hung. *52*: 211–221.)

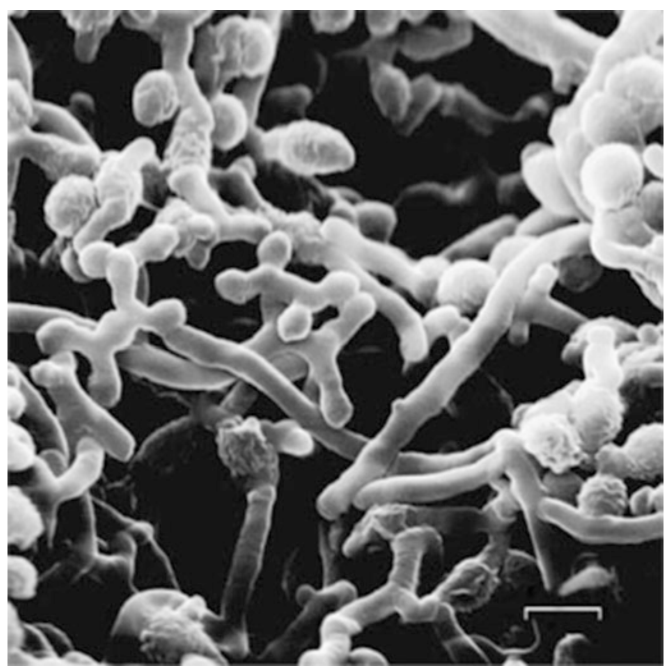

FIGURE 397. Spores of strain *Thermobifida cellulosilytica* TB100[T] formed on aerial hyphae, at the tips of branched sporophores. Bar = 1 µm. (Reproduced with permission from Kukolya et al., 2002. Int. J. Syst. Evol. Microbiol. *52*: 1193–1199.)

phosphatidylinositol, phosphatidylmethylethanolamine, and an unknown phospholipid; *Thermobifida cellulosilytica*, *Thermobifida fusca*, and *Thermobifida halotolerans* also contain phosphatidylethanolamine (Kroppenstedt and Evtushenko, 2006; Yang et al., 2008b). The cell wall of *Thermobifida fusca* contains two teichoic acids, namely, unsubstituted 1,3-poly(glycerol phosphate) and β-glucosylated 1,3-poly(glycerol phosphate) (Potekhina et al., 2003), and a polyglycerophosphate lipoteichoic acid (Rahman et al., 2009).

Metabolism. *Thermobifida* strains are aerobic, catalase-positive, chemo-organotrophic actinomycetes that have an oxidative metabolism. They metabolize a broad range of organic substrates and use diverse sugars as sole carbon sources (Crawford and McCoy, 1972; Kroppenstedt and Evtushenko, 2006; Kukolya et al., 2002; McCarthy and Cross, 1984a; Yang et al., 2008b). Preliminary data suggest that they can cleave a range of 7-amino-4-methylcoumarin and 4-methylumbelliferone-conjugated fluorogenic compounds (Trujillo and Goodfellow, 2003). However, thermobifidae are best known as a source of multiple thermostable enzymes, notably extracellular cellulases (Ball and McCarthy, 1988; Lao et al., 1991; McCarthy, 1987; McGrath and Wilson, 2006; Wilson, 2004) and hemicellulases (McCarthy et al., 1985, 1988).

Thermobifida fusca cellulases have been studied extensively because of their thermostability, broad pH range, and high activity (Beadle et al., 1999; Bellamy, 1973; Irwin et al., 2000; Spiridonov and Wilson, 1998; Wilson, 2004). This organism also has the capacity to degrade plant cell-wall polymers with the exception of lignin. *Thermobifida fusca* YX, a primary degrader of plant cell walls in heated organic matter, grows at 50°C in minimal medium containing cellulose, mannan, starch, or xylan as sole carbon sources and is used as a model system for establishing the complex interactions of glucanases involved in biomass hydrolysis (Warren, 1996).

Extensive studies on *Thermobifida fusca* have led to the identification, purification, and characterization of six extracellular cellulases (Irwin et al., 1993, 1994, 2000, 2003; Wilson et al., 1988; Zhang et al., 1995). In addition, an intracellular β-1,3-glucosidase that degrades cellulose to glucose (Spiridonov and Wilson, 2001), a mannanase (Beki et al., 2003; Hilge et al., 1998, 2001), an extracellular xyloglucanase (Irwin et al., 2003), and the three xylanases (Kim et al., 2004) have been detected, as has the protein CelR, which regulates the induction of cellulases and related enzymes (Wilson, 2004). The structures for three catalytic domains, Cel5Acd, Cel6Acd (Spezio et al., 1993), and Cel9A68 (Sakon et al., 1997), have been elucidated, and the three dimensional structure of *Thermobifida fusca* Cel6A catalytic domain has been determined by X-ray crystallography (Spezio et al., 1993). Components of the *Thermobifida fusca* xylan-degrading system have been purified and characterized (Bachmann and McCarthy, 1989, 1991; Ball and McCarthy, 1989; McCarthy et al., 1985).

The six extracellular enzymes act synergistically to degrade cellulose to cellobiose, traces of cellotriose, and other sugars (Irwin et al., 1993). The released cellobiose is transported into cells where it is converted to glucose by intracellular β-glucosidase (Ball and McCarthy, 1988; Ozaki and Yamada, 1991). Cellulase synthesis in *Thermobifida fusca* is regulated in two ways, induction by cellulose and cellobiose, and carbon source repression (Lin and Wilson, 1987, 1988; Spiridonov and Wilson, 1998). Induction increases cellulase levels about 12-fold and carbon source repression about 9-fold. Other major extracellular proteins induced by cellobiose include a xylanase and two unknown proteins (Chen and Wilson, 2007). *Thermobifida fusca* strains are also very active against arabinoxylan (McCarthy et al., 1985) and can degrade lignocellulosic pulps (Crawford, 1974).

Secreted cellulases are a source of single cell protein (Crawford, 1988; Wood, 1985), while the breakdown of biomass into fermentable sugars has potential for the industrial production of ethanol (Lynd et al., 2002, 2005; Mielenz, 2001; Rubin, 2008). Thermobifidae and other monosporic actinomycetes have been evaluated as a source of single cell protein (Bellamy, 1974, 1977; Crawford, 1988) and ethanol (Ball and McCarthy, 1988; Hägerdahl et al. 1979, 1980; Lee and Humphrey, 1979). Indeed, *Thermobifida fusca* has been used to convert high cellulose, low lignin pulp mill waste into single cell protein (Crawford et al., 1973) that was used as a feed supplement in the diet of chickens (Harkin et al., 1974). The thermostable mannanase produced by this organism has a temperature optimum of 80°C; it hydrolyzes the *O*-glucosidic bonds of mannan and has potential use in pulp and paper production (Hilge et al., 1998; Hilge et al., 2001).

Thermophilic actinomycetes have been used in processes designed to achieve the saccharification of purified cellulose (Bachmann and McCarthy, 1991; Wood, 1985). The cellulases of *Thermobifida fusca* YX, for instance, saccharify finely ground, acid-swollen Avicel, a purified chemically pretreated cellulose (Ferchak, 1980; Su and Paulavicius, 1975). In subsequent studies, Ferchak and Pye (1983) established a process for the saccharification of cellulose using the *Thermobifida fusca* strain and a cellulose/cellobiose mixture; 15–20% glucose syrups were generated from acid-swollen Avicel after 7 d at 50°C. It can be anticipated that the commercial potential of such processes will be improved by the use of cellulase-overproducing *Thermobifida* strains (Meyer and Humphrey, 1982). A composting process for aquatic plants has been developed that involves the use of *Thermobifida fusca* and *Ureibacillus thermosphaericus*, a Gram-stain-negative organism that is unable to ferment sugars (Okuda et al., 2008).

The genome of *Thermobifida fusca* YX has been sequenced (Lykidis et al., 2007), a development that will be of further interest in the metabolism and biotechnological exploitation of this and related organisms. Lykidis and colleagues have shown that the *Thermobifida fusca* genome encodes 45 hydrolytic enzymes, all of the enzymes needed for the glycolytic degradation of monosaccharides and for the biosynthesis of fatty acids, purines and pyrimidines, and enzymes for the *de novo* biosynthesis of all amino acids, apart from arginine. Additionally, glucose utilization is effected through the Entner–Doudoroff pathway. The organism possesses two protein secretion systems, the *sec* general secretion system and the twin-arginine translocation system. Indeed, several of the secreted cellulases have sequence signatures, which indicate that their secretion may be mediated through the twin-arginine translocation system. Extensive transport systems have been detected for import of carbohydrates coupled to transcriptional regulators that control the expression of the transporters and glycosylhydrolases.

Few characterized natural products have been isolated from either archaea or thermophilic bacteria (Donadio et al., 2007).

It is interesting, therefore, that *Thermobifida fusca* YX contains a siderophore biosynthetic gene cluster and has genes that encode a siderophore transport system (Lykidis et al., 2007). This organism also contains a family of structurally related novel nonribosomal peptide siderophores, the fuscachelins, which are products of an orphan gene cluster (Dimise et al., 2008). Fuscachelin A is the first secondary metabolite isolated from *Thermobifida fusca* and the natural product gene cluster is one of only a few detected from a thermophilic micro-organism.

Thermobifida strains produce medically important compounds, as exemplified by the production of topostatin, a novel inhibitor of topoisomerases 1 and 11 (Suzuki et al., 1998a, 1998b). Isoaurastatin, which inhibits topoisomerase 1, has been characterized and shown to be 6,4-dehydroxyisoaurone (Suzuki et al., 2001). A novel non-heme, iron-containing, extracellular peroxidase has been isolated from *Thermobifida fusca* BD25 and its catalytic mechanism has been characterized (Rob et al., 1995, 1996, 1997a, 1997b).

Genetics. In general, genetic studies on *Thermobifida fusca* have been designed to gain an insight into the cellular mechanisms that control the expression and secretion of plant cell wall-degrading enzymes (Wilson, 2004). Genes encoding endoglucanases, exoglucanases, mannosidases, and xylanases have been cloned, sequenced, and expressed in one or more heterologous hosts, namely *Bacillus subtilis* (Ghangas and Wilson, 1987), *Escherichia coli* (Chen and Wilson, 2007; Ghangas et al., 1989; Ghangas and Wilson, 1987, 1988; Irwin et al., 1994, 2000, 2003; Jung et al., 1993; Moser et al., 2008; Spiridonov and Wilson, 2000, 2001), *Streptomyces lividans* (Beki et al., 2003; Ghangas et al., 1989; Ghangas and Wilson, 1988; Irwin et al., 1998, 2000; Zhang et al., 2000; Zhang and Wilson, 1997), and *Pichia pastoris* (Cheng et al., 2005), as a first step towards constructing vehicles for the production of high levels of thermostable enzymes. The xylanase productivity of the *Pichia pastoris* transformant (pPICxXYL) was nearly 70-fold higher than that of the *Thermobifida fusca* strain when cultured in a 5-l fermenter.

Genes encoding two different endo-β-1,4-xylanases have been cloned and expressed in a *Thermobifida alba* strain (Blanco et al., 1997). One of them, *xylA*, was sequenced, subcloned, and overexpressed in *Streptomyces lividans*, and found to encode a protein of 482 amino acids with a deduced molecular mass of 48,456 Da. This protein bound strongly to cellulose and degraded xylans from different origins, producing xylobiose and traces of xylose. There is evidence that chaplin genes are present in *Thermobifida fusca* (Elliot et al., 2003); chaplin amyloids on the surfaces of actinomycetes mediate attachment to hydrophobic surfaces and are responsible for making the surfaces of hyphae and spores hydrophobic (Gebbink et al., 2005).

Thermobifida fusca strains from self-heated organic matter have been found to degrade several diverse biodegradable polyesters, including an aliphatic-aromatic co-polyester (Kleeberg et al., 1998). The gene encoding the *Thermobifida fusca* hydrolase responsible for degrading the co-polyester has been cloned and expressed in *Bacillus megaterium* (Yang et al., 2007b) and *Escherichia coli* (Dresler et al., 2006). In addition, a polyhydroxyalkanoate gene in a *Thermobifida* isolate has been cloned and expressed as a recombinant enzyme (PhaZ-Th) in *Pichia pastoris* (Phithakrotchanakoon et al., 2009). This enzyme is active against *p*-nitrophenyl alkanoates; surface plasmon resonance analysis indicated that PhaZ-Th catalyzed the degradation of poly[(R)-3-hydroxybutyrate] (PHB) films. Surface deterioration of PHB films was observed following exposure to PhaZ-Th by atomic force microscopy.

The genome sequence of *Thermobifida fusca* YX, which consists of a circular chromosome (3.6 Mb), provides the means for elucidating the cellular mechanisms that underpin the metabolism of the organism, including those that control the expression and secretion of cellulases, pectinases, and xylanases (Lykidis et al., 2007). The organism appears to use the TAT secretion system for the export of these enzymes to the extracellular space and produces multiple transcription factors that regulate the expression of glycosylhydrolases and oligo/polysaccharide transport systems. To date, 68% of the 3117 predicted coding sequences have been assigned a function, with 106 genes (3.3%) appearing to be unique to *Thermobifida fusca*. Comparative genome approaches indicate that *Thermobifida fusca* and "*Streptomyces coelicolor*" share a number of developmental genes (Chater and Chandra, 2006; Li et al., 2007; Traag and van Wezel, 2008). *Thermobifida fusca* is one of the few actinobacterial species that does not contain a 5 amino acid insert in glutamyl-tRNA synthase (Gao and Gupta, 2005), an enzyme that plays an essential role in protein synthesis (Woese et al., 2000).

Antibiotic sensitivity. Most *Thermobifida* strains are sensitive to a broad range of antibacterial antibiotics (Kukolya et al., 2002; McCarthy and Cross, 1984a; Trujillo and Goodfellow, 2003) though comparative taxonomic studies on representatives of *Thermobifida* species with validly published names are needed. The antibiotic sensitivity profiles of individual *Thermobifida* species, where known, are provided in the species descriptions.

Pathogenicity. There is no definitive evidence that *Thermobifida* strains, like some other thermophilic actinomycetes, can cause allergic respiratory disorders, though the cause of mushroom workers' disease, a form of allergic alveolitis, is still not settled (Lacey, 1988) It has been claimed that *Thermobifida* aleuriospores may act as allergens (Gusek et al., 1991). In addition, there is evidence that suggests that *Thermobifida alba* and *Thermobifida fusca* may contribute to the occurrence of mushroom workers' lung disease (Van den Bogart et al., 1993).

Ecology. *Thermobifida* strains form an integral part of the authochthonous microflora of overheated plant materials, such as composts, manure heaps, stored hay, and organic household waste (Lacey, 1973; Steger et al., 2007). They are particularly abundant in mushroom composts (Fergus, 1964; Lacey, 1974, 1978; McCarthy and Cross, 1984a, 1984b; McCarthy and Broda, 1984; Song et al., 2001) and in composting anaerobic sludge containing high concentrations of fibers and lipids (Nakasaki et al., 2009). The thermostable, extracellular, cellulolytic (Ball and McCarthy, 1988; McCarthy, 1987), and/or hemicellulolytic (McCarthy et al., 1985, 1988) enzymes produced by *Thermobifida alba* and *Thermobifida fusca* allow them to become dominant in overheated plant materials. *Thermobifida fusca* may be involved in the formation of humic substances in soil (Trigo and Ball, 1994).

Biofilm formation may play a major role in the developmental cycle of *Thermobifida fusca* (Alonso et al., 2008). These workers found that cellulose was specifically colonized by aleuriospores, which germinated, grew, degraded cellulose, and finally differentiated into biofilms encased in a carbohydrate-containing

exopolymeric matrix. Cellulose degradation and expression of *celE*, which encodes endoglucanase E5, was similar for *Thermobifida fusca* biofilms and mycelial pellets. *Thermobifida fusca* cells were also found to grow as biofilms attached to both nutritive and non-nutritive surfaces. Alonso and colleagues speculated that biofilm formation might enable *Thermobifida fusca* to adhere to substrates and obtain nutrients, thereby gaining a selective advantage over competitors in composts. They concluded that *Thermobifida fusca* might prove to be an effective model for filamentous bacterial biofilm research.

Enrichment and isolation procedures

Biocomposted paper (Kempf, 1995), mushroom solid waste compost (Resz et al., 1977; Stutzenberger, 1971), mushroom compost (Fergus, 1964), and self-heated grass cuttings (Kutzner, 2000) are rich sources of *Thermobifida* strains. Isolation of strains from such materials can be achieved by suspending 1 g air-dried sample and 10 g sterile plastic beads in 100 ml Ringer's solution followed by shaking at 180 r.p.m. for 30 min to release spores and mycelial fragments from compost particles. Next, 0.1 ml aliquots of a 10-fold dilution series are plated onto modified starch-casein-nitrate agar plates (Kroppenstedt and Evtushenko, 2006); this medium should be predried to reduce swarming of aerobic, endospore-forming bacilli. Sodium propionate (4 g/l) may be added to the medium to reduce the number of unwanted fast-growing bacteria (Lacey, 1974), although this practice may lead to a reduction in the counts of actinomycetes which form aerial mycelia. *Thermobifida* strains can usually be detected after 3–5 d incubation at 50°C.

Thermobifida strains can be isolated using nonselective agar media, but recovery is poor due to the rapid competing growth of thermophilic aerobic endospore-forming bacilli and thermoactinomycetes. The most effective isolation methods are those based on the use of a sedimentation chamber and Andersen air sampler (Lacey and Dutkiewicz, 1976; McCarthy and Broda, 1984). Dried samples are agitated within the sedimentation chamber to create an aerosol of particles which, after 1–2 h of sedimentation, still contains many actinomycete spores, but comparatively few bacteria. *Thermobifida* strains are isolated from this spore suspension using an Andersen sampler loaded with half-strength tryptone soy agar plates supplemented with cycloheximide (50 µg/ml) to prevent growth of fungi. The inoculated plates are incubated at 50°C for 5 d. The isolation of *Thermobifida* strains may be further improved by adjusting the isolation medium to pH 11.0 (Cross, 1981). Cellulolytic isolates can be identified by incorporating cellulose powder or ball-milled straw into the agar (McCarthy and Broda, 1984; Stutzenberger et al., 1970).

Thermobifida halotolerans was isolated from a salt mine sample after incubation for 3 weeks at 45°C on inorganic salts-starch agar (ISP medium 4; Shirling and Gottlieb, 1966) supplemented with 10% NaCl (Yang et al., 2008b). Putatively novel *Thermobifida* strains have been isolated from mushroom compost on R8 agar plates incubated at 50°C for 3–5 d (Song et al., 2001).

Maintenance procedures

Working cultures of *Thermobifida* can be maintained as sporulating cultures at 4°C for up to 4 months on Czapek–Dox-yeast extract-Casamino acids agar at pH 8.0. Drying out of agar can be prevented by tightly sealing tubes with silicone stoppers. Medium-term preservation for up to 4 years can be achieved by preparing spore suspensions or homogenized mycelia in 20% (v/v) glycerol and storing at −20°C (Wellington and Williams, 1978). For long-term preservation, lyophilization of spores and mycelia suspended in 10% skim milk is a convenient method.

Differentiation of the genus *Thermobifida* from other genera

Thermobifida strains can be readily differentiated from members of the three other genera classified in the family *Nocardiopsaceae* by using a combination of chemotaxonomic, growth, morphological, and physiological properties (Table 297, see also

TABLE 297. Differential characteristics of the type strains of members of the genus *Thermobifida*

Character	*T. alba* DSM 43795^T	*T. cellulosilytica* DSM 44535^T	*T. fusca* DSM 43792^T	*T. halotolerans* YIM 90462^T

treatment of the family *Nocardiopsaceae*) and by 16S rRNA gene sequence studies (see Figure 389 in the treatment of the family *Nocardiopsaceae*). They can be easily separated from their nearest phylogenetic neighbor, the genus *Nocardiopsis*, as members of this taxon form long chains of spores on aerial hyphae and produce a substrate mycelium that tends to fragment. It has also been shown that the genus-specific primers used for PCR identification of *Nocardiopsis* strains do not produce amplification with DNA from *Thermobifida alba* (Salazar et al., 2002).

Taxonomic comments

The taxonomic history of actinomycetes classified in the genus *Thermobifida* as *Thermobifida alba* and *Thermobifida fusca* is complex, confused, and controversial, as is apparent from early reviews on the classification of monosporic actinomycetes (Cross and Lacey, 1970; Cross and Goodfellow, 1973). Indeed, actinomycetes that formed single spores were assigned somewhat unpredictably to a number of taxa, notably to the genera *Actinobifida* Krasil'nikov and Agre 1964, *Micromonospora* Ørskov 1926, *Saccharomonospora* Nonomura and Ohara 1971, *Thermoactinomyces* Tsiklinsky 1899, and *Thermomonospora* Henssen 1957. All of these taxa were essentially morphological in concept. The dangers of over-relying on morphological features was illustrated by Cross and Lacey (1970), who found an almost continuous range of morphological variation between two extremes represented by *Thermomonospora viridis* and *Thermoactinomyces vulgaris*. Between these two extremes, they observed a range of morphological types that overlapped generic boundaries. They also noted that spore arrangement on the aerial mycelium could be influenced by medium composition and incubation temperature.

The rejection of the genus *Actinobifida* as an invalid name (Cross and Goodfellow, 1973; Skerman et al., 1980) and improvements in the classification of the genus *Thermoactinomyces* (Cross and Goodfellow, 1973) helped to define *Thermomonospora* at the genus level. Subsequently, the application of chemotaxonomic and numerical taxonomic methods showed the genus *Thermomonospora* to be a markedly heterogeneous taxon (Kroppenstedt and Evtushenko, 2006; Kroppenstedt and Goodfellow, 1992; McCarthy and Cross, 1984a, 1984b). The detailed taxonomic changes that ensued are presented elsewhere in this volume (see treatment of the family *Thermomonosporaceae*).

Thermomonospora alba DSM 4395^T, the first viable member of the genus *Thermomonospora*, was isolated and described by Locci et al. (1967), who classified it as *Actinobifida alba*. The organism was transferred to the genus *Thermomonospora* as it formed heat-sensitive spores on substrate and aerial hyphae (Cross and Goodfellow, 1973). Subsequently, *Thermomonospora mesouviformis* Nonomura and Ohara 1974 was proposed as a synonym of *Thermomonospora alba* McCarthy and Cross 1984a.

Thermomonospora fusca was proposed on the basis of distinctive morphological properties observed in contaminated preparations (Henssen, 1957). The organism was omitted from the Approved Lists of Bacterial Names (Skerman et al., 1980), even though a *Thermomonospora fusca* strain had been isolated and described in detail (Crawford, 1975; Crawford and Gonda, 1977). *Thermomonospora fusca* was later proposed as a validly published name (McCarthy and Cross, 1984a) and added to the Approved Lists of Bacterial Names (Moore et al., 1985).

Kroppenstedt and Goodfellow (1992) assigned *Thermomonospora* strains to three distinct groups, based on the discontinuous distribution of chemical markers, and raised the prospect that *Thermomonospora alba* (including *Thermomonospora mesouviformis*) and *Thermomonospora fusca* merited generic status. Zhang et al. (1998) found that the type strains of *Thermomonospora alba* and *Thermomonospora fusca* were more closely related to *Nocardiopsis* strains than to other *Thermomonospora* species on the basis of 16S rRNA gene sequence data. These results, together with associated chemotaxonomic and phenotypic data, led them to propose the transfer of *Thermomonospora alba* (Locci et al. 1967) Cross and Goodfellow 1973 and *Thermomonospora fusca* (*ex* Henssen 1957) McCarthy and Cross 1984a to the new genus *Thermobifida* as *Thermobifida alba* Locci et al., 1967 comb. nov. and *Thermobifida fusca* McCarthy and Cross 1984a comb. nov. *Thermobifida alba* was designated the type species of the genus as it had been validated before *Thermobifida fusca* (by Henssen, 1957); *Thermobifida cellulosilytica* Kukolya et al. 2002 and *Thermobifida halotolerans* Yang et al. 2008b were subsequently added to the genus.

Differentiation of the species of the genus *Thermobifida*

Thermobifida species can be distinguished by using a combination of chemotaxonomic, morphological, nutritional, and physiological properties (Table 297). The two most studied species, *Thermobifida alba* and *Thermobifida fusca*, have different temperature and pH requirements (Kroppenstedt and Evtushenko, 2006; McCarthy and Cross, 1984a), give different patterns of enzymes in cell-free extracts (Greiner-Mai et al., 1987), and show quantitative differences in fatty acid profiles (Kroppenstedt and Evtushenko, 2006; Yang et al., 2008b). Additionally, unlike *Thermobifida alba*, most *Thermobifida fusca* strains form spores on the substrate mycelium (McCarthy and Cross, 1984a).

List of species of the genus *Thermobifida*

1. **Thermobifida alba** (Locci, Baldacci and Petrolini 1967) Zhang, Wang and Ruan 1998, 418^{VP} [*Actinobifida alba* Locci, Baldacci and Petrolini 1967, 88; heterotypic synonym: *Thermomonospora mesouviformis* Nonomura and Ohara 1974; basonym: *Thermomonospora alba* (Locci, Baldacci and Petrolini 1967) Cross and Goodfellow 1973.]

   al'ba. L. fem. adj. *alba* white.

   Forms an extensively branched substrate mycelium and abundant white aerial hyphae on agar media. Large numbers of single spores are borne on dichotomously branched or unbranched sporophores on aerial hyphae in dense clusters. Does not produce melanin pigments on tyrosine agar. The optimal temperature for growth and sporulation is 40–45°C; growth occurs at 30°C and at pH 10 and 11.

Positive for esculin, catalase, β-galactosidase, β-glucosidase, and phosphatase, but negative for oxidase. Degrades agar, carboxymethylcellulose, casein, DNA, keratin, pectin, RNA, tributyrin, Tween 60, and xylan, but not guanine, hypoxanthine, testosterone, tyrosine, or xanthine. Variable for elastin. Acid is produced from glucose. Glycogen and mannitol are used as sole carbon sources for energy and growth, but not adonitol, L-arabinose, cellobiose, glucosamine, glycerol, *myo*-inositol, mannitol, melezitose, melibiose, raffinose, or salicin (all at 1%, w/v). Similarly, lactic acid is used as a sole carbon source, but not L-arginine, benzamide, L-cystine, ethanolamine, L-glutamine, glycine, L-histidine, L-lysine, L-phenylalanine, sodium hippurate, sodium propionate, sodium pyruvate, or L-valine.

Grows in the presence of [% (w/v) except where indicated]: bile (0.02), phenol (0.01), phenyl ethanol (0.1, v/v), and thallous acetate (0.001), but is inhibited by brilliant green (0.0005), crystal violet (0.00002), phenol (0.1), phenyl ethanol (0.2%, v/v), potassium tellurite (0.0005), sodium azide (0.01), sodium chloride (3), tetrazolium chloride (0.002), and thallous acetate (0.005). Sensitive to (μg per filter paper disc): ampicillin (5), carbenicillin (25), cephaloridine (2), cephalotin (20), cephamandole (20), kanamycin (25), lincomycin (25), neomycin (3), novobiocin (40), oleandomycin (20), rifampin (1), streptomycin (16), tetracycline (20), and tobramycin (5).

Additional phenotypic properties are shown in Table 297. The major fatty acids are $C_{16:0}$ (24.4%) and $C_{17:0}$ anteiso (29.1%).

Source: the type strain was isolated from garden soil.

DNA G+C content (mol%): 71.2 (HPLC).

Type strain: CIP 105591, DSM 43795, IMET 9528, IPV, JCM 3077, KCCA-0077, NBRC 16095.

Sequence accession no. (16S rRNA gene): AF002260.

Additional comments: cleaves a broad range of fluorogenic substrates based on 7-amino-4-methylcoumarin and 4-methylumbelliferone (Trujillo and Goodfellow, 2003). McCarthy (1989) pointed out that the distinction between *Thermobifida alba* and *Thermobifida mesouviformis* had been maintained only because the latter was regarded as a mesophilic species unable to grow at 50–55°C (Cross, 1981; Kurup, 1979; Nonomura and Ohara, 1974). He also noted that the type strain of *Thermobifida mesouviformis* can show poor growth at 50°C; hence, these species should be considered to be synonymous. However, Kroppenstedt and Evtushenko (2006) believe that DNA–DNA hybridization studies are needed to determine the relationship between the two species. *Thermobifida alba* strains do not form a well-delineated species and may be low-temperature variants of *Thermobifida fusca* (see McCarthy and Cross, 1984a; McCarthy, 1989).

2. **Thermobifida cellulosilytica** corrig. Kukolya, Nagy, Láday, Tóth, Oravecz, Márialigeti and Hornok 2002, 1198[VP]

cel.lu.lo.si.ly′ti.ca. N.L. n. *cellulosum* cellulose; N.L. fem. adj. *lytica* (from Gr. fem. adj. *lutikê*) able to loosen, able to dissolve; N.L. fem. adj. *cellulosilytica* cellulose-dissolving.

Forms an extensively branched substrate mycelium and abundant white aerial hyphae on agar media. Sporophores branch repeatedly to form dense spore clusters on the aerial mycelium. Spores have a scale-like surface, are oval (1–1.3 × 0.6 μm) and heat-sensitive (90°C, 10 min). Thermotolerant strains grow between 28 and 45°C and thermophilic ones between 40 and 65°C.

Degrades crystalline cellulose and elastin. Does not produce acid from glucose. Cellobiose, galactose, melezitose, and xylose are used as carbon sources, but not *myo*-inositol, dulcitol, or sorbitol. Cultures grown on lignocellulose substrate produce endoglucanase, cellobiohydrolase, and endoxylanase enzymes and are capable of solubilizing lignocarbohydrates.

Resistant to (μg/ml) erythromycin (20), but sensitive to amoxycillin (10), ampicillin (10), apramycin (2.5), chloramphenicol (10), kanamycin (2.5), novobiocin (10), penicillin (10) streptomycin (2.5), tetracycline (5), and thistrepton (1.25).

Additional phenotypic characteristics are shown in Table 297. The major fatty acids are $C_{16:0}$ (28.7%), $C_{17:0}$ (26.1%), $C_{17:0}$ anteiso (18.3%), and $C_{18:0}$ (12.4%). The cellular polar lipid pattern includes phosphatidylethanolamine, a glycolipid, and unidentified phospholipids. The predominant menaquinones are MK-10(H_6) and MK-10(H_8); the minor components vary, apart from the presence of MK-11(H_6).

Source: isolated from overheated manure compost in Gödöllö, Hungary.

DNA G+C content (mol%): 70–71 (HPLC).

Type strain: DSM 44535, JCM 11767, NCAIM B0, TB100.

Sequence accession no. (16S rRNA gene): AJ298058.

Additional comments: the original spelling *Thermobifida cellulolytica* (*sic*) was corrected to *Thermobifida cellulosilytica* in Validation List no. 37 by the List Editor, IJSEM (2002b).

3. **Thermobifida fusca** (McCarthy and Cross 1984a) Zhang, Wang and Ruan 1998, 418[VP] (McCarthy and Cross 1984a, 22) [Basonym: *Thermomonospora fusca* (*ex* Henssen 1957) McCarthy and Cross 1984a].

fus′ca. L. fem. adj. *fusca* dark, tawny.

Forms an extensively branched substrate mycelium and abundant white aerial hyphae on agar media. Large numbers of single spores in dense clusters are usually produced on the aerial mycelium. The colony reserve pigment on CYC agar is pale yellow. Does not form melanin pigments on tyrosine agar. Grows at pH 10–11 and at 35–53°C, but not at 30°C; some strains grow at 60°C.

Positive for esculin, catalase, β-galactosidase, β-glucosidase, and phosphatase, but negative for oxidase. Degrades agar, carboxymethylcellulose, casein, elastin, DNA, keratin, pectin, RNA, tributyrin, Tween 60, and xylan, but not chitin, guanine, hypoxanthine, testosterone, tyrosine, or xanthine. Produces acid from glucose. Cellobiose, galactose, glycogen, and melezitose are used as carbon sources for energy and growth, but not adonitol, L-arabinose, glucosamine, *myo*-inositol, mannitol, melibiose, raffinose, or xylose (all at 1%, w/v). Similarly, sodium propionate and sodium pyruvate are used as sole carbon sources, but not L-arginine, benzamide, ethanolamine, L-cystine, L-glutamine, glycine, lactic acid, L-histidine, L-lysine, L-phenylalanine, sodium hippurate, or L-valine.

Grows in the presence of (%, w/v) bile (0.05), crystal violet (0.00002), phenol (0.01), phenyl ethanol (0.2%, v/v), potassium tellurite (0.02), sodium azide (0.01), tetrazolium chloride (0.02), and thallous acetate (0.01), but is inhibited

by phenol (0.1), phenyl ethanol (0.3%, v/v), sodium azide (0.02), tetrazolium chloride (0.005), and thallous acetate (0.005). Sensitive to (µg per filter paper disc): ampicillin (5), carbenicillin (25), cephaloridine (2), cephalothin (20), cephamandole (20), kanamycin (25), lincomycin (10), neomycin (3), novobiocin (10), oleandomycin (20), rifampin (1), streptomycin (4), tetracycline (20), ticarcillin (70), and tobramycin (0.05).

Additional phenotypic characteristics are shown in Table 297. Major fatty acids are $C_{16:0}$ (38.5%) and $C_{17:0}$ anteiso (15.2%).

Source: isolated from composts and overheated fodders. The type strain was isolated from soil.

DNA G+C content (mol%): 66.2 (HPLC).

Type strain: ATCC 27730, CIP 105594, DSM 43792, IFO (now NBRC) 14071, JCM 3263, NCIB 11185, NRRL B-8184, 190 Th, VKM Ac-.

Sequence accession no. (16S rRNA gene): AF002264.

Additional comments: cleaves a broad range of fluorogenic substrates based on 7-amino-4-methylcoumarin and 4-methylumbelliferone (Trujillo and Goodfellow, 2003). *Thermobifida fusca* was not originally isolated in pure culture (Henssen, 1957) and the unavailability of cultures led to the species being cited as a *nomen dubium* in the 8th edition of the *Manual*. Furthermore, a wholly inaccurate description of *Thermobifida fusca* Henssen, given by Waksman (1961a), led to the use of this name for strains that probably belong to *Thermomonospora chromogena* (Cross and Lacey, 1970; Fergus, 1964; Locci et al., 1967; Nonomura and Ohara, 1969). This conclusion was removed by the subsequent description of what is now the type strain of *Thermobifida fusca* Crawford 1975, although this did not result in validation of the name. Proposals that *Thermobifida fusca* Crawford 1975 be regarded as a synonym of *Thermobifida alba* Cross 1981 or vice versa (Kurup, 1979) are not in agreement with numerical phenetic data (McCarthy and Cross, 1984a), as the respective type strains were recovered in separate clusters.

4. **Thermobifida halotolerans** Yang, Tang, Zhang, Zhi, Wang, Xu and Li 2008b, 1824[VP]

ha.lo.to′le.rans. Gr. n. *hals halos* salt; L. part. adj. *tolerans* tolerating; N.L. part. adj. *halotolerans* referring to the ability to tolerate high salt concentrations.

Forms an extensively branched substrate mycelium and grows well on nutrient, potato, and glucose-yeast extract-malt extract agars, but does not grow on Czapek's agar. Single, smooth-ridged spores are formed at the tips of dichotomously branched sporophores borne on aerial hyphae. Does not form melanin pigments on tyrosine agar. Grows well at 45°C and at pH 7.0 and 8.0. Cellobiose, galactose, glucose, glycerol, raffinose, and xylose are used as sole carbon sources for energy and growth, but not *myo*-inositol or sorbitol.

Additional characteristics are found in Table 297. Diagnostic sugars are glucose, galactose, and xylose. Major fatty acids are $C_{16:0}$ iso (51.1%) and $C_{17:0}$ anteiso (11.7%). The cellular polar lipid pattern contains diphosphatidylglycerol, phosphatidylcholine, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, phosphatidylmethylethanolamine, and an unknown phospholipid. The predominant menaquinones are MK-9(H_6) and MK-10(H_8).

Source: the type strain was isolated from a saline soil sample collected in Yunnan Province, south-west China.

DNA G+C content (mol%): 69.0 (HPLC).

Type strain: DSM 44931, KCTC 3, YIM 90462.

Sequence accession no. (16S rRNA gene): EU250489.

Family III. **Thermomonosporaceae** Rainey, Ward-Rainey and Stackebrandt 1997, 486[VP] emend. Zhang, Wang and Ruan 2001, 381 emend. Zhi, Li and Stackebrandt 2009, 600

Michael Goodfellow and Martha E. Trujillo

Ther.mo.mo.no.spo.ra.ce′a.e. N.L. fem. n. *Thermomonospora* type genus of family; L. suff. *-aceae* ending to denote family; N.L. fem. pl. n. *Thermomonosporaceae*, the *Thermomonospora* family.

Aerobic, Gram-stain-positive, non-acid–alcohol-fast, chemoorganotrophic actinomycete. A stable, branched substrate mycelium carries an aerial mycelium. **Aerial hyphae differentiate into single or short chains of arthrospores or into spore vesicles which release motile spores**. **Wall peptidoglycan contains *meso*-diaminopimelic acid**, ***N*-acetylmuramic acid and is of the A1γ type**. **Major phospholipids are phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides**. **Contains hydrogenated menaquinones with nine isoprene units**. Rich in mixtures of straight chain and branched fatty acids. Lacks mycolic acids. **Whole-organism hydrolysates usually contain madurose**. The pattern of 16S rRNA signatures consists of nucleotides at positions 440:497 (C–G), 501:544 (C–G), 502:543 (G–C), 831:855 (G–G), 843 (U), 844 (A), and 1355:1367 (A–U) (Zhi et al., 2009). A few species are pathogenic for animals, including man. Widely distributed in composts, manures, overheated fodder, and soil.

DNA G+C content (mol%): 66–73.

Type genus: **Thermomonospora** Henssen 1957, 398[AL] emend. Zhang, Wang and Ruan 1998b, 418.

Further descriptive information

The family *Thermomonosporaceae* (Rainey et al. 1997) emend. Zhang et al. 2001 encompasses the genera *Actinocorallia* (Iinuma et al. 1994) emend. Zhang et al. 2001, *Actinomadura* (Lechevalier and Lechevalier 1970a) emend. Kroppenstedt et al. 1990, *Spirillospora* Couch 1963, and *Thermomonospora* (Henssen 1957) emend. Zhang et al. 2001. Members of these taxa form a distinct phyletic line in the 16S rRNA gene tree (Zhang et al., 1998b, 2001) and can thereby be distinguished from the families *Nocardiopsaceae* and *Streptosporangiaceae* (Goodfellow and Quintana, 2006; Goodfellow et al., 1990; Gyobu, 2001; Kudo, 2001), the other two families that comprise the suborder *Streptosporangineae* Rainey et al. 1997. *Actinomadura*, *Spirillospora*, and *Thermomonospora* strains are phylogenetically intermixed as can be seen in the *Thermomonosporaceae* 16S rRNA gene tree (Figure 398).

Differentiation of the genera of the family *Thermomonosporaceae*

Members of the genera *Actinocorallia*, *Actinomadura*, *Spirillospora*, and *Thermomonospora* can be distinguished from one another using a combination of chemotaxonomic and morphological markers (Table 298).

Taxonomic comments

Cross and Goodfellow (1973) proposed the family *Thermomonosporaceae* for a morphologically diverse group of sporoactinomycetes classified in the genera *Actinomadura*, *Microbispora*, *Microtetraspora*, *Saccharomonospora*, and *Thermomonospora*. They recognized that the taxon was an artificial construct, but also noted that the constituent genera had more in common than the assortment of taxa assigned to the family *Nocardiaceae*, a well known dumping ground for aerobic actinomycetes (Lechevalier, 1976). The new family encompassed mesophilic and thermophilic organisms that produced heat sensitive, motile or nonmotile spores borne singly, in pairs, or as short chains on aerial hyphae and substrate mycelia, or formed spore vesicles as in the genus *Spirillospora*. All but one of the genera had a wall chemotype III, that is, they contained *meso*-diaminopimelic acid (*meso*-A_2pm) but no other characteristic amino acids or sugars (Lechevalier and Lechevalier, 1970, 1970c). The exception, the genus *Saccharomonospora* had a wall chemotype IV, which meant that it had *meso*-A_2pm as the diamino acid of the wall peptidoglycan and a polysaccharide fraction rich in arabinose and galactose. Other wall chemotype III sporoactinomycetes subsequently thought to be related to the genus *Thermomonospora* included the genera *Actinobifida*, *Actinosynnema*, *Nocardiopsis*, *Saccharothrix*, and *Streptoalloteichus* (Goodfellow and Cross, 1984; McCarthy, 1989).

The family *Thermomonosporaceae sensu* Cross and Goodfellow 1973 was not included in the Approved Lists of Bacterial Names (Skerman et al., 1980) nor was it recognized in *Bergey's Manual of Systematic Bacteriology*, Volume 4 (Williams, 1989). Indeed, the difficulties of formally recognizing actinomycete taxa above the genus level led Goodfellow and Cross (1984) to propose "aggregate groups", the composition of which was based on the application of modern taxonomic methods, notably on chemotaxonomic and numerical taxonomic studies. One of the nine "aggregate groups", the maduromycetes, contained the genera *Actinomadura*, *Excellospora*, *Microbispora*, *Microtetraspora*, *Planobispora*, *Planomonospora*, *Spirillospora*, and *Streptosporangium*. The maduromycetes were not conceived as a natural group but were designed to provide a temporary home for organisms that had chemotaxonomic and morphological features in common (Goodfellow, 1989). In the 1st edition of *Bergey's Manual of Systematic Bacteriology*, McCarthy (1989) recognized another artificial group, "*Thermomonospora* and Related Taxa", which encompassed the genera *Actinosynnema*, *Nocardiopsis*, *Streptoalloteichus*, and *Thermomonospora*. These organisms all had a wall chemotype II but were markedly morphologically diverse.

The introduction and application of chemotaxonomic and molecular systematic procedures provided reliable data for establishing relationships between actinomycete taxa above the genus level (Embley and Stackebrandt, 1994; Stackebrandt and Woese, 1981; Stackebrandt et al., 1997; Zhang et al., 2001). It was apparent from such studies that morphological features previously weighted for the assignment of actinomycete genera to families had little predictive value (Goodfellow, 1989; Stackebrandt and Schleifer, 1984). These developments underlined the artificial nature of previously delineated suprageneric groups (Goodfellow and Cross, 1984; Williams, 1989) and provided a baseline for the circumscription of actinomycete taxa above the genus level (Stackebrandt et al., 1997). In addition, the genus *Actinomadura* was seen to encompass two groups of organisms that had little in common (Fischer et al., 1983; Fowler et al., 1985; Goodfellow et al., 1988; Poschner et al., 1985). This division was formally recognized by Kroppenstedt et al. (1990) who proposed that the genus *Actinomadura* be retained for *Actinomadura madurae* and related species and that the *Actinoma-*

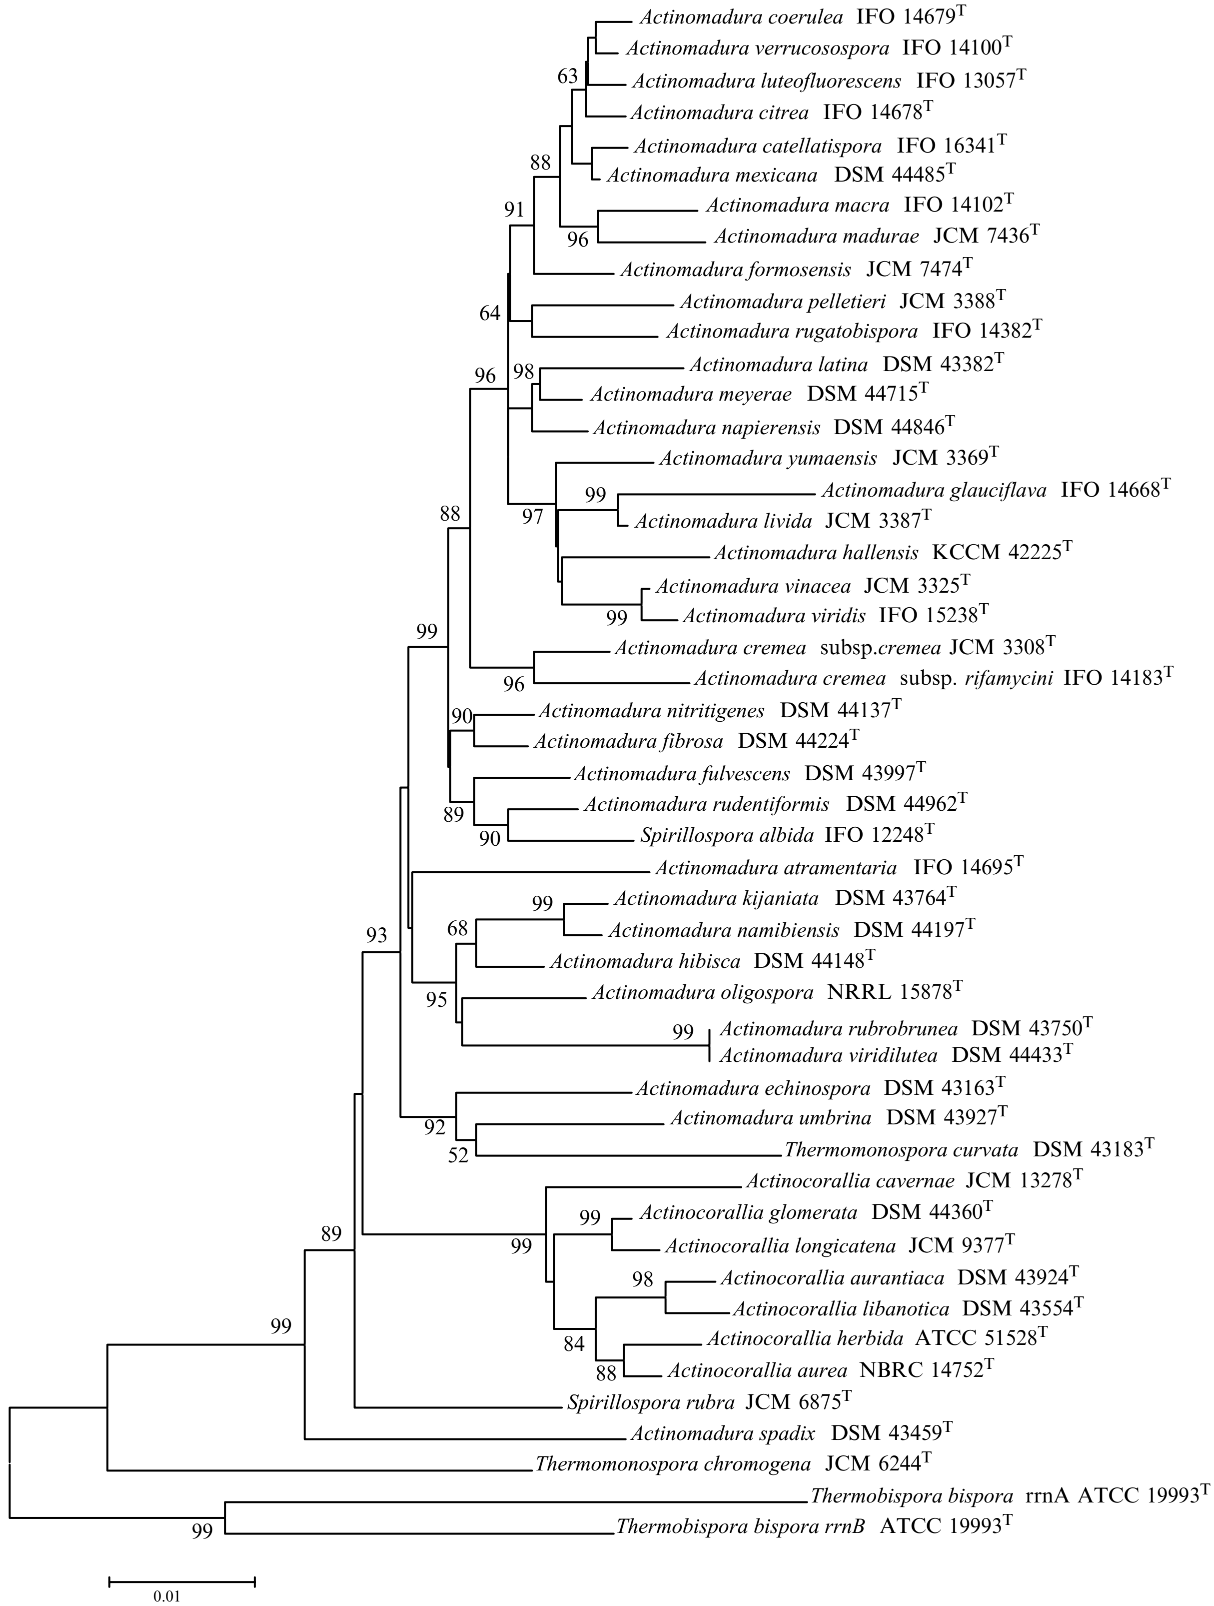

FIGURE 398. Neighbor-joining tree generated from 16S rRNA gene sequences showing relationships between taxa classified in the family *Thermomonosporaceae*. Evolutionary distances were calculated with the Jukes and Cantor method (Jukes and Cantor, 1969). Bootstrap values indicated at branching points are expressed as percentages of 1000 replications (only values greater than 40% are shown). Bar = 1 substitution per 100 nucleotides.

TABLE 298. Phenotypic characteristics separating genera classified in the family *Thermomonosporaceae*

Characteristics	*Thermomonospora*	*Actinocorallia*	*Actinomadura*	*Spirillospora*
Morphology:				
Single spores[a]	+	−	+	−
Chains of spores	+	+	+	−
Spore vesicles	−	−	−	+
Motile spores	−	−	−	+
Chemotaxonomy:				
Phospholipid type[b]	I	II	I(IV)[c]	I/II
Diagnostic sugar	None	Madurose	Madurose	Madurose
Sugar type[d]	C	B	B	B
DNA G+C content (mol%)	nd	66–73	66–73	71–73

[a]Single spores found in *Actinomadura formonsensis* and *Thermomonospora curvata*.

[b]Phospholipid types according to Lechevalier et al. (1977, 1981). Characteristic phospholipids: I, nitrogenous phospholipids absent (phosphatidylglycerol variable); II, only phosphatidylethanolamine; III, phospholipids containing glucosamine (with phosphatidylethanolamine variable) and IV, phospholipids containing glucosamine (with phosphatidylethanolamine variable).

[c]*Actinomadura kijaniata, Actinomadura namibiensis* and *Actinomadura napierensis* have a phospholipid type IV; the phospholipids of *Spirillospora albida* ATCC 14541 were found to be type II (Hasegawa et al., 1979).

[d]Whole-organism sugar patterns of actinomycetes containing *meso*-A_2pm: A, arabinose and galactose; B, madurose (3-*O*-methyl-D-galactose); C, no diagnostic sugars; D, arabinose and xylose (Lechevalier et al., 1970, 1971; Lechevalier and Lechevalier, 1970c).

dura pusilla group be transferred to the genus *Microtetraspora*. The *Actinomadura pusilla* group was subsequently given generic status as *Nonomuraea* Zhang et al. 1998, a proposition raised but never implemented by Goodfellow et al. (1988). Four members of the *Actinomadura madurae* group, *Actinomadura aurantiaca*, *Actinomadura glomerata*, *Actinomadura libanotica*, and *Actinomadura longicatena*, were subsequently transferred to the genus *Actinocorallia* by Zhang et al. (2001).

Other genera associated with the genus *Thermomonospora* were assigned to new families. The genera *Microbispora*, *Microtetraspora*, *Planobispora*, and *Streptosporangium* were classified in the family *Streptosporangiaceae* Goodfellow et al. 1990, the genera *Actinosynnema* and *Saccharothrix* in the family *Actinosynnemataceae* Labeda and Kroppenstedt 2000, and the genus *Saccharomonospora* in the family *Pseudonocardiaceae* Embley et al. 1988; the genus *Streptoalloteichus* is closely associated with the latter two families (Labeda and Kroppenstedt, 2000). The genus *Nocardiopsis* can be sharply separated from the genus *Thermomonospora* (Fowler et al., 1985; Kroppenstedt et al., 1990) and is now the type genus of the family *Nocardiopsaceae* which also includes the genera *Streptomonospora* Cui et al. 2001 and *Thermobifida* Zhang et al. 1998. The genus *Thermobifida* provided a home for three species previously classified in the genus *Thermomonospora*, namely, *Thermobifida alba*, *Thermobifida fusca*, and *Thermobifida mesouviformis*. The genus *Excellospora* Agre and Guzeva 1975 was included in the Approved Lists of Bacterial Names with *Excellospora viridilutea* as the type species (Skerman et al., 1980). Members of this taxon have been transferred to the genus *Actinomadura* (Kroppenstedt et al., 1990, 1991; Zhang et al., 2001) thereby underpinning the view that excellosporae should be seen as thermophilic actinomadurae (Meyer, 1989a). These developments leave the genera *Actinocorallia*, *Actinomadura*, *Spirillospora*, and *Thermomonospora* as members of the family *Thermomonosporaceae* Rainey et al. 1997 emend. Zhang et al. 2001 emend. Zhi et al. 2009.

Genus I. **Thermomonospora** Henssen 1957, 398[AL] emend. Zhang, Wang and Ruan 1998, 418[VP]

Martha E. Trujillo and Michael Goodfellow

Ther.mo.mo.no.spo′ra. Gr. n. *thermê* heat; Gr. adj. *monos* single, solitary; Gr. fem. n. spora seed; N.L. fem. n. *spora* a spore; N.L. fem. n. *Thermomonospora* the heat (-loving) single-spored (organism).

Aerobic, Gram-stain-positive, non-acid–alcohol-fast, chemoorganotrophic actinomycetes which form branched substrate/aerial mycelia. **Single spores with spiny surfaces are borne at the tips of short sporophores arising from the aerial mycelium**. Substrate mycelium may be yellow-orange to brown. White or light brown aerial mycelium is produced. **Temperature growth range 40–55°C**. **Cell wall contains *meso*-diaminopimelic acid but no diagnostic sugars**. Predominant menaquinones are MK-9(H_4), MK-9(H_6), and MK-9(H_8). Major phospholipids are diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannoside. **Rich in straight chain**, **iso- and anteiso- fatty acids, but lack mycolic acids. Isolated from soil, but is common in composts, manures, and overheated fodders**.

DNA G+C content (mol%): not determined for any members of the genus.

Type species: **Thermomonospora curvata** Henssen 1957, 401[VP].

Further descriptive information

Phylogeny. *Thermomonospora* species show a close phylogenetic relationship with members of the genus *Actinomadura*. Comparative 16S and 23S rRNA gene sequence analyses (Zhang et al., 1998, 2001) indicate that *Thermomonospora curvata*, the type species, *Actinomadura echinospora*, and *Actinomadura umbrina* form a moderately stable phyletic line which is separated from other *Actinomadura* species (see Figure 399). The phylogenetic position of *Thermomonospora chromogena* is not clear though it is evident that this organism is not closely related with other taxa in the family *Thermomonosporaceae* (Yap et al., 1999; Zhang et al., 1998). The uncertain phylogenetic relationship between *Thermomonospora chromogena* and related actinomycetes may be a reflection of its two distinct types of rRNA operons (Yap et al., 1999).

Cell morphology. The substrate and aerial mycelia of *Thermomonospora* strains consist of branching nonfragmenting hyphae. Single spores are borne on branched and unbranched sporophores on aerial mycelia. Spore clusters in *Thermomonospora chromogena* are formed by sequential sporulation on incurving hyphae. Spore arrangement on the aerial mycelium can be influenced by medium composition and incubation temperatures (Cross and Lacey, 1970). The spores are heat-sensitive and spore surfaces are spiny.

Nutrition and growth conditions. Members of the genus *Thermomonospora* are strictly aerobic, chemo-organotrophic micro-organisms and are moderately thermophilic as they grow well at 50°C. Some strains grow up to 60°C, but aerial mycelium production and sporulation are often poor at high temperatures. *Thermomonospora chromogena* shows little or no growth below 40°C with optimal growth and sporulation occurring on slightly alkaline nutrient media incubated under aerobic conditions. *Thermomonospora curvata* grows well and sporulates at pH 11.0. Most *Thermomonospora* strains can utilize fructose, glucose, mannose, and trehalose as sole carbon sources, but not dulcitol, inulin, raffinose, sorbitol, or sorbose. Enzymes produced by *Thermomonospora* strains include carboxymethylcellulase, catalase, β-galactosidase, and β-glucosidase; casein, gelatin, and keratin are degraded (McCarthy and Cross, 1984b; Trujillo and Goodfellow, 2003).

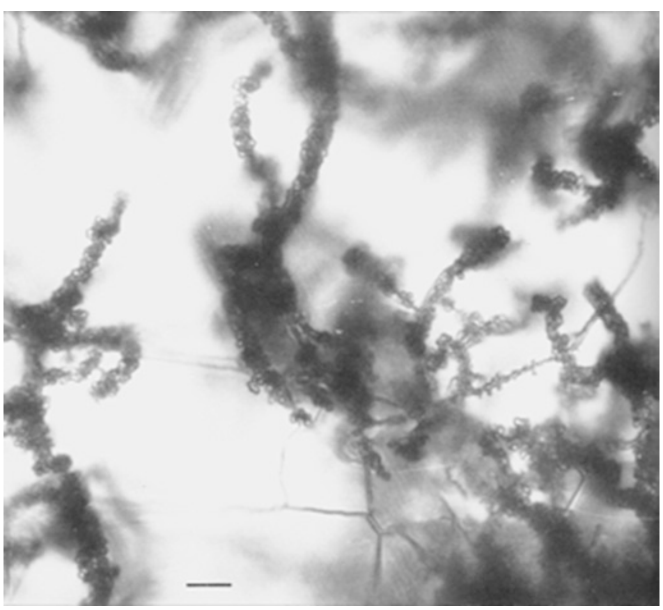

FIGURE 399. *Thermomonospora curvata.* Single spores borne laterally along aerial hyphae on branched and unbranched sporophores. Bar = 10 μm.

Genetics. Genetic studies on *Thermomonospora chromogena* ATCC 43196[T] (Yap et al., 1999) show that the genome of this strain contains six rRNA operons (*rrn*), four of which are complete and two incomplete. Comparative sequence analyses demonstrated that five of the operons had almost identical sequences whereas that of the *rrnB* operon displayed a sequence difference of 6–10%. These studies also revealed a close evolutionary relationship between the *rrnB* operon of *Thermomonospora chromogena* and the *rrnA* operon of *Thermobispora bispora*. Based on these data, Yap et al. (1999) raised the possibility that *Thermomonospora chromogena* acquired the *rrnB* operon from either *Thermobispora bispora* or from a related micro-organism via horizontal gene transfer. Plasmids have been isolated from *Thermomonospora chromogena* (McCarthy, 1989) while cellulolytic *Thermomonospora* strains can be infected by various bacteriophages (Lawrence et al., 1986).

Cell-wall composition. The cell-wall peptidoglycan of *Thermomonospora* strains contain *meso*-A_2pm, but no characteristic sugars (wall chemotype III *sensu* Lechevalier and Lechevalier, 1970b). Long-chain fatty-acid composition has been reported to be a mixture of straight-chain and branched-chain *iso*- and *anteiso*- components (Goodfellow and Cross, 1984), that is, a fatty acid pattern type 3a (Kroppenstedt, 1985). The cell wall envelope does not contain mycolic acids. The predominant menaquinones of *Thermomonospora curvata* have side chains with nine isoprene units that are hexa- or octahydrogenated whereas *Thermomonospora chromogena* contains major amounts of MK-9(H_4) (Collins et al., 1982). Thermomonosporae have a phospholipid type I pattern (Lechevalier et al., 1977, 1981), that is, one characterized by the presence of diphosphatidylglycerol, phosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannoside.

Ecology. Thermophilic thermomonosporae are found in overheated substrates such as baggasse, composts, fodders, and manures. They are especially abundant in mushroom compost (Fergus, 1964; Lacey, 1974, 1977; McCarthy and Cross, 1981, 1984b). Thermomonosporae secrete thermostable extracellular enzymes which enable them to become established as dominant populations during high temperature composting of plant residues and other wastes (Bernier and Stutzenberger, 1988; Fergus, 1964; George et al., 2001; Stutzenberger, 1971). Furthermore, *Thermomonospora* strains contribute significantly to the degradation of cellulose and lignocellulose residues from agricultural and urban wastes (McCarthy, 1987). *Thermomonospora curvata* is active in the decomposition of municipal waste compost (Stutzenberger and Sterpu, 1971, 1978). The growth of thermophilic actinomycetes in high temperature environments leads to the release of spores than can cause allergic alveolitis. At present, there are no grounds for implicating the spores of *Thermomonospora* species in such respiratory disorders (Lacey, 1988) though the cause

of mushroom worker's disease, a form of allergic alveolitis, is still a matter for conjecture.

Isolation procedures

Thermomonospora strains can be isolated from composts and overheated vegetable materials by dilution plating on nonselective media, but recovery is poor owing to the rapid growth of *Bacillus* and *Thermoactinomyces* strains. The most effective isolation methods are those based on the use of a sedimentation chamber and an Andersen air sampler (Lacey and Dutkiewicz, 1976; McCarthy and Broda, 1984; McCarthy and Cross, 1981). Dried environmental samples are shaken within the sedimentation chamber to create an aerosol of propagules which after 1–2 h of sedimentation still contain many actinomycete spores but relatively few bacteria. Actinomycetes are isolated from such spore suspensions using an Andersen sampler loaded with 1/2 strength tryptone soy agar plates supplemented with cycloheximide (50 µg/ml) to prevent the growth of fungi. *Thermomonospora* colonies can usually be recognized after incubation for 3–5 d at 50°C (Kroppenstedt and Goodfellow, 2006; McCarthy, 1989). *Thermomonospora chromogena* is readily isolated on selective media supplemented with either kanamycin (25 µg/ml; McCarthy and Cross, 1981) or rifampin (5 µg/ml; Athalye et al., 1981). Mixtures of organic matter and soil inoculated in partially sealed polyethylene bags yield samples enriched in thermophilic actinomycetes, including thermomonosporae (McCarthy, 1989).

Maintenance procedures

Thermomonospora strains can be maintained as sporulating cultures on Czapek–Dox-yeast extract-Casamino acids agar at pH 8.0, stored at 4°C, and subcultured every 4 weeks. Medium-term preservation for up to four years can be achieved by preparing spore suspensions or homogenized mycelia in 10–20% (v/v) glycerol and storing at –25°C (Zippel and Neigenfind, 1988). Lyophilization of spore and mycelia suspended in 10% skim milk provides a convenient method for long-term storage.

Differentiation of the genus *Thermomonospora* from other genera

The major characteristics that distinguish members of the genus *Thermomonospora* from other genera classified in the family *Thermomonosporaceae* are presented in Table 299, Family *Thermomonosporaceae*. Members of the redefined genus *Thermomonospora* share chemical markers in common with *Actinomadura* strains, i.e. a wall chemotype III, phospholipid type I, menaquinone type 4B2, and fatty acid type 3a (Collins et al., 1982; Kroppenstedt, 1985; Lechevalier et al., 1981, 1977, Lechevalier and H.A. Lechevalier, 1970a). The integrity of the group containing *Thermomonospora chromogena* and *Thermomonospora curvata* is also supported by fatty acid and menaquinone data. Variations in quantitative fatty acid composition and in menaquinone profiles of *Thermomonospora chromogena* and *Thermomonospora curvata* compared with other members of family *Thermomonosporaceae* may be attributed to differences in their temperature requirements for growth (Kroppenstedt et al., 1990). The lack of madurose (sugar type C; Lechevalier and Lechevalier, 1970b) might be an effect of the elevated temperature for growth. As in members of thermophilic *Actinomadura* species (formerly *Excellospora* strains) this sugar is found only in trace amounts.

TABLE 299. Characteristics differentiating between the species of the genus *Thermomonospora*[a, b]

Characteristic	*T. curvata*	*T. chromogena*
Substrate mycelium color	Yellow/orange	Brown

Taxonomic comments

The genus *Thermomonospora* was proposed by Henssen (1957) for thermophilic actinomycetes isolated from composted stable manure. Initially the taxon encompassed three species with members that produce single spores on aerial hyphae. All of these organisms formed colorless to pale yellow colonies and a white aerial mycelium, but were distinguished from one another according to aerial mycelium morphology and by the type of branching shown by substrate hyphae. *Thermomonospora curvata*, the only species isolated and maintained in pure culture, subsequently became the type species of the genus (Henssen and Schnepf, 1967). The description of the remaining two species, *Thermomonospora fusca* and *Thermomonospora lineata*, was based on morphological properties in contaminated preparations. Neither of these species were included in the Approved Lists of Bacterial Names (Skerman et al., 1980) despite the fact that *Thermomonospora fusca* had been isolated in pure culture and described in detail (Crawford, 1975; Crawford and Gonda, 1977). *Thermomonospora fusca* was subsequently validated (Moore et al., 1985) but was later transferred to the genus *Thermobifida* based on 16S rRNA gene sequencing data (Zhang et al., 1998).

A mesophilic monosporic actinomycete classified in the genus as *Thermomonospora mesophila* Nonomura and Ohara 1971a was later transferred to the genus *Microbispora* as *Microbispora mesophila* Miyadoh et al. 1990. A second mesophilic species, *Thermomonospora mesouviformis* Nonomura and Ohara 1974, was assigned to the genus *Thermobifida* as a synonym of *Thermobifida alba* Zhang et al. 1998. A third mesophilic species, *Thermomonospora formosensis*,

proposed by Hasegawa et al. (1986) was cited as a species *incertae sedis* in *Bergey's Manual of Systematic Bacteriology* (McCarthy, 1989). This species was subsequently transferred to the genus *Actinomadura* as *Actinomadura formosensis* Zhang et al. 1998.

Krasil'nikov and Agre (1964) proposed the genus *Actinobifida* for actinomycetes that formed single spores on dichotomously branched sporophores, but they failed to acknowledge that dichotomous branching had been observed previously in members of the genera *Thermomonospora* (Henssen, 1957) and *Micromonospora* (Jensen, 1930, 1932; Krasil'nikov, 1941). The following year these workers proposed a second species, *Actinobifida chromogena*, thereby implying that all actinomycetes showing dichotomous branching should be transferred to the genus *Actinobifida*. A third species, *Actinobifida alba*, was introduced by Locci et al. (1967). *Actinobifida dichotomica*, the type species of the genus was later transferred to the genus *Thermoactinomyces* as it produced endospores and *Actinobifida alba* to the genus *Thermomonospora* as it formed heat sensitive spores on substrate and aerial hyphae (Cross and Goodfellow, 1973).

A comprehensive numerical taxonomic study of the genus *Thermomonospora* and related organisms (McCarthy and Cross, 1984b, 1984a) confirmed the status of *Thermomonospora curvata* and provided strong evidence for the formal recognition of *Thermomonospora fusca*. In contrast, *Thermomonospora mesouviformis* was considered to be a synonym of *Thermomonospora alba*. These taxa, termed the "white *Thermomonospora* group" because of their white aerial mycelium, were sharply distinguished from organisms which included the type strain of *Actinobifida chromogena* (Krasil'nikov and Agre 1965; "*Thermomonospora falcata*" Henssen 1970, and similar actinomycetes isolated from mushroom compost (McCarthy and Cross, 1981). The "*chromogena*" strains with reddish-brown colonies and a light brown aerial mycelium had been provisionally assigned to the genus *Thermomonospora* Cross 1981 based on wall composition and morphological features. In the meantime, *Thermomonospora viridis* Küster and Locci 1963 had been transferred to the genus *Saccharomonospora* as *Saccharomonospora viridis* Nonomura and Ohara 1971a.

It is clear that the genus *Thermomonospora* has undergone many changes since it was proposed by Henssen (1957). The application of molecular systematic techniques has led to significant improvements in the taxonomy of this taxon, but it seems likely that in future further changes will be necessary. It also seems likely that as more data becomes available, *Thermomonospora chromogena* will be seen to merit generic status.

Differentiation of the species of the genus *Thermomonospora*

Thermomonospora curvata and *Thermomonospora chromogena* can be distinguished using a combination of phenotypic properties as shown in Table 299.

List of species of the genus *Thermomonospora*

1. **Thermomonospora curvata** Henssen 1957, 401$^{\mathrm{VP}}$

cur.va'ta. L. v. *curvo* to curve; L. part. fem. adj. *curvata* curved.

Colonies on agar media have a yellow to orange reverse color and bear an abundant white aerial mycelium. Single spores are borne laterally along aerial hyphae on branched and unbranched sporophores (Figure 399). Spores are not formed on the substrate mycelium. Grows in the range 30–53°C, but not at 60°C. Growth observed at pH 11.

Catalase, β-galactosidase and β-glucosidase are produced. Nitrate is reduced. Degrades carboxymethylcellulose, esculin, keratin, Tweens 20 and 80, and xylan, but not chitin, DNA, guanine, or pectin.

Fructose, maltose, mannose, and trehalose are used as sole carbon sources, but not L-arabinose, glycerol, *meso*-inositol, lactose, mannitol, melibiose, or L-rhamnose. Additional phenotypic characteristics are shown in Table 299.

DNA G+C content (mol%): not determined.

Type strain: ATCC 19995, CIP 105592, DSM 43183, HAMBI 1549, IFO (now NBRC) 15933, JCM 3096.

Sequence accession no. (16S rRNA gene): AF002262, D86945.

Sequence accession no. (23S rRNA gene): AF116236.

Sequence accession no. (16S–23S rRNA ITS): AF134112.

2. **Thermomonospora chromogena** (*ex* Krasil'nikov and Agre 1965) McCarthy and Cross, 1984a, 356$^{\mathrm{VP}}$ (Effective publication: McCarthy and Cross 1984b, 22.)

chro.mo.ge'na. Gr. n. *chroma* color; Gr. v. *gennaio* to produce; N.L. adj. *chromogenes* color producing.

Colonies on agar media are small, entire, raised, and dark reddish brown to light brown. Aerial mycelium white to light brownish, turning blue-gray on prolonged incubation. A dark brown soluble pigment is often produced. Spore clusters on the aerial mycelium are formed by sequential sporulation on incurving hyphae (Figure 400). Spores are not formed on the substrate mycelium. Grows in the range 40–53°C, but not at 60°C. Does not grow at pH 11.

β-Galactosidase and β-glucosidase are produced, but not catalase. Nitrate is reduced. Degrades arbutin, carboxym-

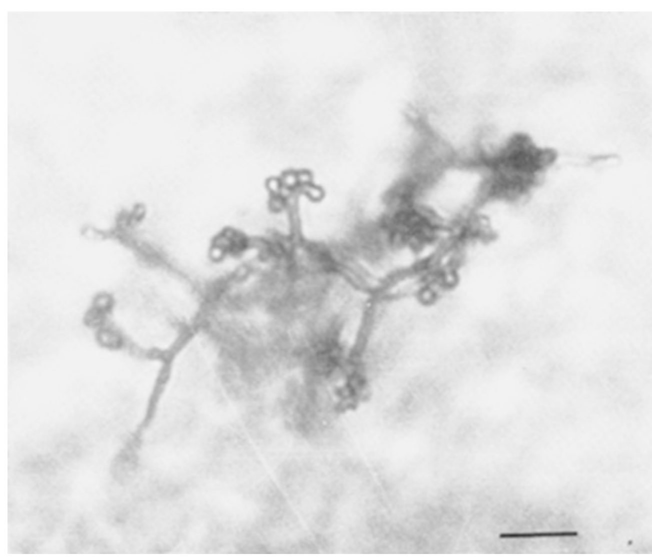

FIGURE 400. *Thermomonospora chromogena*. Single spores produced sequentially on incurving hyphae. Bar = 10 μm.

ethylcellulose, esculin, keratin, pectin, Tweens 20 and 80, tyrosine, and xylan but not chitin or DNA.

Glucose, mannose, and trehalose are used as sole carbon sources, but not L-arabinose, dulcitol, glycerol, inulin, melezitose, melibiose, sorbose, or xylose. Additional phenotypic characteristics are presented in Table 299.

DNA G+C content (mol%): not determined.

Type strain: strain Agre no. 577, ATCC 43196, DSM 43794, NBRC 16096, JCM 6244, NCIB (now NCIMB) 10212, NRRL B-16983.

Sequence accession no. (16S rRNA gene): AF116558.

Genus II. **Actinocorallia** Iinuma, Yokota, Hasegawa and Kanamuru 1994, 233^VP emend. Zhang, Kudo, Nakajima and Wang 2001, 381^VP

Martha E. Trujillo and Michael Goodfellow

Ac.ti.no.co.ral′li.a Gr. n. *actis actinos* a ray; L. n. *corallium* coral; N.L. fem. n. *Actinocorallia* (*sic*) intended to mean a microorganism (actinomycete) that forms sporophores resembling coral.

Aerobic, Gram-stain-positive, nonmotile actinomycete which forms branched non-fragmenting vegetative hyphae. **Spore chains are formed on the aerial mycelium**. Spores are cylindrical or rod-shaped. **Spore surface smooth or warty**. Substrate mycelium pale yellowish to brown. Mature aerial mycelium is pale yellow or pink. Chemo-organotrophic. Temperature growth range is 7–42°C. Melanin pigments are not produced. Does not grow in the presence of 5% (w/v) NaCl. Cell wall contains *meso*-2,6-diaminopimelic acid and *N*-acetylated muramic acid. **Major phospholipids are diphosphatidylglycerol, phosphatidylethanolamine, and phosphatidylinositol**. Predominant menaquinones are MK-9(H_4), MK-9(H_6), and MK-9(H_8). Hexadecanoic, 14-methylpentadecanoic, octadecanoic, and 19-methyloctadecanoic acids are the predominant fatty acids. Mycolic acids are absent.

DNA G+C content (mol%): 66.2–73.0 (T_m, HPLC).

Type species: **Actinocorallia herbida** Iinuma, Yokota, Hasegawa and Kanamuru 1994, 233^VP.

Further descriptive information

Phylogeny. The genus *Actinocorallia* encompasses seven species, *Actinocorallia aurantiaca*, *Actinocorallia aurea*, *Actinocorallia cavernae*, *Actinocorallia glomerata*, *Actinocorallia herbida*, *Actinocorallia libanotica*, and *Actinocorallia longicatena*, which form a distinct phyletic line in the *Thermomonosporaceae* 16S rRNA gene tree (Figure 398). Members of this taxon share 16S rRNA gene similarities within the range 97.3–99.4%. Representatives of the genus contain 16S rRNA signatures characteristic of the family *Thermomonosporaceae* (Stackebrandt et al., 1997). The type strains of *Actinocorallia glomerata* and *Actinocorallia longicatena*, the two most closely related strains in the 16S rRNA phyletic line, share DNA:DNA relatedness values of 36% and 39% in reciprocal crosses (Itoh et al., 1995). The 16S–23S internal transcribed spacer regions of representative strains share high nucleotide sequence similarities and form a well delineated taxon based on partial sequence analyses of 23S rRNA genes (Zhang et al., 2001).

Cell morphology. *Actinocorallia* strains form well developed, branched, nonfragmenting substrate hyphae, features they have in common with members of the genus *Actinomadura*. Aerial hyphae differentiate into long chains of spores after 10–14 d growth on a range of media, including glycerol-asparagine, oatmeal, tyrosine and yeast extract-malt extract agars. *Actinocorallia herbida* produces characteristic coralloid sporophores on glycerol-asparagine, humic acid-vitamins, oatmeal, and yeast extract-malt extract agars. These arise from the substrate mycelium and differentiate into long chains of non-motile spores (more than 30 spores per chain) at the tips; coremia have been observed, albeit rarely, on yeast extract-malt extract agar. The spores of *Actinocorallia aurantiaca* and *Actinocorallia libanotica* are connected by intersporal pads (Figure 401). *Actinocorallia glomerata* forms distinctive globular or amorphous spore masses (pseudosporangia-like structures), 1.5–5.0 µm in diameter, in which hyphae are coiled or intertwined (Figure 402). *Actinocorallia longicatena* is characterized by straight to flexuous chains bearing arthrospores (more than 20 spores) (Figure 403).

Nutrition and growth conditions. *Actinocorallia* strains are aerobic and chemo-organotrophic with an oxidative metabolism. They grow well on oatmeal agar and have no specific requirements for minerals or vitamins. Members of the genus

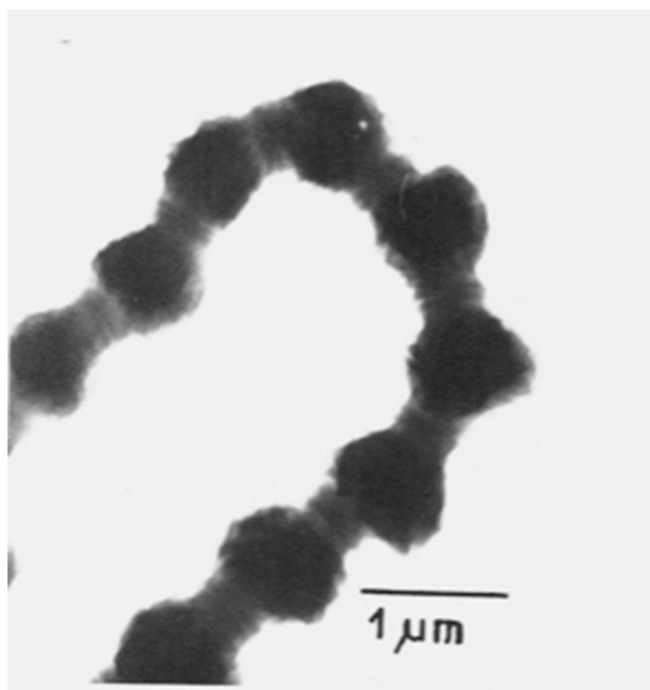

FIGURE 401. *Actinocorallia libanotica* strain IMET 9618. Spore chain with "intersporal pads". Electron micrograph (16,500×).

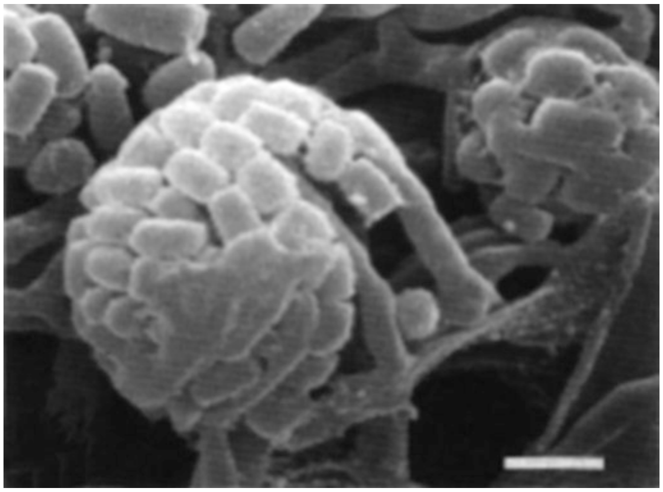

FIGURE 402. *Actinocorallia glomerata* strain I-226. Pseudosporangium-like structures. The micro-organism was incubated on oatmeal agar at 28°C for 2–3 weeks. Electron micrograph (bar = 1 µm). (Reproduced with permission from Itoh et al., 1995. Actinomycetologica *9*: 167.)

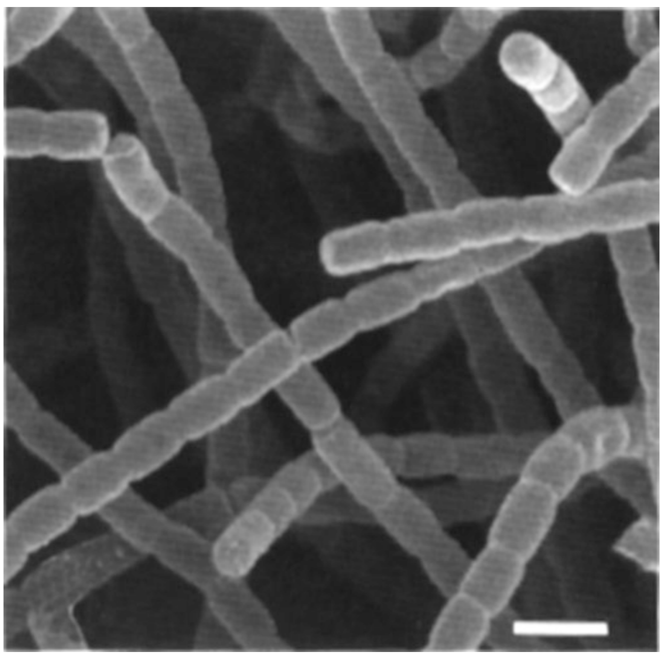

FIGURE 403. *Actinocorallia longicatena* strain I-497. Chains of arthrospores. The micro-organism was incubated on a tenth strength yeast extract-malt extract agar at 28°C for 2–3 weeks. (bar = 1 µm). (Reproduced with permission from Itoh et al., 1995. Actinomycetologica *9*: 167.)

are metabolically active (Table 300), but the descriptions of most species are based on relatively limited studies on single isolates. In contrast, *Actinocorallia aurantiaca* and *Actinocorallia libanotica* strains were included in extensive numerical taxonomic studies on *Actinomadura* and related taxa (Athalye et al., 1985; Trujillo and Goodfellow, 2003).

Cell-wall composition. *Actinocorallia* strains contain *meso*-diaminopimelic acid (*meso*-A_2pm) as the major wall diamino acid and, with the exception of *Actinocorallia cavernae*, contain madurose, that is, they have a wall chemotype III B *sensu* Lechevalier and Lechevalier (1970b). The diagnostic sugar madurose is found in other genera, including *Actinomadura*, *Dermatophilus*, *Microbispora*, *Planobispora*, *Planomonospora*, *Spirillospora*, and *Streptosporangium*. Whole-organism hydrolysates of *Actinocorallia glomerata* and *Actinocorallia longicatena* also contain galactose, glucose, mannose, and ribose (Itoh et al., 1995), and those of *Actinocorallia cavernae* contain glucose, mannose, and minor amounts of galactose (Lee, 2006).

The major phospholipids of *Actinocorallia* strains are diphosphatidylglycerol, phosphatidylethanolamine, and phosphatidylinositol, a profile which corresponds to phospholipid pattern type II *sensu* Lechevalier et al. (1981). The predominant menaquinones are MK-9(H_4) and MK-9(H_6) with smaller amounts of MK-9(H_8). *Actinocorallia aurantiaca* also contains a small proportion of MK-9(H_2) and *Actinocorallia libanotica* small amounts of MK-9(H_0) and MK-9(H_2) (Kroppenstedt et al., 1990). *Actinocorallia* strains contain complex mixtures of straight chain saturated, unsaturated, iso-branched, anteiso-branched and 10-methylated branched fatty acids, that is, a type 3a pattern *sensu* Kroppenstedt (1985); the predominant components are hexadecanoic, 14-methylpentadecanoic, octadecenoic, and 14-methyloctadecanoic acids.

Ecology. *Actinocorallia* strains are common in soil (Iinuma et al., 1994; Lavrova and Preobrazhenskaia, 1975; Lee, 2006; Meyer, 1979) where they probably play a role in the turnover of organic matter. They have also been isolated from a decayed leaf of a deciduous tree and from the root of a herbaceous plant (Itoh et al., 1995).

Isolation procedures

Actinocorallia strains can be isolated using methods described for *Actinomadura*. *Actinocorallia aurantiaca* was isolated from soil by Lavrova and Preobrazhenskaya (1975) using Gauze's medium 2 supplemented with rubromycin (0.5, 1.0, or 2.0 µg/ml), an antibiotic that inhibits the growth of common streptomycetes on isolation plates thereby allowing the development of "rare" actinomycetes. Iinuma et al. (1994) isolated *Actinocorallia herbida* by inoculating serial dilutions of soil onto colloidal chitin-vitamins agar and incubating the inoculated plates at 28°C for up to 3 weeks. *Actinocorallia glomerata* and *Actinocorallia longicatena* were isolated from plant material after washing with sterile water and drying it at 28°C for 7 d. The dried samples were blended in sterile water prior to incorporation into yeast extract agar (0.02%, w/v) supplemented with cycloheximide and nystatin (each at 50 µg/ml) and incubated at 25°C for up to 3 weeks (Itoh et al., 1995).

Maintenance procedures

Short-term storage can be achieved by serial transfer on modified Bennett's or yeast extract-malt extract agars, and long-term storage by lyophilization or storage in liquid nitrogen. For lyophilization, spores and mycelia are suspended in a suitable fluid such as 7.5% (w/v) glucose serum or 10% skimmed milk. Suspensions of spores and mycelium in glycerol (20%, v/v) can be stored in liquid nitrogen at –80°C.

Differentiation of the genus *Actinocorallia* from other genera

Actinocorallia strains can be distinguished from the other three genera classified in the family *Thermomonosporaceae* using a combination of chemotaxonomic, morphological, and

TABLE 300. Characteristics differentiating the species of the genus *Actinocorallia*[a,b]

Madurose in whole-cell sugars	+	+	+	–	+	+	+

[a]Symbols: +, positive; –, negative; nd, not determined.

[b]Data from: Athalye et al. (1985), Iinuma et al. (1994), Itoh et al. (1995), Lavrova and Preobrazhenskaya (1975), Lee (2006), Meyer (1979), Tamura et al. (2007), Trujillo and Goodfellow (2003) and Zhang et al. (2001).

phylogenetic data (Table 298). They can be separated readily from members of the genus *Actinomadura* as they have a phospholipid type I as opposed to a phospholipid type II pattern (Kroppenstedt and Goodfellow, 2006).

Taxonomic comments

The genus *Actinocorallia* Iinuma et al. 1994 was proposed to accommodate a single species, *Actinocorallia herbida*. The single representative of this taxon produced characteristic coralloid sporophores and was considered to have a wall chemotype III/C, that is, it contained *meso*-A_2pm but no diagnostic sugars. Zhang et al. (1998) found that *Actinocorallia herbida*, *Actinomadura aurantiaca*, and *Actinomadura libanotica* formed a 16S rRNA gene clade that was well separated from one that included the rest of the *Actinomadura* species; these findings raised the question whether the latter two species should be transferred to the genus *Actinocorallia*.

Following an extensive chemotaxonomic and phylogenetic study of members of the family *Thermomonosporaceae*, Zhang et al. (2001) emended the description of the genus *Actinocorallia* in order to accommodate four species previously classified in the genus *Actinomadura*. Thus, *Actinomadura aurantiaca*, *Actinomadura glomerata*, *Actinomadura libanotica*, and *Actinomadura longicatena* were transferred to the genus *Actinocorallia* as *Actinocorallia aurantiaca*, *Actinocorallia glomerata*, *Actinocorallia libanotica*, and *Actinocorallia longicatena*, respectively. Zhang and his colleagues also detected major amounts of diphosphatidylglycerol, phosphatidylethanolamine, and phosphatidylinositol in *Actinocorallia libanotica* and the presence of madurose in *Actinocorallia herbida*. These findings mean that *Actinocorallia libanotica* has a phospholipid type II, not I, as reported by Kroppenstedt et al. (1990) and that *Actinocorallia herbida* has a sugar type B, not C, as reported by Iinuma et al. (Iinuma et al., 1994). It was clear from these findings that six of the seven *Actinocorallia* species contain madurose and have a phospholipid pattern type II *sensu* Lechevalier et al. (1977, 1981). The type strain of *Actinocorallia cavernae* lacks madurose but has a phospholipid pattern type II (Lee, 2006).

Differentiation of the species of the genus *Actinocorallia*

The differential characteristics of the species of *Actinocorallia* are given in Table 300. However, identification of members of the genus is not easy as most of the phenotypic data are based on sole representatives of species and even then there are inconsistencies between data from different studies.

Acknowledgements

The authors are grateful to Dr Olga Genilloud for reading the manuscript and providing helpful comments.

List of species of the genus *Actinocorallia*

1. **Actinocorallia herbida** Iinuma, Yokota, Hasegawa and Kanamuru 1994, 233[VP]

her'bi.da. L. fem. adj. *herbida* grassy, referring to the formation of aerial mycelia like grass.

Spores borne in long straight chains or on coralloid sporophores.

Glycerol-asparagine agar: poor growth, sparse white aerial mycelium, substrate mycelium light ivory, and no diffusible pigment. Inorganic salts-starch agar: poor growth, no aerial mycelium, substrate mycelium light wheat color, and no diffusible pigment. Oatmeal agar: moderate growth, aerial mycelium light yellow, substrate mycelium yellow, and no diffusible pigment. Tyrosine agar: poor growth, no aerial mycelium, substrate mycelium light ivory color, and dusty coral-colored diffusible pigment. Yeast extract-malt extract agar: moderate growth, sparse white aerial mycelium, substrate mycelium honey gold color, and no diffusible pigment. The temperature range for growth is 12–38°C, the optimal range 24–32°C. Glucose is used as a sole carbon source, but not inositol, mannitol, or raffinose. Grows in the presence of 3% but not 5% (w/v) NaCl. Antibiotic resistance (μg/ml) is shown towards cefsulodin (100), but not against gentamicin (100), novobiocin (20), rifampin (50), streptomycin (100), or vancomycin (50). Additional phenotypic properties are shown in Table 300. The predominant fatty acids are $C_{16:0}$ (25.8%), $C_{16:1}$ (15.4%), $C_{17:1}$ (16.0%), and $C_{18:1}$ (26.5%).

Source: soil sample collected in Bangkok, Thailand.

DNA G+C content (mol%): 73.0 (HPLC) (type strain).

Type strain: AL-50780, ATCC 51528, DSM 44254, NBRC 15485, JCM 9647, NCIMB 13337, VKM Ac-1994.

Sequence accession no. (16S rRNA gene): D85473.

Sequence accession no. (23S rRNA gene): AF134086.

Sequence accession no. (16S–23S rRNA ITS): AF134109.

2. **Actinocorallia aurantiaca** (Lavrova and Preobrazhenskaia 1975) Zhang, Kudo, Nakajima and Wang 2001, 381[VP] (*Actinomadura aurantiaca* Lavrova and Preobrazhenskaya 1975, 485[AL])

au.ran.ti'a.ca. N.L. fem. adj. *aurantiaca* orange-colored, referring to the gold-colored substrate mycelium.

Spore chains (of 4–8 spores), hooked or in spirals (one turn), in small clusters emerging directly from the agar. Spore surface warty. Spores connected by intersporal pads. Inorganic salts-starch agar: moderate growth; sparsely scattered dots of sporulating hyphae; aerial mycelium whitish, substrate mycelium cream-colored to orange, and no diffusible pigment. Oatmeal agar: moderate growth; surface farinaceous, aerial mycelium cream-colored to pink; substrate mycelium yellowish white, and no diffusible pigment. Peptone-glucose medium: moderate growth; surface farinaceous, aerial mycelium cream-colored; substrate mycelium yellow to orange, and no diffusible pigment. Yeast extract-malt extract agar: poor growth; sparsely scattered dots of sporulating hyphae; aerial mycelium whitish, substrate mycelium yellow brown, and no diffusible pigment. The temperature range for growth is 10–30°C, the optimal range is 25–28°C. The pH growth range is 6.0–10.0.

Degrades arbutin, DNA, testosterone, and Tweens 20, 40, 60, and 80, but not chitin, elastin, pectin, RNA, or xylan. Galactose, glucose, rhamnose, and trehalose are used as sole carbon sources, but not lactose, mannitol, mannose, melezitose, sorbitol, or xylitol. Antibiotic resistance (µg/ml) is shown towards ampicillin (10), benzylpenicillin (25), carbenicillin (120), cephaloridine (2), cephalothin (20), cephamandole (30), lincomycin (10), oleandomycin (20), and ticarcillin (70), but not against streptomycin (2), tobramycin (0.05), or tetracycline (20). Additional phenotypic properties are shown in Table 300.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: DSM 43924, IFO (now NRBC) 15554, IMET 9577, INA 1933, JCM 8201, KCTC 9554.

Sequence accession no. (16S rRNA gene): AF134066, AJ293701.

Sequence accession no. (23S rRNA gene): AF134072.

Sequence accession no. (16S–23S rRNA ITS): AF134090.

3. **Actinocorallia aurea** Tamura, Hatano, Suzuki 2007, 2054[VP]

au're.a. L. fem. adj. *aurea* golden.

Straight to flexuous chains of aerial spores are formed on the tip of coralloid sporophores. Spores are short, non-motile rods (0.6–0.9 × 1.0–1.5 mm). Substrate mycelium is yellow on maltose-Bennett's agar, yeast extract-malt-extract agar, inorganic salts-starch agar, glycerol-asparagine agar, and peptone-yeast extract-iron agar, and grayish white on oatmeal and tyrosine agars. The aerial spore mass is yellow on yeast extract-starch agar, maltose-Bennett's agar, and on 1/4 strength oatmeal and yeast extract-malt extract agars. Optimum temperature range for growth is 20–30°C. Grows at 37°C, but not 45°C. Does not grow on 4% (w/v) NaCl. Gelatin is liquefied, starch is hydrolyzed, and nitrate is reduced. Glucose, maltose, rhamnose, and xylose are used as sole carbon sources. Additional phenotypic properties are shown in Table 300. The major fatty acids are $C_{16:0}$ (21%), $C_{18:1}$ (19%), 10-methyl $C_{18:0}$ (10%), and $C_{17:1}$ (13%).

Source: soil.

DNA G+C content (mol%): 71–73 (HPLC).

Type strain: DSM 14752, NBRC 44434.

Sequence accession no. (16S rRNA gene): AB006177.

4. **Actinocorallia cavernae** Lee 2006, 1087[AL]

ca.ver'na.e. L. gen. n. *cavernae* of a cavern, the site from which the type strain was isolated.

Aerial hyphae differentiate into straight to flexuous spores chains. Spore surface smooth. Substrate mycelium is olive black in color on yeast extract-malt extract agar, dark yellow brown on oatmeal agar, and cream on inorganic salts-starch agar. Aerial mycelium is abundant and grayish white on inorganic salts-starch and oatmeal agars, but sparse on yeast extract-malt extract agar. Diffusible pigments are not formed. Grows optimally in the temperature range 25–30°C, but not at 10° or 37°C. Grows in the pH range 5.1–10.1, but not at pH 4.1. Does not degrade DNA or elastin. Urea is hydrolyzed. H_2S is not produced. D-Arabinose, 2,3-butandiol, cellobiose, galactose, glucose, lactose, melezitose, rhamnose, and trehalose are used as sole carbon sources, but not dulcitol, *meso*-erythritol, inositol, inulin, mannitol, methyl-D-glucoside, methyl-D-mannoside, 1,2 propandiol, raffinose, sorbitol, sorbose, or xylitol. Additional phenotypic properties are shown in Table 300. The predominant fatty acids are $C_{16:0}$ (25.9%), $C_{18:1}$ (19.2), $C_{17:0}$ (11.7%), 10-methyl $C_{18:0}$ (tuberculostearic acid, 9.4%), *ai*-$C_{17:0}$ (7.4%), and $C_{18:0}$ (6.7%).

Type strain: N3-7, DSM 45040, JCM 13278, NRRL B-24429.

Sequence accession no. (16S rRNA gene): AY966427.

5. **Actinocorallia glomerata** (Itoh, Kudo, Oyaizu and Seino 1995) Zhang, Kudo, Nakajima and Wang 2001, 381[VP] (*Actinomadura glomerata* Itoh, Kudo, Oyaizu and Seino 1995, 173)

glo.me.ra'ta. L. fem. part. adj. *glomerata* (from L. v. *glomerare* to form into ball, glomerate) gathered into a mass, referring to the pseudosporangium-like structures.

Rod-shaped spores (0.6–0.8 × 0.4–0.5 µm) are formed in slimy globular, pseudosporangia-like clusters (Figure 402) or occasionally in straight chains. Spore surface smooth. Glycerol-asparagine and tyrosine agars: moderate growth; aerial mycelium white; substrate mycelium pearl-colored, and no diffusible pigment. Inorganic salts-starch agar: moderate growth; no aerial mycelium; substrate mycelium pearl-colored, and no diffusible pigment. Oatmeal agar: good growth; aerial mycelium white; substrate mycelium sand-colored, and no diffusible pigment. Yeast-extract-malt extract agar: good growth; aerial mycelium white; substrate mycelium dull gold color, and no diffusible pigment. Temperature range for growth is 7–41°C, optimal range 28–30°C. Adenine is not degraded. Galactose, glucose, rhamnose, and trehalose are used as sole carbon sources, but not dulcitol, erythritol, inositol, mannitol, raffinose, or sorbitol. Antibiotic resistance (µg/ml) is shown towards novobiocin (20), rifampin (50), streptomycin (50), and vancomycin (50). Additional phenotypic properties are shown in Table 300. Predominant fatty acids are $C_{16:0}$ (28%), $C_{18:1}$ (20%), and 10-methyl $C_{19:0}$ (15%).

Sequence accession no. (16S–23S rRNA ITS): AF134098.

6. **Actinocorallia libanotica** (Meyer 1981) Zhang, Kudo, Nakajima and Wang 2001, 381[VP] (*Actinomadura libanotica* Meyer 1981, 215[VP])

li.ba.no'ti.ca. L. n. *Libanus* Lebanon; L. fem. suff. -*tica*, suffix denoting made of or belonging to; N.L. fem. adj. *libanotica* referring to Lebanon (the country in which the soil sample was taken).

Spores chains in hooks or curled, arranged in clusters on short hyphae on the aerial mycelium, 5–12 spores per chain: spores subspherical, and spore surface folded or warty. Spores are connected by intersporal pads (Figure 401). Inorganic

salts-starch agar: moderate growth; only a flimsy cover of aerial mycelium; substrate mycelium grayish, and no diffusible pigment. Oatmeal agar: abundant growth; surface farinaceous; aerial mycelium white to pale pink; substrate mycelium yellowish brown, and no diffusible pigment. Oatmeal-nitrate agar: abundant growth; surface farinaceous; aerial mycelium white to pale pink; substrate mycelium yellowish brown, and no diffusible pigment. Peptone-glucose medium: moderate growth; surface granular; aerial mycelium white; substrate mycelium yellowish brown, and no diffusible pigment. Yeast extract-malt extract agar: abundant growth; surface farinaceous; aerial mycelium pale pink; substrate mycelium yellowish brown, and no diffusible pigment. The temperature range for growth is 10–37°C, and the optimal range is 28–30°C. Does not produce allantoinase or urease. Degrades arbutin, RNA, testosterone, Tweens 20, 40, 60, and 80 and xylan, but not chitin, elastin, guanine, pectin, or xylan. Cellobiose, dextrin, galactose, glycogen, rhamnose, and trehalose are used as sole carbon sources, but not glucosamine, lactose, mannitol, raffinose, sorbitol, or xylitol. Antibiotic resistance (μg/ml) is shown towards ampicillin (10), benzylpenicillin (10), carbenicillin (90), cephaloridine (2), demeclocycline (2), lincomycin (10), neomycin (1), oleandomycin (3), and ticarcillin (30), but not against cephalotin (20), cephamandole (20), gentamicin (4), neomycin (3), rifampin (2), streptomycin (4), tetracycline (20), tobramycin (0.05), or vancomycin (0.25). Additional phenotypic properties are shown in Table 300.

7. **Actinocorallia longicatena** (Itoh, Kudo, Oyaizu and Seino 1995) Zhang, Kudo, Nakajima and Wang 2001, 381[VP] (*Actinomadura longicatena* Itoh, Kudo, Oyaizu and Seino 1995, 175)

lon.gi.ca.te′na. L. adj. *longus* long: L. fem. n. *catena* chain; N.L. fem. n *longicatena* a long chain.

Straight to flexuous chains of 20 or more spores are borne on aerial hyphae. Spores are rod-shaped (0.6–0.9 × 0.4 × 0.5 μm). Spore surface smooth (Figure 403). Glycerol-asparagine agar: growth moderate; sparse white aerial mycelium; substrate mycelium colorless, and no diffusible pigment. Inorganic salts-starch agar: growth poor to moderate; sparse white aerial mycelium; substrate mycelium pearl, and no diffusible pigment. Oatmeal agar: growth good; sparse aerial mycelium; substrate mycelium sandy-colored, and no diffusible pigment. Tyrosine agar: growth moderate; aerial mycelium white; substrate mycelium pearl-colored, and pale brown diffusible pigment. Yeast extract-malt extract agar: good growth; aerial mycelium white; substrate mycelium oak brown, and no diffusible pigment. Temperature range for growth is 7–37°C. Adenine is not degraded. Galactose, glucose, rhamnose, and trehalose are used as sole carbon sources, but not dulcitol, erythritol, inositol, mannitol, raffinose, or sorbitol. Antibiotic resistance (μg/ml) is shown against novobiocin (20), rifampin (50), streptomycin (50), and vancomycin (50). Additional phenotypic properties are shown in Table 300. Predominant fatty acids are $C_{16:0}$ (24%), $C_{18:1}$ (16%), and 10-methyl $C_{19:0}$ (14%).

Genus III. **Actinomadura** Lechevalier and Lechevalier 1970a, 400[AL] emend. Kroppenstedt, Stackebrandt and Goodfellow 1990, 156

MARTHA E. TRUJILLO AND MICHAEL GOODFELLOW

Ac.ti.no.ma.du′ra. Gr. n. *actis actinos* a ray; N.L. n. *Madura* Madura, name of a province in India; N.L. fem. n. *Actinomadura* referring to a micro-organism first described as the causative agent of "Madura foot" disease.

Gram-stain-positive, non-acid–alcohol-fast, nonmotile actinomycetes that form an **extensively branched non-fragmenting, substrate mycelium**. **Aerial mycelium moderately developed or absent**. When present, aerial hyphae carry up to 50 arthrospores. **Aerial mycelium at maturity forms short or occasionally long chains of arthrospores**. **Spore chains straight, hooked** (**open loops**), **or irregular spirals (1–4 turns)**. **Spore surface folded, irregular, rugose, smooth, spiny, or warty**. Color of mature sporulated aerial mycelium: blue, brown, cream, gray, green, pink, red, white, or yellow. **Colonies have a leathery or cartilaginous appearance** when aerial mycelium is lacking. Aerobic, chemo-organotrophic with an oxidative type metabolism. Temperature growth range 10–60°C. **Cell wall contains *meso*-2,6-diaminopimelic acid as the major diamino acid and *N*-acetylated muramic acid**. Whole-cell hydrolysates contain galactose, glucose, madurose, mannose, and ribose. **The major phospholipids are diphosphatidylglycerol and phosphatidylinositol**. **Menaquinones are predominantly hexahydrogenated with nine isoprene units saturated at sites II, III, and VIII**. Complex fatty acid profile is rich in branched saturated and unsaturated fatty acids, including tuberculostearic acid. Mycolic acids are absent. Widely distributed in soil. Some strains are pathogenic for animals, including man.

DNA G+C content (mol%): 66–73 (T_m, HPLC).

Type species: **Actinomadura madurae** (Vincent 1894) Lechevalier and Lechevalier 1970a, 400[AL].

Further descriptive information

Phylogeny. The genus *Actinomadura* is classified in the family *Thermomonosporaceae* Rainey et al. 1997 emend. Zhang et al. 2001 emend. Zhi et al. 2009 together with the genera *Actinocorallia* Iinuma et al. 1994 emend. Zhang et al. 2001, *Spirillospora* Couch 1963 and *Thermomonospora* Henssen 1957 emend. Zhang et al. 2001. These taxa form a distinct phyletic line in the 16S rRNA gene tree (Zhang et al., 1998, 2001) and can thereby be distinguished from the other two families that comprise the order *Streptosporangiales*, namely the families *Nocardiopsaceae* and *Streptosporangiaceae* (Goodfellow and Quintana, 2006; Gyobu, 2001; Kudo, 2001). Members of the genera *Actinomadura*, *Spirillospora*, and *Thermomonospora* are phylogenetically intermixed, but can be distinguished using morphological properties (Kroppenstedt and Goodfellow, 2006; Zhang et al. 1998, 2001). The complex topology of the *Thermomonosporaceae* 16S rRNA gene tree is shown in Figure 398.

Cell morphology. *Actinomadura* strains characteristically form nonfragmenting, extensively branched, substrate mycelia and aerial hyphae which carry 1–50 arthrospores. *Actinomadura formosensis* forms single spores on both aerial and substrate mycelia (Hasegawa et al., 1986) whereas *Actinomadura echinospora* and *Actinomadura rugatobispora* usually produce two spores per chain, sometimes three, on aerial hyphae (Miyadoh et al., 1990). Longer spore chains are characteristic of most other *Actinomadura* species though spores have not been detected in *Actinomadura fibrosa* or *Actinomadura latina* strains. Spores are borne in curled, hooked, spiral, or straight chains. Spore sufaces may be folded, irregular, rugose, smooth, shiny, or warty (Table 301).

Some strains, notably those from clinical sources, lack aerial mycelium with colonies exhibiting a cartilaginous or leathery appearance. However, members of most species form a spore-bearing, powdery aerial mycelium on media such as inorganic salts-starch, oatmeal and yeast extract-malt extract agars after cultivation for 10–14 d. At maturity, aerial mycelia may be blue, cream, gray, green, pink, yellow, or white thereby differing little from streptomycetes. Superficial similarity to streptomycetes is also reinforced by the morphology of the sporophores. *Actinomadura spadix* forms pseudosporangia-like structures, i.e. tightly spiraled spore chains embedded in a dry to slimy mass thereby simulating the colonial appearance of *Streptosporangium* strains when examined microscopically at low magnification. Actinomadurae and streptomycetes can be distinguished by direct microscopic comparison of cultures. Most *Actinomadura* strains have spores noticeably larger than the diameter of their hyphae, whereas streptomycetes have spores and hyphae of similar diameter.

Cell-wall composition. The genus *Actinomadura* was defined chemically (Lechevalier and Lechevalier, 1970a) to encompass former *Nocardia* species with cell-wall type III, i.e. with *meso*-A_2pm in the peptidoglycan, but no arabinogalactan polymer, which is in contrast to *Nocardia* species. Members of some species also contain small amounts of the LL-isomer. Whole-organism hydrolysates contain galactose, glucose, mannose, ribose, and madurose (3-*O*-methyl-D-galactose; Lechevalier and Gerber, 1970), though the latter may be found in trace amounts. Madurose also occurs in other wall type III taxa, including *Actinocorallia*, *Dermatophilus*, *Microbispora*, *Nonomuraea*, *Planobispora*, *Planomonospora*, *Spirillospora*, and *Streptosporangium*. Differentiation from these genera is based on molecular and morphological characteristics.

Polar lipid and menaquinone composition. Most *Actinomadura* species, including *Actinomadura madurae*, the type species, have a phospholipid type I pattern (Lechevalier et al., 1977, 1981), which is characterized by the presence of diphosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides. In contrast, *Actinomadura kijaniata*, *Actinomadura namibiensis*, and *Actinomadura napierensis* have a phospholipid pattern type PIV, which is characterized by the presence of diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylinositol, phosphatidylinositolmannoside, phosphatidylmethylamine, and unknown glucosamine-containing phospholipids (Cook et al., 2005; Wink et al., 2003). *Actinomadura* strains can be differentiated from the genus *Actinocorallia* on the basis of polar lipid profiles. Members of the genus *Actinomadura* contain mainly MK-9(H_6) saturated at sites II, III, and VIII, small amounts of MK-9(H_4) saturated at sites II, III, and VIII, and small amounts of MK-9(H_8) (Kroppenstedt et al., 1990). Differentiation from other wall chemotype III genera, such as *Microbispora* or *Nonomuraea*, is difficult as members of these taxa have similar menaquinone profiles (Athalye et al., 1984; Kroppenstedt et al., 1990; Poschner et al., 1985).

Fatty acid profile. Actinomadurae contain complex mixtures of fatty acids with hexadecanoic (16:0), 14-methylpentadecanoic (iso-16:0), and 10-methyloctadecanoic (tuberculostearic) acids predominating, that is, they have a fatty acid type 3a (Kroppenstedt, 1985). *Actinomadura rubrobrunea*, a thermophilic organism, can be separated from mesophilic actinomadurae by differences in fatty acid composition (Agre and Guzeva, 1975). It contains relatively high proportions of iso-branched fatty acids (high melting point) and low amounts of 10-methyl branched acids (low-melting-point) in line with its thermophilic nature. Hydroxylated fatty acids have been detected in *Actinomadura atramentaria*.

Cultural characteristics. Actinomadurae are slower-growing than streptomycetes and tend to grow well on modified Bennett's (Jones, 1949) and glucose-yeast extract agars (Athalye, 1981), and on formulations that were found to be useful in the International *Streptomyces* Project (ISP; Shirling and Gottlieb, 1966). Most strains show abundant growth on oatmeal agar (ISP 3 medium) at 28–30°C, but *Actinomadura kijaniata* and *Actinomadura macra* grow better on yeast extract- malt extract agar (ISP 2 medium). *Actinomadura vinacea* grows well on glucose-peptone agar but poorly on these media. *Actinomadura spadix* requires vitamin B12 for good growth (Nonomura and Ohara, 1971d). *Actinomadura rubrobrunea* grows well on oatmeal and peptone maize agars at 50°C, and *Actinomadura yumaensis* grows poorly on media containing inorganic nitrogen sources. *Actinomadura latina*, *Actinomadura madurae*, and *Actinomadura pelletieri*, the three recognized pathogenic species, show moderate to good growth on Czapek–Dox Casamino acids (Cross and Attwell, 1974; Trujillo, 1994).

Nutrition and growth conditions. All *Actinomadura* strains are strictly aerobic and chemo-organotrophic with an oxidative metabolism. Most species grow well at 25–40°C, but *Actinomadura formosensis*, *Actinomadura rubrobrunea*, and *Actinomadura viridilutea* are thermophilic, with optimal growth temperatures

TABLE 301. Morphological characters separating *Actinomadura* species[a]

Species	Color on oatmeal agar: Aerial mycelium	Color on oatmeal agar: Substrate mycelium	Diffusible pigments	Spore chain type	Spore surface type
A. madurae	Trace, white specks	Colorless	None	Hooks to spirals	Warty
A. atramentaria	White	Colorless	Inky brown[b]	Straight	Smooth
A. catellatispora	Yellow	Light yellow	None	Straight	Smooth
A. citrea	White to blue	Lemon yellow	Yellow	Hooks or curled	Irregular or warty
A. coerulea	Pink to blue	Colorless to pale pink	None	Hooks to spirals	Warty
A. cremea subsp. *cremea*	White to yellow	Colorless	None	Hooks to spirals	Warty
A. cremea subsp. *rifamicini*	White to yellow	Colorless	None	Hooks to spirals	Warty
A. echinospora	Yellow to pink	Orange	Yellow	Paired spores	Spiny
A. fibrosa	White	Orange	Brown	No spores formed	–
A. formosensis	White	Light apricot	None	Single	Warty
A. fulvescens	White	Red-brown	Red-brown	Spirals	Smooth
A. glauciflava	Bluish green	Yellow to brown	Yellow	Hooks, spirals	Warty
A. hallensis	White	Brown	None	Hooks, spirals	Warty
A. hibisca	Light gray	Red violet	Carmine red	Straight	Smooth

A. viridis	Green	Yellow-brown to green	None	Straight	Smooth
A. yumaensis	Gray to yellow	Gray to yellow	None	Hooks	Smooth

[a]Data from Athalye et al. (1985), Lu et al. (2003), Mertz and Yao (1990), Miyadoh et al. (1985), Meyer (1989a, 1989b), Quintana et al. (2003), Wink et al. (2003), Cook et al. (2005), Lee and Jeong (2006), and Le Roes and Meyers (2007).

[b]Pigment found on tyrosine agar and yeast extract–malt extract agar.

between 45°C and 65°C. *Actinomadura* strains can metabolize a wide range of amino acids and sugars as carbon sources for growth (Table 302); proteolytic activity is shown by the capacity of most strains to hydrolyze arbutin, casein, elastin, gelatin, testosterone, and Tweens 60 and 80 (Kroppenstedt and Goodfellow, 1992; Trujillo and Goodfellow, 2003). On the other hand, xylan is not degraded (Table 303). Pectinase activity has been reported for *Actinomadura mexicana*, *Actinomadura napierensis*, and *Actinomadura verrucosospora* (Cook et al., 2005; Trujillo and Goodfellow, 2003). Pathogenic strains of *Actinomadura madurae* produce collagenolytic enzymes (Rippon, 1968). Most actinomadurae grow in the presence of NaCl 3% (w/v). *Actinomadura atramentaria* tolerates NaCl concentrations of 7% (w/v).

Pigments. *Actinomadura madurae* and *Actinomadura pelletieri* produce prodigiosin-like pigments (Gerber, 1971, 1973; Lechevalier et al., 1971) that are similar to those of *Serratia marcescens*. Members of these species isolated from patients produce prodiginines characterized by a tripyrrole skeleton and identified as cyclononylprodiginine, nonylprodiginine, and undecylprodiginine. *Actinomadura atramentaria* produces an inky brown pigment on several media, especially in submerged cultures (Miyadoh et al., 1987); under alkaline conditions the pigment is dark green-brown and is more soluble in water. In contrast, under acidic conditions, it is dark violet and more soluble in organic solvents.

Genetics. Very little is known about the genetics of *Actinomadura* strains though extensive phylogenetic studies based on the 16S, 23S rRNA, and intergenic spacer regions have been carried out (Wang et al., 1996; Zhang et al., 1998, 2001). 16S rRNA gene sequence similarity of the type strains of all 35 validly named *Actinomadura* species is in the range 93.5–99.6%, suggesting a moderate degree of heterogeneity. Members of the taxon contain the 16S rRNA nucleotide sequence signatures characteristic of members of the family *Thermomonosporaceae* (Stackebrandt et al., 1997).

[a]Symbols: +, 90% or more strains positive; −, 10% or less strains positive; d, 11–89% of strains positive; nd, not determined.

[b]Data from Athalye (1981), Athalye et al. (1985), Goodfellow et al. (1979), Horan and Brodsky (1982), Kim (1999), Labeda et al. (1985), Lipski and Altendorf (1995), Lu et al. (2003), Mertz and Yao (1986, 1990), Quintana et al. (2003), Trujillo and Goodfellow (1997a, 2003), Cook et al. (2005), Lee and Jeong (2006), Le Roes and Meyers (2007), and Wink et al. (2003).

Fischer et al. (1983) carried out extensive DNA–DNA hybridization studies on *Actinomadura* species and recorded homology values in the range 18–100%. The highest values were between *Actinomadura madurae* strains (96%) and *Actinomadura pelletieri* strains (85–100%) and between two strains of *Actinomadura verrucosospora* (96%); homology values found between strains of *Actinomadura citrea*, *Actinomadura madurae*, *Actinomadura pelletieri*, and *Actinomadura verrucosospora* ranged from 25% to 44%. In a continuation of these studies Poschner et al. (1985) found that homology values between *Actinomadura citrea*, *Actinomadura coerulea*, *Actinomadura cremea*, *Actinomadura madurae*, and *Actinomadura pelletieri* were in the range 27–48%. *Actinomadura glauciflava* shares DNA–DNA relatedness values of 53% with *Actinomadura citrea*, 62% with *Actinomadura luteofluorescens* and *Actinomadura verrucosospora*, and 38% with *Actinomadura coerulea* (Lu et al., 2003).

Recent descriptions of *Actinomadura* species where DNA–DNA hybridization studies were perfomed underline the complex genetic relationships encompassed by members of this taxon. The type strains of *Actinomadura kijaniata* and *Actinomadura namibiensis* share a DNA relatedness value of 72% but can be distinguished using phenotypic data, especially on the basis of diagnostic carbon-utilization and enzyme patterns (Wink et al., 2003). Lee and Jeong (2006) reported that *Actinomadura hallensis* contains an additional extended helix (22 nt in length) between *Escherichia coli* positions 453 and 479 with a unique nucleotide composition suggesting that sequences of this region may prove useful for species identification.

Phages. The occurrence of *Actinomadura* phages has been reported in organic mulches used to support the growth of avocado trees in Australia (Kurtböke et al., 1993).

Pathogenicity. *Actinomadura latina*, *Actinomadura madurae*, and *Actinomadura pelletieri* cause human actinomycetoma in tropical and subtropical areas, particularly on the African and American continents. The natural habitat of pathogenic actinomadurae is thought to be the environment, namely the surface layers of soil. Actinomadurae from soil invade the human body. The disease, which is often induced by implantation of organisms into tissues by sharp objects, such as thorns or soil contaminated splinters, is characterized by a progressive swelling of the infected area, distortion of the normal anatomy, and multiple draining sinuses and fistulae. Purulent discharge containing the causative agent in the form of granules is characteristic of advanced stages of the disease. Almost 80% of infections enter through the lower extremities of the body. This probably explains the etiology of "Madura foot" described by Gill of Madura in South India in 1842 (Gill, 1842). However, other sites of the human body may be affected such as the back and the head. Non-mycetomic infections caused by *Actinomadura madurae* have been reported (Wust et al., 1990), including one involving an immunocompromised patient (McNeil et al., 1992).

Pathogenic actinomadurae are thought to have a worldwide distribution, but the disease is only a major health problem in tropical and subtropical countries (Fahal, 2006). It is endemic in localities lying between latitudes 15°S and 30°N, an area which includes India, Mali, Mexico, Senegal, Somalia, Sudan, and much of Central and South America (Fahal, 2006; Fahal and Hassan, 1992). There is evidence that the distribution of the causal organisms varies. In India, *Actinomadura madurae* is the predominant causal agent (Klokke et al., 1968; Venugopal and Venugopal, 1991) whereas on the African continent the prevalent organism is *Actinomadura pelletieri* (Develoux et al., 1988; Fahal, 2006; Yu et al., 1993). Infections by *Actinomadura madurae* have been reported from temperate climatic regions, such as Greece, the Netherlands, and the USA (Davis et al., 1999; de Hoog et al., 1993; Ispoglou et al., 2003). Climatic conditions may play a major part in the distribution of the causal agents of actinomycetoma (Develoux et al., 1988; Serrano et al., 1988). The endemic regions have a rainy season of 4–6 months with a relative humidity of 60–80% and temperatures of 30–37°C followed by a dry season of 6–8 months with a relative humidity of 12–30% and daytime temperatures of 45–60°C, which fall to 15–18°C at night (Magaña, 1984).

In general, the disease is four times more frequent in males than females and mainly affects 16–40-year-old adults, but cases involving children and elderly men do occur (El Moghraby, 1971; Lopez, 1993; Serrano et al., 1986). The disease typically affects farmers and herdsmen, though people in occupational activities such as carpentry, housework, and industry can be infected. The lower and upper extremities of the body are the main sites of infection, as the skin in these areas is more likely to be exposed to soil and puncture injuries with contaminated thorns (Goodfellow, 1996; Gumaa et al., 1986; Serrano et al., 1986).

Little information is available on the pathogenicity mechanisms of *Actinomadura*. According to Pulverer and Schaal (1978) it has not been possible to demonstrate the pathogenicity of these actinomadurae for laboratory animals. However, Rippon (1968) reported that virulent strains of *Actinomadura madurae* produce a collagenase that has a significant role in the pathogenicity of the organism.

Antibiotic sensitivity. Cases of actinomycetoma caused by pathogenic actinomadurae have been treated with a range of antibiotics, including amikacin, dapsone, streptomycin, and trimethoprim-sulfamethoxazole (Welsh et al., 1987). Boiron et al. (1992) used the disk diffusion method to assess the susceptibility of *Actinomadura madurae* and *Actinomadura pelletieri* strains against 29 microbial agents and found that they were particularly sensitive to aminocycline, amikacin, imipenem, tobramycin, and vancomycin. Vera-Cabrera et al. (2004) examined 24 *Actinomadura madurae* strains isolated from patients with actinomycetoma for their sensitivity to new quinolones, including garenoxacin, gatifloxacin, moxifloxacin, and two oxazolidinones, linezolid and the compound, DA-7867, and found that all but one of the strains showed high susceptibility to all of these agents; they were most active to DA-7867 showing a minimum inhibitory concentration of 0.06 µg/ml. However, further work needs to be done to determine whether these results can be extrapolated to antibiotic activity in subcutaneous abscesses and granulomas that are formed in cases of mycetoma. Trujillo and Goodfellow (2003) found that most *Actinomadura* strains were resistant to ampicillin and rifampin, and apart from *Actinomadura oligospora* and *Actinomadura yumaensis* were susceptible to tetracycline.

Ecology. Most *Actinomadura* species have been isolated from soil where they probably have a role in organic matter turnover (Galatenko and Preobrazhenskaya, 1981; Horan and Brodsky, 1982; Labeda et al., 1985; Lavrova et al., 1972; Lee

and Jeong, 2006; Lu et al., 2003; Meyer, 1979, 1989a, 1989b; Miyadoh et al., 1987, 1989; Nonomura and Ohara, 1971c; Preobrazhenskaya et al., 1975b; Quintana et al., 2003; Wink et al., 2003). Preobrazhenskaya and her colleagues (Chormonova and Preobrazhenskaya, 1981; Galatenko et al., 1987; Galatenko and Preobrazhenskaia, 1981) studied the occurrence and frequency of *Actinomadura* species in different soils. A comparison of chernozem, dark chestnut, and sierozem soils in Kazakhstan and Turkmenistan showed that the number of *Actinomadura* strains was higher in cultivated than in uncultivated soils. The highest numbers of actinomadurae were isolated from chernozem soil (Kazakhstan) though *Actinomadura citrea* was the most prevalent species followed by *Actinomadura cremea* and *Actinomadura verrucosospora*. The dark chestnut soil (cultivated) contained approximately half the number of actinomadurae found in the chernozem soil, but the species diversity of the two soils was similar. The lowest numbers of actinomadurae were isolated from sierozem soil (Turkmenistan). The frequency of actinomadurae appears to depend upon the humus content of the soil. *Actinomadura rubrobrunea* was isolated from Egyptian soils in which maize and rice had been cultivated (Agre and Guzeva, 1975), and *Actinomadura nitritigenes* was isolated from a laboratory scale biofilter that contained tree bark compost as the packing material and which was supplied with ammonia (Lipski and Altendorf, 1995). There is evidence that clinically and ecologically significant actinomadurae are underspeciated (Trujillo and Goodfellow, 2003).

Actinomadura latina, *Actinomadura madurae*, and *Actinomadura pelletieri* strains have been isolated mainly from clinical material, though there is evidence that members of *Actinomadura madurae* are widespread in organically rich soils. *Actinomadura madurae* strains isolated from environmental samples tend to lack the red endopigment of clinical isolates and sporulate more readily (Gerber, 1971, 1973; Kroppenstedt and Goodfellow, 1992; Lechevalier et al., 1971). *Actinomadura latina* and *Actinomadura pelletieri* have only been found in clinical specimens.

Enrichment and isolation procedures

Many different media have been employed for the isolation of *Actinomadura* strains, especially from soil samples. Those that have proved to be the most effective include egg albumin (Lawson and Davey, 1972), glycerol-asparagine (ISP medium 5; Shirling and Gottlieb, 1966), oatmeal (ISP medium 3; Shirling and Gottlieb, 1966), inorganic salts-starch (ISP medium 4; Shirling and Gottlieb, 1966) and yeast extract-malt extract (ISP medium 2; Shirling and Gottlieb, 1966) agars. Strains may be isolated from agar plates after incubation for up to 6 weeks. Enrichment of actinomadurae from soil can be achieved using pretreatment regimes and selective media. Nonomura and Ohara (1971d) reduced the number of unwanted micro-organisms by air-drying soil, applying dry heat at 100°C for 1 h before plating diluted soil suspensions onto several media, notably arginine-vitamins (AV) and mineral-glucose-asparagine (MGA) agars and incubating for several weeks at 28–30°C. Isolation media should be supplemented with antifungal antibiotics such as cycloheximide to inhibit fungal growth.

Lavrova et al. (1972) and Preobrazhenskaya et al. (1975b) increased the number of actinomadurae isolated from soils by the addition of antibiotics to medium 2 of Gauze et al. (1957); these antibiotics inhibited the growth of bacteria and more frequently occurring streptomycetes thereby providing more favorable conditions for the slow-growing actinomadurae. Bruneomycin (0.5, 1.0, or 2.0 μg/ml), rubomycin (5.0, 10.0, or 20.0 μg/ml), and streptomycin (0.5, 1.0, or 2.0 μg/ml) proved to be the most effective antibiotics. Athalye et al. (1981) combined drying and heat pretreatment regimes with the use of rifampin (5 μg/ml) as the selective agent for the isolation of *Actinomadura* strains from diverse environmental samples. The mean numbers of actinomadurae recovered were higher using this treatment than obtained with untreated samples. Trujillo and Goodfellow (2003) isolated novel *Actinomadura* species from environmental samples collected from diverse geographical locations (Hong Kong, Kenya, Mexico, South Africa, and Venezuela) providing further evidence that the selective isolation procedure recommended by Athalye et al. (1981) is effective.

Pathogen *Actinomadura* species can be isolated from clinical samples, such as pus and biopsy material, using Brain Heart Infusion (Schaal, 1972), Sabouraud glucose (Gordon, 1974) and yeast extract agars (Pridham et al., 1956, 1957). All cultures should be incubated aerobically at 25–27°C and at 36°C for up to 3 weeks and examined both macroscopically and microscopically for growth every 2 d (Schaal, 1984). Actinomadurae can be recognized by their filamentous appearance, leathery colonies, and by the production of red prodiginine pigments. Actinomycetoma granules should be washed in sterile tap water before they are crushed to obtain material for inoculation of culture media.

Maintenance procedures

Heavily sporulating cultures are needed to maintain high viability irrespective of the preservation method. The highest survival rates for nonsporulating cultures are achieved using cells from the exponential growth phase. The culture age of the actinomadurae to be preserved is very important, especially for the preservation of thermophilic strains, as these lyse at the stationary phase of growth. Sporulated actinomadurae can be maintained on oatmeal agar, or other appropriate media, at 4°C and transferred every four months for short-term preservation; tubes should be sealed with silicone stoppers to prevent the agar drying out. Medium-term preservation for up to four years can be achieved by mixing spore suspensions for homogenized mycelia with glycerol (45%, v/v) and storing at –25°C (Zippel and Neigenfind, 1988). Long-term storage can be achieved by lyophilization or storage in liquid nitrogen. For lyophilization, spores and mycelia are suspended in a suitable fluid, such as 7.5% (w/v) glucose serum or 10% skimmed milk. For storage in liquid nitrogen, the micro-organisms are inoculated into small vials containing an appropriate medium, incubated until satisfactory growth is visible when the tubes are tightly sealed and placed in a liquid nitrogen container. An alternative simple and practical method involves nitrogen cryopreservation of material in small polyvinyl chloride tubes ("straws") at –196°C (Hoffmann, 1989a, 1989b).

Differentiation from closely related taxa

Differentiating characteristics of the genus *Actinomadura* and other closely related taxa are presented in Table 298, Family *Thermomonosporaceae*. The genus *Actinomadura* can be readily separated from other members of the family *Thermomonosporaceae*

and from other closely related taxa using chemotaxonomic, morphological, and 16S rRNA gene sequence data. The phospholipid pattern is an important criterion for differentiating between members of the genera *Actinomadura* and *Actinocorallia*.

Taxonomic comments

The genus *Actinomadura* was described by Lechevalier and Lechevalier (1970) to accommodate aerobic actinomycetes that had a wall chemotype III and formed a branched substrate mycelium with or without a secondary mycelium that may bear chains of arthrospores. The type species was defined as *Actinomadura madurae* (Vincent 1894) Lechevalier and Lechevalier 1970. *Actinomadura dassonvillei* (Brocq-Rousseu 1904) Lechevalier and Lechevalier 1970, and *Actinomadura pelletieri* (Laveran 1906) Lechevalier and Lechevalier 1970 were also included in the genus.

Actinomadura madurae was first described in 1894 by Vincent as *Streptothrix madurae*, based on isolates from an Algerian case of Madura foot. This combination proved to be illegitimate and Blanchard (1896) transferred the organism to the genus *Nocardia* Trevisan, hence *Nocardia madurae* (Vincent 1894) Blanchard 1896 is the oldest legitimate name of this micro-organism. The organism was subsequently assigned to many genera, including *Streptomyces* (Lacey et al., 1978). The inclusion of *Actinomadura madurae* in either *Nocardia* or *Streptomyces* became untenable when it was shown that whole-organism hydrolysates contained *meso*-A_2pm and a previously unknown sugar, madurose, later identified as 3-*O*-methyl-D-galactose (Becker et al., 1965; Lechevalier, 1968; Lechevalier and Gerber, 1970). In contrast, members of the genus *Nocardia* contained A_2pm, arabinose, and galactose, and *Streptomyces* strains the LL isomer of A_2pm. *Actinomadura dassonvillei* and *Actinomadura pelletieri* have similar taxonomic histories, although *Actinomadura pelletieri* was first placed in the genus *Micrococcus* by Laveran (1906) because the colonies fragmented into cocci suggesting a *Rhodococcus* species. *Actinomadura pelletieri* was subsequently classified in the genus *Nocardia* Pinoy 1912 then in the genus *Streptomyces* Waksman and Henrici 1948. *Actinomadura dassonvillei* was seen to differ from the other two members of the genus *Actinomadura* in its greater vigor and sporulation and lack of madurose. The genus *Nocardiopsis* was subsequently proposed to accommodate *Actinomadura dassonvillei* strains (Meyer, 1976).

Numerical phenetic (Alderson and Goodfellow, 1979; Athalye et al., 1985; Goodfellow, 1971; Goodfellow et al., 1979; Goodfellow and Pirouz, 1982), chemical (Athalye et al., 1984; Collins et al., 1977; Fischer et al., 1983; Lechevalier et al., 1977; Minnikin et al., 1977; Yamada et al., 1977), and 16S rRNA gene sequence data (Goodfellow et al., 1988; Kroppenstedt et al., 1990) confirmed the separation between the genus *Actinomadura* and the genera *Nocardia* and *Nocardiopsis*, and suggested that *Actinomadura madurae* and *Actinomadura pelletieri* were heterogeneous taxa. There was also evidence that the taxon could be separated into two aggregate taxa, the *Actinomadura madurae* and the *Actinomadura pusilla* groups.

Fischer et al. (1983) provided compelling evidence that the genus *Actinomadura* was heterogeneous when they assigned representative strains to two aggregate groups defined using chemotaxonomic and nucleic acid pairing data. rRNA partial oligonucleotide sequencing (Fowler et al., 1985; Goodfellow et al., 1988), menaquinone (Athalye et al., 1984), polar lipid (Agre et al., 1975; Lechevalier et al., 1977), numerical taxonomic (Athalye et al., 1985; Goodfellow and Pirouz, 1982), and DNA homology studies (Poschner et al., 1985) all underlined this division. *Actinomadura madurae* and related species were seen to have a closer affinity to *Thermomonospora curvata* than to *Actinomadura pusilla* and allied taxa that were found to be related to *Streptosporangium roseum* (Fowler et al., 1985).

The division of the genus *Actinomadura* into two aggregate groups was formally recognized by Kroppenstedt et al. (1990) who proposed that the genus *Actinomadura* Lechevalier and Lechevalier 1970 be retained for *Actinomadura madurae* and related species, and that the *Actinomadura pusilla* group be reclassified in the genus *Microtetraspora* Thiemann et al. 1968. This division was supported by a polyacrylamide gel electrophoresis analysis of the ribosomal protein AT-L30 which exhibits electrophoretic mobility that is specific at the genus level (Ochi et al., 1991).

By 1991, the genus *Actinomadura* contained 34 validly described species recognized primarily by chemical and morphological features (Mertz and Yao, 1990; Meyer, 1989a, 1989b; Miyadoh et al., 1987; Terekhova et al., 1987). A phylogenetic analysis based on 16S rRNA gene sequences of *Actinomadura* type strains was carried out by Wang et al. (1996) who supported Kroppenstedt et al. (1990) in classifying members of the *Actinomadura pusilla* group in the genus *Microtetraspora*. These workers also proposed the transfer of *Microbispora echinospora* and *Microbispora viridis* to the genus *Actinomadura* as *Actinomadura echinospora* and *Actinomadura rugatobispora*, respectively (Miyadoh et al., 1990). Subsequently, the genus *Nonomuraea* was proposed for membership in the *Actinomadura pusilla* group following extensive comparative 16S rRNA gene sequencing studies (Zhang et al., 1998), a proposition first raised by Goodfellow et al. (1988).

Zhang and his colleagues also demonstrated that *Thermomonospora formosensis* was related to several *Actinomadura* species on the basis of chemotaxonomic and 16S rRNA gene sequence data (Goodfellow, 1989; Kroppenstedt et al., 1990; Kroppenstedt and Goodfellow, 1992; Kudo, 1997). In a continuation of these studies, Zhang et al. (2001) proposed that *Actinomadura aurantiaca*, *Actinomadura glomerata*, *Actinomadura libanotica*, and *Actinomadura longicatena* be transferred to the new genus *Actinocorallia* as *Actinocorallia aurantiaca*, *Actinocorallia glomerata*, *Actinocorallia libanotica*, and *Actinocorallia longicatena*.

Zhang et al. (2001) considered that *Excellospora viridilutea* should be reclassified in the genus *Actinomadura* as *Actinomadura viridilutea*. They also noted that *Spirillospora albida*, the type species of the genus, was closely related to some *Actinomadura* species on the basis of 16S rRNA gene sequence data. Further studies are needed to unravel relationships between *Actinomadura* and *Spirillospora* species. In contrast, *Actinomadura echinospora* and *Actinomadura umbrina* form a clade with *Thermomonospora curvata* based on 16S and 23S rRNA gene sequence data; further comparative taxonomic investigations are needed to resolve the status of these taxa. Finally, numerical taxonomic (Athalye et al., 1985; Trujillo and Goodfellow, 2003) and 16S and 23S rRNA gene sequence data (Zhang et al., 2001) of *Actinomadura*-related actinomycetes together with phylogenetic data (Zhang et al., 2001) indicate that *Actinomadura spadix* is sharply separated from other *Actinomadura* species, a result that is supported by polyacrylamide gel electrophoresis analysis of

the ribosomal protein AT-L30 (Ochi et al., 1991). It seems likely that *Actinomadura spadix* will be found to merit recognition as a new genus.

In summary, the systematics of the genus *Actinomadura* has been markedly improved since the 2nd edition of *Bergey's Manual of Systematic Bacteriology*. The taxon currently encompasses 35 validly published species, though it seems likely that some of the present members will be reclassified in the future.

Differentiation of the species of the genus *Actinomadura*

Published descriptions of *Actinomadura* species are often incomplete since different investigators emphasize some phenotypic features and omit others. This makes identification difficult. Nevertheless, most species can be separated using a combination of morphological and physiological properties (Table 301, Table 302, and Table 303), though in most cases only the type strain has been studied. However, even when several strains have been studied (e.g. *Actinomadura madurae*, *Actinomadura pelletieri*), the results tend to be variable or inconsistent when those from the literature are compared.

Enzymic substrates based on the fluorophores 4-methylumbelliferone (4-MU) and 7-amino-methylcoumarin (7-AMC) were carried out by Trujillo and Goodfellow (2003) to differentiate *Actinomadura* species. Encouraging results were obtained for differentiating between pathogenic *Actinomadura* species (Table 304) (Goodfellow et al., 1995; Trujillo and Goodfellow, 2003). Enzymic tests were demonstrated by Wink et al. (2003) to differentiate *Actinomadura kijaniata* from *Actinomadura namibiensis*, which share a DNA homology higher than 70%.

TABLE 304. Phenotypic characters separating pathogenic *Actinomadura* species[a,b]

Characteristic	*A. latina*	*A. madurae*	*A. pelletieri*
Degradation tests:			
Arbutin	+	+	−
Esculin	+	+	−
Starch	+	−	+
Cleavage of 7-amino-4-methylcoumarin (7AMC-) substrates:			
Glutaryl-L-phenylalanine-7AMC	−	+	+
L-Pyroglutamide-7AMC	+	+	−
Cleavage of 4-methylumbelliferone (4MU-) substrates:			
4MU-*N*-acetyl-D-galactosoamide	−	d	+
4MU-α-L-arabinopyranoside	+	+	−
4MU-β-D-cellopyranoside	+	+	−
4MU-β-D-galactoside	−	+	−
4MU-β-D-glucoside	+	+	−
4MU-β-D-glucuronide	+	+	−
4MU-β-D-lactoside	−	+	−
4MU-sulfate	−	+	−
4MU-xyloside	+	+	−
Growth on sole carbon sources (1%, w/v):

Acknowledgements

The authors are particularly indebted to Dr J. Meyer as they drew upon material from the section on *Actinomadura* she wrote for the previous edition of this Manual. They also acknowledge help from Dr L.I. Evtushenko and Dr J. Euzéby for translating some material written in Russian and for revising the etymology of some names, respectively. We also thank Dr P.R. Meyers and Dr E.T. Quintana for reading the manuscript.

List of species of the genus *Actinomadura*

1. **Actinomadura madurae** (Vincent 1894) Kroppenstedt, Goodfellow and Stackebrandt, 1990, 156[AL] (*Streptothrix madurae* Vincent 1894, 132)

ma.du'ra.e. N.L. gen. n. *madurae* of Madura, name of a district in India.

Spore chains short (3–12 spores per chain), hooked or curled, in clusters directly emerging from the agar surface or borne on long aerial hyphae. Spores are elliptical to round. Spore surface warty (Figure 404). Inorganic salts-starch agar*: poor growth; surface granular; aerial mycelium absent; substrate mycelium grayish white, and no diffusible pigment. Oatmeal agar: good growth; surface leathery; aerial mycelium absent or sparse white specks; substrate mycelium colorless center, edge often red, and no diffusible pigment. Peptone-glucose medium: poor growth; surface cartilaginous; aerial mycelium absent; substrate mycelium dark pink to red, and no diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface cartilaginous; aerial mycelium absent; substrate mycelium dark pink to brownish violet, and no diffusible pigment. Growth at 10–45°C, optimally at 28–37°C. Tweens 20, 40, and 60 are degraded. Resistant to ampicillin (5 μg/ml) and carbenicillin (120 μg/ml), but susceptible to lincomycin (10 μg/ml) and tobramycin (1 μg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

Source: clinical specimens (mycetoma) and from soil.

DNA G+C content (mol%): 66.0–68.2 (T_m) (type strain, 68.2).

Type strain: ATCC 19425, CCM 136, CCUG 32944, CECT 3043, CIP 105487, DSM 43067, HAMBI 1926, IAM 14277, IFM 0585, NBRC 14623, JCM 7436, IMET 9585, IMRU 1190, KCTC 9192, NCIMB 13469, NCTC 5654, NRRL B-3843, VKM Ac-809.

*Media used are the following: glycerol-asparagine agar (ISP 5), inorganic salts-starch agar (ISP 4), oatmeal agar (ISP 3), tyrosine agar (ISP 7), and yeast extract-malt extract agar (ISP 2) (Shirling and Gottlieb, (1966)); glucose-asparagine agar (Lindenbein, 1952), inorganic salts-starch agar (Gauze 1) (Gauze et al., 1957);

Sequence accession no. (16S rRNA gene): U58527, X97889.
Sequence accession no. (23S rRNA gene): AF1162290.
Sequence accession no. (16S–23S rRNA ITS): AF134103.

2. **Actinomadura atramentaria** Miyadoh, Amano, Tohyama and Shomura 1987, 345[VP]

a.tra.men.ta′ri.a. N.L. fem. adj. *atramentaria* (from L. n. *atramentum* any black liquid, ink) inky, referring to the inky brown diffusible pigments.

Spores are borne in longitudinal pairs or in straight chains of three or rarely four spores. Chains develop into thick tufts on the aerial hyphae. Straight chains of three to five spores are occasionally observed at the tips of sporulating aerial hyphae. Spores are oval to ellipsoidal (0.6–0.8 × 0.8–1.5 µm). Spore surface smooth (Figure 405). Glycerol-asparagine agar: good growth; moderate white aerial mycelium; substrate mycelium dark brown, and pale brown diffusible pigment. Inorganic salts-starch agar: poor growth; moderate white aerial mycelium; substrate mycelium colorless, and no diffusible pigment. Oatmeal agar: poor growth; thin white aerial mycelium; substrate mycelium colorless, and no diffusible pigment. Tyrosine agar: moderate growth; moderate white aerial mycelium; substrate mycelium dark brown, and inky brown soluble pigment. Yeast extract-malt extract agar: good growth; moderate white aerial mycelium; substrate mycelium dark brown, and inky brown diffusible pigment. Growth at 15–42°C and optimally at 28–37°C. Nitrate is reduced, milk is peptonized. Grows in the presence of NaCl 7%, w/v and at pH 12. Resistant to ampicillin (5 µg/ml), carbenicillin (100 µg/ml) and ticarcillin (80 µg/ml), but susceptible to tetracycline (20 µg/ml). Additional phenotypic data are presented in Table 302 and Table 303.

DNA G+C content (mol%): 72 (T_m).
Type strain: SF2197, DSM 43919, HUT 6547, NBRC 14695, JCM 6250, KCTC 9620, NCIMB 12618.
Sequence accession no. (16S rRNA gene): U49000.
Sequence accession no. (23S rRNA gene): AF134071.
Sequence accession no. (16S–23S rRNA ITS): AF134089.

3. **Actinomadura catellatispora** Lu, Wang, Zhang, Shi, Liu, Quintana and Goodfellow 2003, 140[VP]

ca.tel.la.ti.spo′ra. L. n. *catella* small chain; Gr. n. *spora* a seed, and in biology a spore; N. L. fem. n. *catellatispora* organism forming small chains of spores.

Short straight chains of spores (0.85 µm diameter) formed on the aerial mycelium. Spore surface smooth. Light-yellow substrate mycelium and a yellow aerial mycelium formed on yeast extract-malt extract agar. Diffusible pigments are not formed. Grows at 18–35°C. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: a mud sample taken from a sewage ditch in Southern China.
DNA G+C content (mol%): 70.8 (T_m).
Type strain: 3.24, AS 4.1522, DSM 44772, NBRC 16341, JCM 10667.
Sequence accession no. (16S rRNA gene): AF154127.

4. **Actinomadura citrea** Lavrova, Preobrazhenskaya and Svesnikova 1972, 967[AL]

ci′tre.a L. fem. adj. *citrea* of or pertaining to the citrus-tree, intended to mean lemon-yellow; referring to the lemon-yellow color of the substrate mycelium.

Spore chains (3–9 spores per chain) short, hooked or curled, in sparse clusters on moderately branched aerial mycelium. Spore surface irregular or warty. Inorganic salts-starch agar: moderate growth; surface leathery; traces of yellow aerial mycelium turning blue with age; substrate mycelium yellowish brown, and diffusible pigment yellow.

Oatmeal agar: abundant growth; surface leathery; traces of yellowish aerial mycelium turning blue with age; substrate mycelium lemon yellow, and diffusible pigment yellow. Peptone-glucose medium: good growth; surface leathery; surface filmy cover of aerial mycelium consisting of sterile hyphae and coremia; substrate mycelium yellow, and no diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface leathery; filmy cover of aerial mycelium consisting of sterile hyphae; substrate mycelium yellowish brown, and no diffusible pigment. Grows at 10–37°C and optimally at 28–30°C. RNA is degraded, but not xylan. Glycogen, maltose, and trehalose are used as carbon sources. Resistant to ampicillin (5 μg/ml), rifampin (10 μg/ml), and ticarcillin (80 μg/ml). Other phenotypic characteristics are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): 67.6 (T_m).

Type strain: ATCC 27887, BCRC (formerly CCRC) 13352, DSM 43461, NBRC 14678, IMET 9573, INA 1849, JCM 3295, KCTC 9617, NRRL B-16121, VKM Ac-1119.

Sequence accession no. (16S rRNA gene): U49001, AJ420139.

Sequence accession no. (23S rRNA gene): AF116216.

Sequence accession no. (16S–23S rRNA ITS): AF134091.

5. **Actinomadura coerulea** Preobrazhenskaya, Lavrova, Ukholina and Nechaeva 1975b, 404[AL]

co.e.ru′le.a. L. fem. adj. *coerulea* azure, blue, dark blue, referring to the blue aerial mycelium.

Spore chains curled, hooked or in spirals of one turn, arranged in tufts on long aerial hyphae. Spore surface warty. Inorganic salts-starch agar (Gauze 1): poor growth; surface slightly farinaceous; aerial mycelium pale blue; substrate mycelium colorless, and no diffusible pigment. Oatmeal agar: good growth; surface slightly farinaceous; aerial mycelium pale pink turning blue at maturity; substrate mycelium colorless or pale pink, and no diffusible pigment. Oatmeal-nitrate agar: good growth; surface slightly farinaceous; aerial mycelium white; substrate mycelium white, and no diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface granular with a filmy cover of aerial mycelium consisting of sterile hyphae and coremia; substrate mycelium pale brown, and no diffusible pigment. Grows at 10–37°C and optimally at 28–30°C. RNA is degraded. Arginine and glutamine are used as sole carbon sources. Resistant to ampicillin (10 μg/ml), cephaloridine (10 μg/ml), cephalotin (35 μg/ml), cephamandole (40 μg/ml), and ticarcillin (80 μg/ml), but is susceptible to tetracycline (20 μg/ml). Other phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): 67.0 (T_m).

Type strain: ATCC 33576, DSM 43675, NBRC 14679, IMET 9580, INA 765, JCM 3320, KCTC 9337, VKM Ac-1511.

Sequence accession no. (16S rRNA gene): U49002

Sequence accession no. (23S rRNA gene): AF116217.

Sequence accession no. (16S–23S rRNA ITS): AF134092.

6. **Actinomadura cremea** Preobrazhenskaya, Lavrova, Ukholina and Nechaeva 1975b, 404[AL]

cre′me.a. N.L. fem. adj. *cremea* cream-colored (referring to the color of the aerial mycelium).

Spore chains short, in hooks or spirals of one turn, 3–8 spores per chain arranged in clusters. Spore surface warty. Inorganic salts-starch agar: poor growth; surface granular; aerial mycelium cream-colored to pale pink; substrate mycelium colorless, and no diffusible pigment. Oatmeal agar: moderate growth; surface farinaceous; aerial mycelium white to yellowish white; substrate mycelium colorless, and no diffusible pigment. Peptone-glucose medium: good growth; surface granular; aerial mycelium white to cream-colored; substrate mycelium brown, and no diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface farinaceous; aerial mycelium white; substrate mycelium light brown, and no diffusible pigment. Grows at 20–37°C. Resistant to ampicillin (15 μg/ml), carbenicillin (120 μg/ml), cephaloridine (10 μg/ml), cephalotin (35 μg/ml), cephamandole (40 μg/ml), and ticarcillin (80 μg/ml), but is susceptible to tetracycline (20 μg/ml). Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): 68.0 (T_m).

Type strain: ATCC 33577, BCRC (formerly CCRC) 13394, DSM 43676, NBRC 14182, IMET 9578, INA 292, JCM 3308, NRRL B-16605, VKM Ac-912.

Sequence accession no. (16S rRNA gene): AF134067.

Sequence accession no. (23S rRNA gene): AF134073.

Sequence accession no. (16S–23S rRNA ITS): AF134094.

Additional comments: Gauze et al. (1975) isolated a rifamycin-producing strain (INA 1349) which they described as *Actinomadura cremea* subsp. *rifamycini*. This name was subsequently attributed to Gauze et al. (1987). Euzéby and Kudo (2001) pointed out that this taxon should be attributed to Gauze et al. (1975). However, apart for the production of rifamycin, there are no characteristics that distinguish this strain from *Actinomadura cremea*. Rifamycin is also produced by some *Nocardia* and *Streptomyces* strains.

7. **Actinomadura echinospora** (Nonomura and Ohara 1971c) Miyadoh, Amano, Tohyama and Shomura 1989, 1909[VP] (Basonym: *Microbispora echinospora* Nonomura and Ohara 1971c, 891[AL].)

e.chi.no.spo′ra. L n. *echinus* sea urchin; Gr. n. *spora* a seed, and in biology a spore; N.L. fem. n. *echinospora* spiny spore.

Aerial hyphae differentiate into a non-sporogenous main axis which bears spore-bearing side branches. Spores are formed in clusters. Initially two but sometimes three spores per chain. Spore surface spiny (Figure 406). A yellowish orange to dark yellow substrate mycelium and soluble yellow or yellowish-brown pigments are formed on oatmeal agar. A yellowish pink aerial spore mass and a yellowish brown substrate mycelium are produced on inorganic salts-starch agar-V. The temperature range for optimal growth is 35–40°C; growth is very poor at 25°C. Tween 60 is degraded. Resistant to ampicillin (15 μg/ml), carbenicillin (90 μg/ml), and streptomycin (16 μg/ml), but is susceptible to ticarcillin (70 μg/ml) and tetracycline (20 μg/ml). Requires vitamin B for growth. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): 74 (T_m).

Type strain: ATCC 27300, BCRC (formerly CCRC) 12547, DSM 43163, HUT 6548, NBRC 14042, JCM 3148, KCTC 9313.

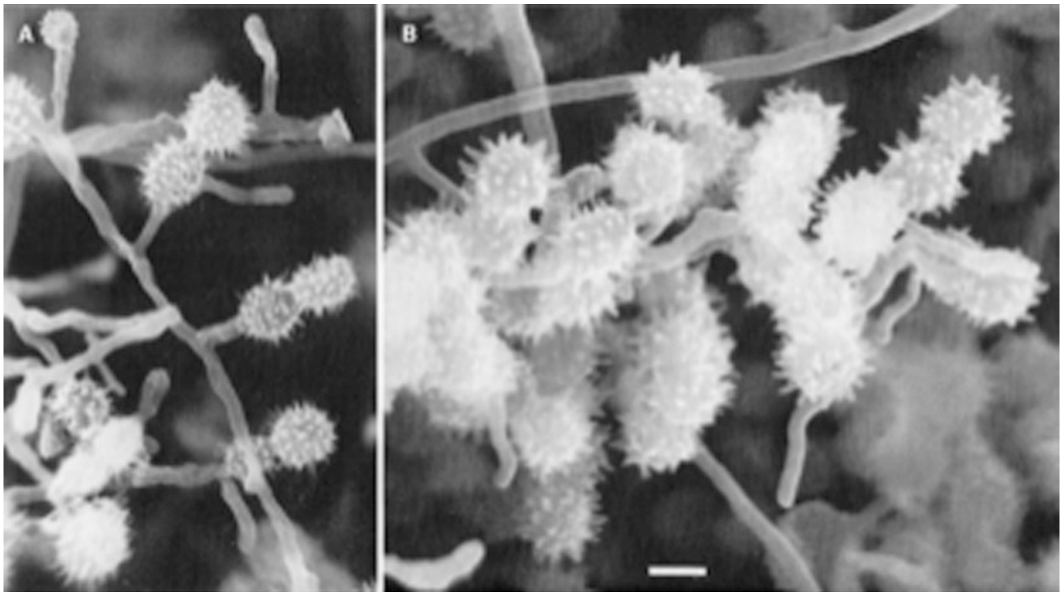

FIGURE 406. Electron micrograph of *Actinomadura echinospora* JCM 3148T. Aerial hyphae bear lateral branches where spores are produced. Spore surface is spiny. Bar = 1 μm. (Reproduced with permission from S. Amano and S. Miyadoh (A) and M. Hayakawa, H. Iino, and H. Nonomura (B). Atlas of Actinomycetes, Society for Actinomycetes Japan.)

Sequence accession no. (16S rRNA gene): U49004, AJ420135.

Sequence accession no. (23S rRNA gene): AF134075.

Sequence accession no. (16S–23S rRNA ITS): AF134095.

8. **Actinomadura fibrosa** Mertz and Yao 1990, 31VP

fi.bro′sa. L. n. *fibra* a fiber, filament; L. suff. *-osus -a -um* suffix used with the sense of full of, prone to; N.L. fem. adj. *fibrosa* fibrous, referring to the fibrous appearance of the aerial hyphae.

An extensive, reddish brown to reddish orange substrate mycelium is formed. Aerial hyphae are rarely produced except on modified Bennett's, Bennett tomato paste, oatmeal, and yeast extract-malt extract agars. When produced, the aerial mycelium is pink to white. Does not usually form soluble pigments. Grows well on modified Bennett's, glycerol-asparagine, inorganic salts-starch, tyrosine, and yeast extract-malt extract agars. Forms thick fibers. Has not been observed to produce spores. Grows at 20–45°C and optimally at 37°C. Does not degrade guanine. Produces catalase and phosphatase, and liquefies gelatin and skim milk. Acetate, formate, lactate, propionate, pyruvate, and sucrose are used as sole carbon sources. Resistant to cephalotine (30 μg/ml), lincomycin (2 μg/ml), rifampin (5 μg/ml), and lysozyme (50 μg/ml), but is susceptible to bacitracin (10 U), gentamicin (10 μg/ml), and tetracycline (30 μg/ml). Grows in the presence of NaCl (5%, w/v). Produces esterase (C_4), esterase (C_8), leucine arylamidase, naphthol-AS-BI-phosphohydrolase, β-glucosidase, and trypsin, but is negative for cystine arylmidase (API ZYM tests). Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil collected in West Africa.

DNA G+C content (mol%): not determined.

Type strain: A82810.1, ATCC 49459, DSM 44224, DSM 44224, JCM 9371, NRRL 18348.

Sequence accession no. (16S rRNA gene): AF163114, AJ293702.

Sequence accession no.(23S rRNA gene): AF163136.

Sequence accession no. (16S–23S rRNA ITS): AF163125.

9. **Actinomadura formosensis** (Hasegawa, Tanida and Ono 1986) Zhang, Wang and Ruan 1998, 418VP (*Thermonospora formosensis* Hasegawa, Tanida and Ono 1986, 22VP)

for.mo.sen′sis. N.L. fem. adj. *formosensis* of or belonging to Formosa (Republic of China).

Single spores are formed on unbranched sporophores on both aerial and substrate hyphae. The spores (diameter, about 1 μm) are heat sensitive, nonmotile, and globose. Spore surface warty. Glycerol-asparagine agar: moderate growth; aerial mycelium absent; substrate mycelium light apricot, and no diffusible pigment. Inorganic salts-starch agar: poor growth; aerial mycelium absent; substrate mycelium shell-colored, and no diffusible pigment. Oatmeal agar: poor or moderate growth; aerial mycelium poor and white when present; substrate mycelium light apricot, and no diffusible pigment. Peptone-yeast extract-iron agar: moderate growth; aerial mycelium absent; substrate mycelium cinnamon-colored, and no diffusible pigment. Tyrosine agar: moderate growth; aerial mycelium poor and white to flesh pink, and no diffusible pigment. Yeast extract-malt extract agar: aerial mycelium poor and white to flesh pink; substrate mycelium light to dusty orange, and no diffusible pigment. Growth temperature range is 23–41°C. Soluble starch and sucrose are used as sole carbon sources. Growth occurs on media supplemented with up to 2%, w/v NaCl. Susceptible to chloramphenicol, erythromycin, penicillin, tetracycline, and streptomycin. The type strain produces rifamycins O and S and is resistant to rifampin. Additional phenotypic properties are shown in Table 302 and Table 303.

Sequence accession no. (16S–23S rRNA ITS): AF134096.

10. **Actinomadura fulvescens** Terekhova, Galatenko and Preobrazhenskaya 1987, 179[VP] (Effective publication: Terekhova, Galatenko and Preobrazhenskaya 1982, 87.)

ful.ves′cens. N.L. part. adj. *fulvescens* becoming reddish-yellow.

Spore chains spiral. Spore surface smooth. Scanty white aerial mycelium, and a colorless or yellowish substrate mycelium is formed on synthetic media and a brownish-yellow substrate mycelium and soluble pigment of the same color on organic media. Grows well on modified Bennett's, Czapek's, oatmeal, and yeast extract-malt extract agars. Grows at 10–45°C. Degrades Tweens 20, 40, 60, and 80. Glutamine and histidine are used as sole carbon sources. Resistant to ampicillin (15 µg/ml), carbenicillin (100 µg/ml), cephalotin (35 µg/ml), and streptomycin (16 µg/ml), but is susceptible to tetracycline (20 µg/ml) and tobramycin (0.5 µg/ml). Additional phenotypic properties are shown in Table 302 and Table 303.

DNA G+C content (mol%): not determined.

Type strain: DSM 43923, NBRC 14347, IMET 9745, INA 3321, JCM 6833, KCTC 9339, NCTC B-16245, NRRL B-16245, VKM Ac-938.

Sequence accession no. (23S rRNA gene): AF134076.

Sequence accession no. (16S–23S rRNA ITS): AF134097.

11. **Actinomadura glauciflava** Lu, Wang, Zhang, Shi, Liu, Quintana and Goodfellow 2003, 140[VP]

glau.ci.fla′va. L adj. *glaucus* bluish-green; L. adj. *flavus* yellow; N.L. fem. adj. *glauciflava* bluish-green yellow.

Curled, hooked or spiral spore chains. Spore surface, warty. A yellow-brown, non-fragmenting substrate mycelium is produced. An abundant bluish-green aerial mycelium and a yellow diffusible pigment are formed on yeast extract-malt extract agar. Grows at 18–35°C. Casein, esculin, gelatin, hypoxanthine, and starch are degraded, but not tyrosine or xanthine. Nitrate is reduced.

Source: soil collected in Yunnan Province, China.

DNA G+C content (mol%): 72.0 (T_m).

Type strain: strain 80-60, AS 4.1202, CIP 107902, DSM 44770, DSM 44770, NBRC 14668, JCM 6161, VKM Ac-1273.

Sequence accession no. (16S rRNA gene): AF153881, AB184612.

12. **Actinomadura hallensis** Lee and Jeong 2006, 262[AL]

hal.len′sis. N.L. fem. adj. *hallensis* pertaining to Mt Halla, Jeju Island, Republic of Korea, the origin of the soil sample from which the type strain was isolated.

Short hooked or spiral spore chains. Spore surface warty (Figure 407). Substrate mycelium is grayish reddish purple on inorganic salts-starch agar, and brown on oatmeal agar and blackish purple on yeast-extract-malt extract agar. A moderate amount of white aerial mycelium is formed on inorganic salts-starch and oatmeal agars. Good growth is formed on all of these media. The temperature range for growth is 20–45°C. Produces catalase. H_2S is produced. Does not degrade Tween 80. Sucrose is used as a sole carbon soruce. Other phenotypic properties are shown in Table 302 and Table 303.

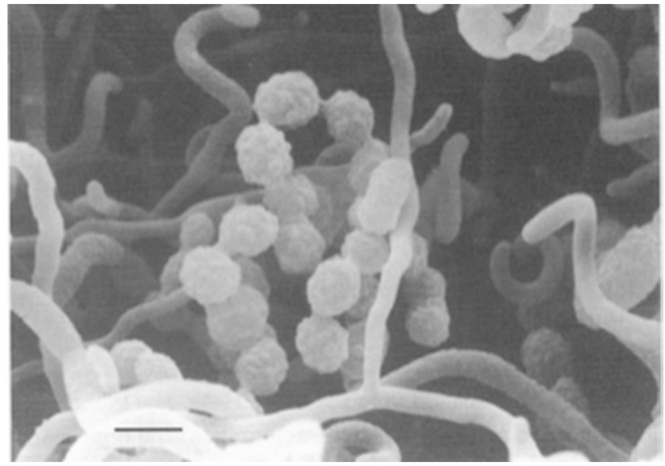

FIGURE 407. Electron micrograph of *Actinomadura hallensis* 647-1[T] grown on ISP 4 medium for 3 weeks. Bar = 0.8 µm. (Reproduced with permission from Lee and Jeong, 2006. Int. J. Syst. Evol. Microbiol. *56*: 259–264.)

Source: soil sample collected from Mt Halla, Jeju Island, Republic of Korea.

DNA G+C content (mol%): 67.5 (HPLC).

Type strain: H647-1, DSM 44987, IMSNU 50760, JCM 13882, KCCM 42245, KCTC 9992, NBRC 102110, NRRL B-24436.

Sequence accession no. (16S rRNA gene): DQ076484.

13. **Actinomadura hibisca** Tomita, Nishio, Saitoh, Yamamoto, Hoshino, Ohkuma, Konishi, Miyaki and Oki 1991, 758[AL] (Effective publication: Tomita, Nishio, Saitoh, Yamamoto, Hoshino, Ohkuma, Konishi, Miyaki and Oki 1990, 758.)

hi′bis.ca. N.L. n. *hibisca* (from Gr. n. *ibiskos* marsh mallow), rose mallow, a plant with reddish flower referring to the production of red diffusible pigments.

Long straight spore-chains (10–50 oblong spores per chain). Spore surface smooth. Coiled spore chains are occasionally formed at the tip of long chains. Pinkish white, deep red, or light brown substrate mycelium is produced on glycerol-asparagine, tyrosine and yeast-extract malt extract agars, respectively. A scant white to light pink aerial mycelium is formed on all of these media. Abundant growth is obtained on glycerol-asparagine agar, and moderate growth on glucose-asparagine and yeast extract-malt extract agars. A reddish pigment due to the production of pradimicins is produced abundantly on peptone-yeast extract-iron and yeast extract-malt extract agars. Produces melanoid pigment on tyrosine agar though growth is poor. Grows at 18–40°C. Adenine is degraded. Acid is produced from cellobiose and glucose. Produces pradimicins A, B, and C.

Enzymic activities (API ZYM system) are positive for cystine arylmidase, esterase (C_4), esterase (C_8), leucine arylamidase, naphthol-AS-BI-phosphohydrolase, β-glucosidase, and trypsin. Additional phenotypic properties are presented in Table 302 and Table 303.

DNA G+C content (mol%): not determined.

Type strain: P157-2, ATCC 53557, DSM 44148, NBRC 15177, JCM 9627, NCIMB 13253.

Sequence accession no. (16S rRNA gene): AF163115, AJ293705.

Sequence accession no. (23S rRNA gene): AF163137.

Sequence accession no. (16S–23S rRNA ITS): AF163126.

14. **Actinomadura kijaniata** Horan and Brodsky 1982, 195[VP]

ki.ja.ni′a.ta. N.L. fem. adj. *kijaniata* derived from "kijani" (the Swahili word for green).

Spore chains in long, open spirals with 10 or more spores per chain. Spores are elliptical (1.0–1.5 µm diameter by 1.5–2.0 µm long). Spore surface smooth. Inorganic salts-starch agar: moderate growth; surface flat and granular; aerial mycelium absent; substrate mycelium center slate-green and periphery light tawny, and faint green diffusible pigment. Oatmeal agar: moderate growth; surface flat to granular; aerial mycelium only white specks; substrate mycelium dark pine-green, and no diffusible pigment. Tyrosine agar: good growth; surface raised and folded; aerial mycelium abundant white; substrate mycelium lead gray, and no diffusible pigment. Yeast extract-malt extract agar: good growth; surface raised and folded; aerial mycelium only white specks; substrate mycelium center dark jade-green and periphery biscuit-colored, and no diffusible pigment. Grows at 10–60°C. RNA and Tweens 20, 40, 60, and 80 are degraded. Glutamine, glycine, histidine, leucine, methionine, phenylalanine, and valine are used as sole carbon sources. Resistant to ampicillin (15 µg/ml), cephaloridine (10 µg/ml), cephamandole (40 µg/ml), neomycin (7 µg/ml), streptomycin (16 µg/ml), rifampin (10 µg/ml), and tobramycin (5 µg/ml), but is susceptible to tetracycline (20 µg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

DNA G+C content (mol%): 69.7 (T_m).

Type strain: 13-363, ATCC 31588, CCRC 13146, DSM 43764, NBRC 14229, IMET 9741, JCM 3306, KCTC 9129, NCIMB 13755, NRRL 12069, NRRL B-16121, SCC 1256, VKM Ac-874.

Sequence accession no. (16S rRNA gene): U49006, X97890.

Sequence accession no. (23S rRNA gene): AF116219.

Sequence accession no. (16S–23S rRNA ITS): AF134099.

Additional comments: Actinomadura kijaniata differs from other *Actinomadura* species as it forms a deep green substrate mycelium and long spore chains on the aerial mycelium. Whole-cell hydrolysates contain *meso*-A_2pm together with a trace of the L-isomer (Horan and Brodsky, 1982). Furthermore, this species produces a complex of acid enol antibiotics, the major component of which was designated kijanimicin. This antibiotic has an unusual *in vitro* spectrum of activity against Gram-stain-positive and anaerobic microorganisms. *In vivo* activity has been shown against *Plasmodium berghei* and *Plasmodium chabaudi* in mice (Waitz et al., 1981).

15. **Actinomadura latina** Trujillo and Goodfellow 1997b, 917[VP] (Effective publication: Trujillo and Goodfellow 1997a, 230.)

la.ti′na. L. fem. adj. *latina* latin; named after *America Latina*, since many clinically significant strains of actinomadurae have been isolated in Latin America.

Moderate growth on Czapek, oatmeal and yeast extract-malt extract agars. Colonies cream to pink, convex, and wrinkled. Aerial mycelium absent or rare. No diffusible pigments. Grows at 10–37°C. Degrades Tweens 20, 40, and 60. Phenylalanine is used as a sole carbon sources. Resistant to rifampin (6 µg/ml), but is susceptible to ticarcillin (70 µg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

Source: a patient with actinomycetoma in the arm.

DNA G+C content (mol%): 67 (T_m).

Type strain: A10, ATCC BAA-277, DSM 43382, IFM 0961, JCM 10674.

Sequence accession no. (16S rRNA gene): AY035998.

16. **Actinomadura livida** Lavrova and Preobrazheskaya 1975, 483[AL]

li′vi.da. L. fem. adj. *livida* livid (referring to the grayish-violet color of the substrate mycelium).

Spore chains in hooks or spirals of one turn. Spore surface irregular. Inorganic salts-starch agar: good growth; surface cartilaginous glistening; aerial mycelium only microscopically visible hyphae; substrate mycelium yellowish brownish, and pale violet diffusible pigment. Oatmeal agar: good growth; surface cartilaginous dull; aerial mycelium microscopically visible hyphae; substrate mycelium pale grayish pink, and pale violet diffusible pigment. Peptone-glucose medium: good growth; surface cartilaginous; aerial mycelium absent; substrate mycelium yellowish brown, and no diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface cartilaginous; aerial mycelium absent; substrate mycelium pale brownish, and no diffusible pigment. Grows at 20–45°C. Histidine and phenylalanine are used as sole carbon sources. Resistant to cephaloridine (10 µg/ml), lincomycin (25 µg/ml), oleandomycin (20 µg/ml), rifampin (10 µg/ml), and ticarcillin (80 µg/ml), but is sensitive to ampicillin (5 µg/ml), benzylpenicillin (25 µg/ml), and tetracycline (20 µg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: ATCC 33578, DSM 43677, NBRC 14682, IMET 9575, INA 1678, JCM 3387, VKM Ac-908.

Sequence accession no. (16S rRNA gene): AF163116, AJ293706.

Sequence accession no. (16S–23S rRNA ITS): AF163127.

17. **Actinomadura luteofluorescens** (Shinobu 1962) Preobrazhenskaya and Lavrova in Preobrazhenskaya, Lavrova and Blinov 1975a, 526[AL] (*Streptomyces luteofluorescens* Shinobu 1962, 115)

lu.te.o. flu.o.res′cens. L. adj. *luteus* yellow; N.L. part. adj. *fluorescens* fluorescing; N.L. part. adj. *luteofluorescens* yellow and

fluorescing, referring to the greenish tinge of the diffusible pigment produced by the organism.

Short spore chains in hooks or curled, arranged in clusters. Spore surface warty. Inorganic salts-starch agar: poor growth; surface leathery; aerial mycelium microscopically visible hyphae; substrate mycelium orange to brown, and yellow diffusible pigment. Oatmeal agar: good growth; surface farinaceous; aerial mycelium yellowish pink turning blue with age; substrate mycelium pale greenish yellow, and greenish yellow diffusible pigment. Peptone-glucose medium: good growth; surface wrinkled leathery; aerial mycelium absent; substrate mycelium orange to brown, and yellow diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface farinaceous; aerial mycelium yellowish white; substrate mycelium dark yellow, and pale yellow diffusible pigment. Grows at 10–45°C. RNA is degraded. Resistant to ampicillin (15 μg/ml), carbenicillin (120 μg/ml), cephaloridine (10 μg/ml), cephalotin (35 μg/ml), cephamandole (40 μg/ml), rifampin (10 μg/ml), and streptomycin (16 μg/ml), but is susceptible to tetracycline (20 μg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

DNA G+C content (mol%): not determined.

Type strain: ATCC 25469, CBS 702.69, CGMCC AS 4.1382, CIP 105484, DSM 40398, NBRC 13057, ISP 5398, JCM 4203, JCM 4491, KCC S-0203, KCC S-0491, NRRL B-12327, RIA 1249, VKM Ac-1509.

Sequence accession no. (16S rRNA gene): U49008.

Sequence accession no. (23S rRNA gene): AF134079.

Sequence accession no. (16S–23S rRNA ITS): AF134101.

18. **Actinomadura macra** Huang 1980, 565[VP]

ma′cra. L. fem. adj. *macra* lean (referring to the poor, thin growth of this organism).

Sporulation is extremely rare and delayed. A few short spore chains (flexuous, hooked, or straight; 4–15 spores) have been observed after 5 weeks of incubation on isolation agar (Jensen, 1930) and Czapek sucrose agar. Spores oval to elliptical (0.8–1.0 × 1.2–2.0 μm). Spore surface smooth. Czapek sucrose-nitrate agar: poor growth; surface smooth; aerial mycelium scant and pale cream-colored; substrate mycelium colorless, and no diffusible pigment. Inorganic salts-starch agar: very scanty growth; surface smooth; aerial mycelium absent; substrate mycelium colorless or pale grayish, and no diffusible pigment. Oatmeal agar: moderate growth; surface smooth; aerial mycelium scant and cream to faint pink; substrate mycelium cream to faint pink, and no diffusible pigment. Yeast extract-malt extract agar: good growth; surface raised and wrinkled; aerial mycelium white to grayish; substrate mycelium black, and brown diffusible pigment. Grows at 10–45°C. Tweens 20, 40, 60, and 80 are degraded. Lactose, phenylalanine, and valine are used as sole carbon sources. Resistant to ampicillin (15 μg/ml), cephalotin (30 μg/ml), and carbenicillin (100 μg/ml), but is susceptible to benzylpenicillin (25 μg/ml), ticarcillin (70 μg/ml), rifampin (2 μg/ml), and tetracycline (20 μg/ml).

19. **Actinomadura mexicana** Quintana, Trujillo and Goodfellow 2004, 307[VP] (Effective publication: Quintana, Trujillo and Goodfellow 2003, 514.)

me.xi.ca′na. N.L. fem. adj. *mexicana*, referring to Mexico, the country of origin of the soil sample from which the organism was isolated.

Aerial hyphae are rare but when present may differentiate into hooked chains of spores (1 μm). Spore surface warty. Extensively branched non-fragmenting, light yellow substrate mycelium and yellow diffusible pigment formed on yeast extract-malt extract agar. Pink to palid red, convex colonies with a wrinkled morphology formed on modified Bennett's agar. Grows at 10–37°C. L-Glutamine is used as sole carbon sources. Resistant to ampicillin (15 μg/ml), benzylpenicillin (25 μg/ml), and lincomycin (25 μg/ml), but is susceptible to neomycin (1 μg/ml), streptomycin (2 μg/ml), cephalotine (20 μg/ml), and tetracycline (20 μg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

Source: soil collected in Mexico.

DNA G+C content (mol%): not determined.

Type strain: A290, DSM 44485, JCM 13236, NRRL B-24203.

Sequence accession no. (16S rRNA gene): AF277195.

20. **Actinomadura meyerae** Quintana, Trujillo and Goodfellow 2004, 307[VP] (Effective publication: Quintana, Trujillo and Goodfellow 2003, 515.)

me.ye′ra.e. N.L. gen. fem. n. *meyerae* of Meyer, named after the German microbiologist Jutta Meyer in recognition of her contributions to actinomycete systematics.

Aerial hyphae are rare but when present may differentiate into hooks and spiral chains of spores. Spore surface warty. Cream to light yellow, convex colonies with a wrinkled morphology formed on modified Bennett's agar, and a light yellow substrate mycelium on yeast extract-malt extract agar. Diffusible pigments not produced. Grows at 25–45°C and pH 7–9. RNA is degraded, but not pectin. Arginine is used as a carbon source. Resistant to ampicillin (15 μg/ml), benzylpenicillin (25 μg/ml), lincomycin (25 μg/ml), and oleandomycin (20 μg/ml), but is susceptible to rifampin (2 μg/ml) and tetracycline (20 μg/ml). Additional phenotypic data are shown in Table 302 and Table 303.

Source: garden soil collected in Mexico.

DNA G+C content (mol%): not determined.

Type strain: A288, DSM 44715, JCM 13237, NRRL B-24247.

Sequence accession no. (16S rRNA gene): AY273787.

21. **Actinomadura namibiensis** Wink, Kroppenstedt, Seibert and Stackebrandt 2003, 723[VP]

na.mi.bi.en′sis. N.L. fem. adj. *namibiensis* of or belonging to Namibia from where the type strain was isolated.

Spiral spore chains of about 20 spores are formed after about 20 d. Spore surface smooth. Substrate mycelium is salmon pink on glycerol-asparagine, inorganic salts-starch, oatmeal, tyrosine, and yeast extract-malt extract agars and colorless on peptone-yeast extract-iron agar. Soluble pigments are not produced on any of these media. White aerial hyphae are formed on glycerol-asparagine inorganic salts-starch and tyrosine agars. Enzymic activities (API ZYM system) are shown for cystine arylmidase, leucine arylamidase, naphthol-AS-BI-phosphohydrolase, β-glucosidase, and trypsin, but not for esterases (C_4) and (C_8). Other phenotypic properties are shown in Table 302 and Table 303.

Source: soil sample collected in Namibia.

DNA G+C content (mol%): not determined.

Type strain: HAG 010767, CIP 108365, DSM 44197, FH-A 1198, JCM 13238, NRRL B-24153.

Sequence accession no. (16S rRNA gene): AJ420134.

22. **Actinomadura napierensis** Cook, le Roes and Meyers 2005, 705[VP]

na.pi.e.ren′sis. N.L. fem. adj. *napierensis* of or belonging to Napier in South Africa, the source of the type strain.

Spiral spore chains are formed. Spore surfaces smooth. Grey aerial and brown-gray substrate mycelia formed on Czapek, Middlebrook 7H9, and yeast extract-malt extract agars. White aerial and substrate mycelia produced on inorganic salts-starch agar. A faint blue diffusible pigment is produced on tyrosine agar. Tween 80 is degraded, but not allantoin, guanine, hippurate, or xylan. Shows a weak H_2S reaction. Dextrin is used as a sole carbon source. Grows in the presence of 2% but not 5% (w/v) NaCl.

Source: soil in Napier, Western State Province, South Africa.

DNA G+C content (mol%): 70 (T_m).

Type strain: B60, DSM 44846, JCM 13850, NRRL B-24319.

Sequence accession no. (16S rRNA gene): AY568292.

23. **Actinomadura nitritigenes** Lipski and Altendorf 1995, 722[VP]

ni.tri.ti′ge.nes. N.L. n. *nitris -itis* nitrite; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce) producing; N.L. adj. *nitritigenes* nitrite producing.

Oval to ellipsoidal spores produced in straight or hook-like chains that are up to seven spores long. Spore surface smooth. Substrate mycelium is colorless to brown on glycerol-asparagine, inorganic salts-starch, oatmeal, peptone-yeast extract-iron, tyrosine, and yeast extract-malt extract agars. Good growth is obtained on all these media except for peptone-yeast extract-iron agar. Diffusible pigments are not produced. Aerial mycelium is either white or brown. Grows at 45°C. Tweens 20 and 80 are degraded, but not adenine, guanine, or xylan. H_2S is not produced. Starch and sucrose are used as sole carbon sources, but not alanine, propionate, pyruvate, or serine. Resistant to neomycin (3 μg/ml), but is susceptible to gentamicin (4 μg/ml) and streptomycin (4 μg/ml). Enzymic activity (API ZYM system) shown for cystine arylmidase, esterase (C_8), β-glucosidase, leucine arylamidase, naphthol-AS-BI-phosphohydrolase, and trypsin, but not for esterase (C_4). Other phenotypic properties are shown in Table 302 and Table 303.

Source: experimental biofilters filled with tree bark compost.

DNA G+C content (mol%): 74 (HPLC).

Type strain: L46, DSM 44137, NBRC 15918, JCM 10104, NCIMB 13456.

Sequence accession no. (16S rRNA gene): AY035999.

24. **Actinomadura oligospora** Mertz and Yao 1986, 180[VP]

o.li.go.spo′ra. Gr. adj. *oligos* few; Gr. n. *spora* seed; N.L. n. *oligospora* organism forming few spores, referring to the relative absence of sporophores in this organism.

Aerial mycelia are absent except for trace amounts produced on inorganic salts-starch and sodium butyrate agars. Substrate mycelia give rise to occasional sparse twisted oyster white aerial hyphae that differentiate into flexuous or hooked chains of 10–50 spores. Spores are oblong (0.5–0.7 × 0.9–1.3 μm). Spore surface smooth. Colonies grow slowly (10–20 d) and are convex with filamentous margins. Growth is best on complex media. Colony surfaces and reverse surfaces are yellowish gray to brown. Soluble pigments are produced on inorganic salts-starch and yeast-glucose agars. Grows at 20–37°C. Does not degrade adenine, calcium malate, guanine, hippurate, or keratin. Leucine is used as a sole carbon source, but not dextran or inulin. Resistant to bacitracin (10 U), cephaloridine (10 μg/ml), cephalotin (35 μg/ml), cephamandole (40 μg/ml), rifampin (10 μg/ml), and tetracycline (20 μg/ml), but is susceptible to gentamicin (10 μg/ml), streptomycin (10 μg/ml), tobramycin (10 μg/ml), and vancomycin (30 μg/ml). Produces a polyether antibiotic. Does not grow at pH 8. Additional phenotypic data are shown in Table 302 and Table 303.

Source: soil collected in Karnataka, India.

DNA G+C content (mol%): not determined.

Type strain: A80190.1, ATCC 43269, JCM 10648, NRRL 15878.

Sequence accession no. (16S rRNA gene): AF163118

Sequence accession no. (23S rRNA gene): AF163140.

Sequence accession no. (16S–23S rRNA ITS): AF163129.

25. **Actinomadura pelletieri** (Laveran 1906) Lechevalier and Lechevalier 1970a, 400[AL] (*Micrococcus pelletieri* Laveran 1906, 341)

pel.le.ti′e.ri. N.L. gen. masc. n. *pelletieri* of Pelletier, named after T. Pelletier, who first isolated this species.

Spore chains short (2–6 spores per chain), hooked or in spirals of two to three turns. Spores subspherical. Spore surface warty. Oatmeal agar: moderate growth; surface cartilaginous; aerial mycelium absent; substrate mycelium pink to brownish red, and no diffusible pigment. Oatmeal-nitrate agar: moderate growth; surface cartilaginous; traces of sporulating hyphae on aerial mycelium; substrate mycelium colorless, and no diffusible pigment. Peptone-glucose medium: moderate growth; surface cartilaginous; aerial mycelium absent; substrate mycelium brownish red, and no diffusible pigment. Yeast extract-malt extract agar: moderate growth; surface cartilaginous; traces of sterile hyphae on aerial mycelium; substrate mycelium pink to brownish red, and no diffusible pigment. Grows at 25–37°C. Tweens 20, 40, and 60 are degraded, but not adenine. Starch hydrolysis is variable. Collagenase is produced and nitrate reduced.

Cellobiose, glucose, and glycogen are used as sole carbon sources, but not adonitol, arabinose, erythritol, inositol, raffinose, or sorbitol. Does not grow in the presence of 4%, w/v, NaCl. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: actinomycetoma of the arm. Most strains classified as *Actinomadura pelletieri* have been isolated from clinical samples.

DNA G+C content (mol%): 65.5–67.3 (T_m).

Type strain: ATCC 33385, CCUG 38891, CIP 105483, DSM 43383, HUT 6549, IAM 12634, IMET 9693, JCM 3388, KCTC 9110, NBRC 103052, NCTC 4162, NRRL B-3997.

Sequence accession no. (16S rRNA gene): AF163119, AJ293710.

Sequence accession no. (23S rRNA gene): AF163141.

Sequence accession no. (16S–23S rRNA ITS): AF163130.

Additional comments: Cummins (1962), who was the first to isolate *meso*-A_2pm from whole-organism hydrolysates of members of this species, also found a small amount of L-isomer and glycine in some strains.

26. **Actinomadura rubrobrunea** (*ex* Krasil'nikov, Agre and El-Registan 1968) Kroppenstedt, Goodfellow and Stackebrandt 1991, 178[VP] (*Excellospora rubrobrunea* Agre and Guzeva 1975, 522)

ru.bro.bru′ne.a. L. adj. *ruber, bra brum* red; N.L. adj. *bruneus a um* brown; N.L. fem. adj. *rubrobrunea* reddish brown.

Coiled to spiral chains of 2–20 spores, some simple. Spore surface spiny. Reddish-brown substrate mycelium. Grows at 37–65°C and optimally at 45–55°C. Does not degrade adenine or cellulose. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: ATCC 49883, CIP 105486, DSM 43750, NBRC 15178, IMET 9705, INMI 2991, JCM 7345, KCTC 9493, VKM Ac-1470.

Sequence accession no. (16S rRNA gene): AF134069, EU637008.

Sequence accession no. (23S rRNA gene): AF134081.

Sequence accession no. (16S–23S rRNA ITS): AF134104.

27. **Actinomadura rudentiformis** le Roes and Meyers 2007, 48[AL]

ru. den. ti. for′mis. L. masc. n. *rudens* rope; L. adj. suff. *-formis* like, in the shape of; N.L. fem. adj. *rudentiformis* shaped like a rope.

Spores have not been detected. Cream-colored substrate mycelium with a sparse white aerial mycelium formed on oatmeal agar. Wrinkled, cream-colored substrate mycelium, but no sporulation on yeast extract-malt extract agar. White substrate mycelium but does not sporulate on inorganic salts-starch agar. Pigments are not produced on glycerol-asparagine, peptone-yeast extract-iron, or tyrosine agars. Rope-like or fiber-like growth visible under scanning electron microscopy. Growth occurs at 30, 37, and 45°C, but not at 4°C or pH 4.3. Degrades adenine, Tween 80, and xylan. Guanine and starch are weakly degraded. Hydrolyzes hippurate, but not allantoin, pectin, or urea. Lecithinase, lipase, and proteolytic activities are not observed on egg-yolk agar. Does not produce H_2S or reduce nitrate. Inositol, inulin, melezitose (weak), ribose (weak), salicin (weak), sodium acetate, and sucrose are used as sole carbon sources, but not sodium citrate. DL-α-Amino-*n*-butyric acid, L-arginine, L-cysteine, L-histidine, L-hydroxyproline, L-methionine, L-phenylalanine, potassium nitrate, L-servine, L-threonine, and L-valine are used as sole carbon and nitrogen sources. Resistant to kanamycin (10 μg/ml), neomycin (30 μg/ ml), oleandomycin (100 μg/ml), penicillin G (10 IU), rifampin (50 μg/ml), and tobramycin (50 μg/ml), but is sensitive to cephaloridine (100 μg/ml), gentamicin (100 μg/ml), lincomycin (100 μg/ml), streptomycin (100 μg/ml), and vancomycin (50 μg/ml). Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil taken from the banks of the Gamka River in the Swartberg Nature Reserve, Western Cape Province, South Africa.

DNA G+C content (mol%): not determined.

Type strain: HMC1, DSM 44962, JCM 14907, NRRL B-24458.

Sequence accession no. (16S rRNA gene): DQ285420.

28. **Actinomadura rugatobispora** (Miyadoh, Tohyama, Amano, Shomura and Niida 1985) Miyadoh, Amano, Tohyama and Shomura 1990, 1909[VP] (*Microbispora viridis* Miyadoh, Tohyama, Amano, Shomura and Niida 1985, 281[VP])

ru.ga.to.bi.spo′ra. L. part. adj. *rugatus* wrinkled; Gr. pref. *bi* twice; Gr. n. *spora* a seed and, in biology, a spore; N.L. n. *rugatobispora* organism forming wrinkled paired-spores, referring to spore morphology.

Aerial hyphae differentiate into a non-sporogenous main axis which bears spore-bearing side branches. Spores are oval (1.9–1.2 × 1.4–2.0 μm). Usually two but sometimes three spores per chain. Spore surface rugose with vertical ridges (Figure 408). Aerial mycelium is grayish green and the substrate mycelium pastel yellow on oatmeal agar. The substrate mycelium is pale yellowish brown on inorganic salts-starch agar. Grows at 25–35°C. Does not require vita-

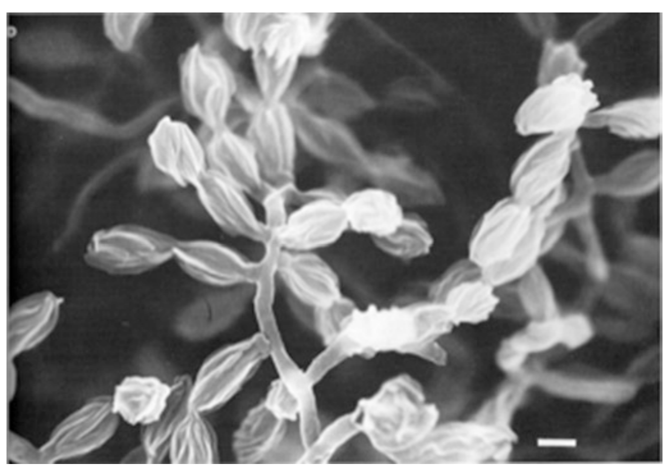

FIGURE 408. SEM of *Actinomadura rugatobispora* SF 2240[T] (IFO 14382[T]). Usually two but sometimes three spores per chain. Spore surface rugose with vertical ridges. Bar = 1 μm. (Reproduced with permission from S. Miyadoh, S. Amano, and T. Shomura. Atlas of Actinomycetes, Society for Actinomycetes Japan.)

min B for growth. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): 73 (T_m).

Type strain: SF2240, ATCC 51643, CIP 105482, DSM 44130, NBRC 14382, JCM 3366, NRRL B-16566.

Sequence accession no. (16S rRNA gene): U49010.

Sequence accession no. (23S rRNA gene): AF134082.

Sequence accession no. (16S–23S rRNA ITS): AF134105.

29. **Actinomadura spadix** Nonomura and Ohara 1971d, 911[AL]

spa′dix. L. fem. adj. *spadix* chestnut-colored (referring to the color of the substrate mycelium).

Short spore chains with 5–10 spores in small, round spore masses (pseudosporangia) formed on long aerial hyphae. Sporulation observed on soil extract agar and partly on oatmeal-yeast-glucose agar. Spore surface smooth (Figure 409). Glycerol-asparagine agar: aerial mycelium absent; substrate mycelium grayish brown, and diffusible pigment reddish-gray or grayish brown. Oatmeal agar: aerial mycelium light grayish-yellowish brown; substrate mycelium grayish brown, and diffusible pigment reddish-gray or grayish brown. Yeast extract-malt extract agar: aerial mycelium absent; substrate mycelium dark brown, and diffusible pigment brown. Grows at 30°C, but not at 25 or 37°C. Does not degrade Tweens 20, 40, 60, and 80. Phenylalanine and valine are used as sole carbon sources, but not arginine or glutamine. Resistant to rifampin (10 µg/ml), but is susceptible to ampicillin (5 µg/ml), benzylpenicillin (25 µg/ml), carbenicillin (90 µg/ml), tobramycin (0.05 µg/ml), and tetracycline (20 µg/ml). Additional phenotypic properties are shown in Table 302 and Table 303.

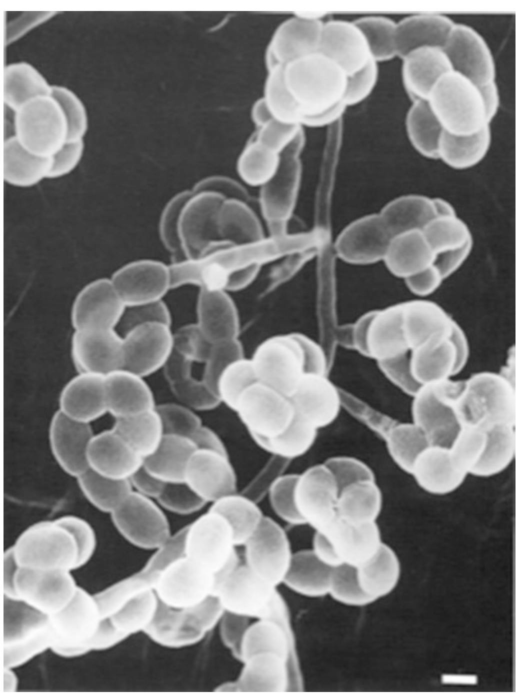

FIGURE 409. SEM of *Actinomadura spadix* MH 193-16 F4. Short spore chains with 5–10 spores in small, round spore masses (pseudosporangia) formed on long aerial hyphae. Spore surface smooth. Bar = 1 µm. (Reproduced with permission from M. Hamada and T. Shomura. Atlas of Actinomycetes, Society for Actinomycetes Japan.)

Source: soil.

DNA G+C content (mol%): 66.4 (T_m).

Type strain: ATCC 27298, CBS 261.72, BCRC (formerly CCRC) 13386, CIP 105479, DSM 43459, NBRC 14099, IMET 9752, JCM 3146, KCC A-0146, KCTC 9252, NCIB 11118, NRRL B-16128.

Sequence accession no. (16S rRNA gene): AF163120, AB364581.

Sequence accession no. (23S rRNA gene): AF163142.

Sequence accession no. (16S–23S rRNA ITS): AF163131.

Additional comments: according to Nonomura and Ohara (1971c), Actinomadura spadix requires B vitamins for growth. Phylogenetic data (16S and 23S rRNA) suggests that this strain is misclassified in the genus *Actinomadura* and may represent a new genus though additional data are needed to clarify its taxonomic status.

30. **Actinomadura umbrina** Galatenko, Terekhova and Preobrazhenskaya 1987, 179[VP] (Effective publication: Galatenko, Terekhova and Preobrazhenskaya 1981, 803.)

um.bri′na. N.L. fem. adj. *umbrina* wood brown.

Short spore chains may be straight, hooked or spiral, often branching. Smooth spore surface. Substrate mycelium is brown or black as are soluble pigments. White scanty aerial mycelium produced. Good growth occurs on mineral (Gauze 1), Czapek's, glycerol-nitrate, glycerol asparagine, and inorganic salts-starch agars. Does not grow on carbon utilization agar supplemented with different sugars, including glucose. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: ATCC 49502, CIP 105485, DSM 43927, NBRC 14346, IMET 9746, INA 2309, JCM 6837, NRRL B-16244, VKM Ac-1086.

Sequence accession no. (16S rRNA gene): AF163121, AJ293713.

Sequence accession no. (23S rRNA gene): AF123143.

Sequence accession no. (16S–23S rRNA ITS): AF163132.

31. **Actinomadura verrucosospora** Nonomura and Ohara 1971d, 908[AL]

ver.ru.co.so.spo′ra. L. fem. adj. *verrucosa* warty; Gr. n. *spora* seed; N.L. n. *verrucosospora* organism forming warty spores, referring to the warty surface of the spores.

Spore chains (5–12 spores per chain) hooked or curled or spirals of one turn, arranged in tufts on long aerial hyphae. Spores elliptical. Spore surface warty. Glycerol-asparagine agar: moderate growth; aerial mycelium absent; substrate mycelium bright red, and no diffusible pigment. Inorganic salts-starch agar: poor growth; surface farinaceous to granular; aerial mycelium white; substrate mycelium yellowish white, and no diffusible pigment. Oatmeal agar: good growth; surface farinaceous; aerial mycelium pink turning blue with maturity; substrate mycelium orange to pink, and no diffusible pigment. Oatmeal-nitrate agar: good growth; surface slightly farinaceous; aerial mycelium white to grayish; substrate mycelium white to pink, and no

diffusible pigment. Yeast extract-malt extract agar: moderate to good growth; surface farinaceous; aerial mycelium white; substrate mycelium yellowish, and no diffusible pigment. Grows at 10–37°C. Does not degrade RNA or xylan. Resistant to ampicillin (10 µg/ml), benzylpencillin (25 µg/ml), carbenicillin (120 µg/ml), and rifampin (10 µg/ml), but is susceptible to lincomycin (10 µg/ml) and tetracycline (20 µg/ml). Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil in Japan.

DNA G+C content (mol%): 69.0 (T_m).

Type strain: ATCC 27299, CBS 258.72, CCM 3492, BCRC (formerly CCRC) 13408, CIP 105480, DSM 43358, DSM 43550, IMET 9588, JCM 3147, KCC A-0147, NCIMB 11119, NRRL B-16129, RIA 1503, VKM Ac-668.

Sequence accession no. (16S rRNA gene): U49011.

Sequence accession no. (23S rRNA gene): AF134083.

Sequence accession no. (16S–23S rRNA ITS): AF134106.

32. **Actinomadura vinacea** Lavrova and Preobrazhenskaya 1975, 486[AL]

vi.na′ce.a. L. fem. adj. *vinacea* of or belonging to wine, referring to the brownish-red color of the substrate mycelium.

Short, straight spore chains, arranged in small clusters on moderately branched hyphae of the aerial mycelium. Spore surface irregular. Czapek-sucrose agar: poor growth; aerial mycelium pink or absent; substrate mycelium brownish red, and diffusible pigment pale lilac to red. Inorganic salts-starch agar (Gauze 1): poor growth; surface slightly velvety; aerial mycelium white to gray; substrate mycelium colorless, and diffusible pigment pale pink. Oatmeal agar: poor growth; surface dull leathery; aerial mycelium absent; substrate mycelium pink to red, and no diffusible pigment. Peptone glucose medium: poor to moderate growth; surface cartilaginous; aerial mycelium absent; substrate mycelium brownish red, and diffusible pigment dark red. Yeast extract-malt extract agar: poor growth; surface leathery; aerial mycelium absent; substrate mycelium dark brown-red, and diffusible pigment red. Additional phenotypic properties are shown in Table 302 and Table 303.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: ATCC 33581, CIP 105481, DSM 43765, NBRC 14688, IMET 9574, IMET 9673, INA 1682, JCM 3325, KCC A-0325, KCTC 9344.

Sequence accession no. (16S rRNA gene): AF134070.

Sequence accession no. (23S rRNA gene): AF134084.

Sequence accession no. (16S–23S rRNA ITS): AF134107.

33. **Actinomadura viridilutea** (Agre and Guzeva 1975) Zhang, Kudo, Nakajima and Wang 2001, 381[VP] (*Excellospora viridilutea* Agre and Guzeva 1975)

vi.ri.di.lu′te.a. L. adj. *viridis* green; L. adj. *luteus* yellow; N.L. fem. adj. *viridilutea* green-yellow.

Spore chains hooked to spiral. Spore surface spiny. Substrate mycelium is yellow; aerial mycelium is bluish green. Grows at 37–65°C and optimally at 45–55°C. Does not degrade cellulose. The following carbon sources were used when assayed in Czapek's agar without sucrose as basal medium: acetate, arabinose (weak), citrate (weak), dulcitol (weak), galactose, glucose, glycerol, inositol, lactose, maltose, mannitol, raffinose, rhamnose, starch, sucrose, and xylose (weak). Asparagine, NH_4, urea, and tyrosine are used as nitrogen sources. Does not show antibacterial or antifungal activities against *Bacillus mycoides*, *Bacillus subtilis*, *Escherichia coli*, *Sarcina lutea*, *Serratia marcescens*, *Staphylococcus aureus*, *Streptomyces globisporus*, *Streptomyces fluorescens*, *Streptomyces griseus*, or *Streptomyces levoris* or against *Aspergillus niger*, *Fusarium oxysporum*, *Penicillium notatum*, and *Saccharomyces cerevisiae*. Additional phenotypic properties are shown in Table 302 and Table 303.

DNA G+C content (mol%): not determined.

Type strain: ATCC 33925, BCRC (formerly CCRC) 13638, DSM 44433, NBRC 14480, IMET 9742, INMI 187, JCM 3398, JCM 7346.

Sequence accession no. (16S rRNA gene): D86943.

Sequence accession no. (23S rRNA gene): AF134087.

Sequence accession no. (16S–23S rRNA ITS): AF134110.

Additional comments: Actinomadura viridilutea can be differentiated from *Actinomadura rubrobrunea* by the solubility, light absorbance, and pH color change of its pigments, by its antimicrobial response, and the color of its substrate mycelium.

34. **Actinomadura viridis** (Nonomura and Ohara 1971b) Miyadoh, Anzai, Amano and Shomura 1989, 156[VP] (*Microtetraspora viridis* Nonomura and Ohara 1971b, 5[AL])

vi′ri.dis. L. fem. adj. *viridis* green.

Spores in straight chains. Spore surface smooth. Substrate mycelium pale yellowish-brown on Hickey–Tresner agar. Good sporulation on inorganic salts-starch and MGA agars, but none on Czapek oatmeal or soil extract agars. Grows at 20–45°C. Resistant to neomycin (1 µg/ml), streptomycin (4 µg/ml), cephalotin (35 µg/ml), ampicillin (15 µg/ml), and rifampin (10 µg/ml), but is susceptible to benzylpenicillin (25 µg/ml) and tetracycline (20 µg/ml). Additional phenotypic properties are shown in Table 302 and Table 303.

Sequence accession no. (23S rRNA gene): AF134085.

Sequence accession no. (16S–23S rRNA ITS): AF134108.

35. **Actinomadura yumaensis** Labeda, Testa, Lechevalier and Lechevalier 1985, 333[AL]

yu.ma.en′sis. N.L. fem. adj. *yumaensis* of or belonging to Yuma County, Arizona, USA, the source of the soil sample from which the type strain was isolated.

Spore chains are short (mean, 20 spores per chain), loosely coiled and usually borne on branched, and almost verticillate aerial sporophores. Spores are ovoid and measure 0.6–0.8 × 1.0–1.4 µm. Spore surface smooth (Figure 410). Bennett-sucrose agar: good growth; aerial mycelium absent; convoluted substrate mycelium yellowish gray to grayish brown; substrate mycelium dark grayish-yellowish brown, and diffusible pigment orange. Inorganic salts-starch agar: poor growth; white aerial mycelium; substrate

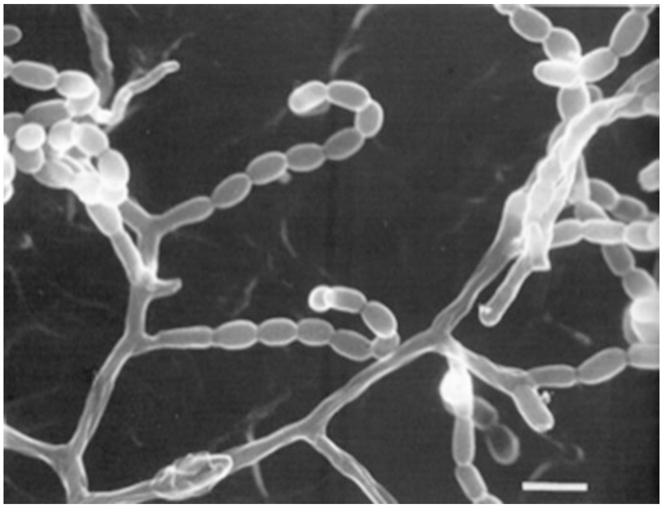

FIGURE 410. Electron micrograph of *Actinomadura yumaensis* IFO 14689[T]. Spore chains are coiled and usually borne on branched, almost verticillate aerial sporophores. Bar = 2 µm. (Reproduced with permission from S. Miyadoh and S. Amano. Atlas of Actinomycetes, Society for Actinomycetes Japan.)

mycelium colorless, and no diffusible pigment. Oatmeal agar: moderate growth; surface flat waxy; grayish yellow; moderate white aerial mycelium; substrate mycelium grayish yellow, and no diffusible pigment. Yeast-extract-malt extract agar: good growth; surface raised waxy; convoluted colonies yellowish gray to grayish-yellowish brown; aerial mycelium absent; substrate mycelium dark yellowish brown, and diffusible pigment orange. Grows at 10–45°C. Arginine and sucrose are used as sole carbon sources. Resistant to ampicillin (15 µg/ml), benzylpenicillin (25 µg/ml), cephaloridine (10 µg/ml), cephalotin (35 µg/ml), cephamandole (30 µg/ml), neomycin (7 µg/ml), rifampin (10 µg/ml), streptomycin (16 µg/ml), and tetracycline (40 µg/ml). Additional phenotypic features are shown in Table 302 and Table 303.

Source: soil sample collected in Yuma County, Arizona.

DNA G+C content (mol%): not determined.

Type strain: LL-C23024, ATCC 43060, CIP 105436, NBRC 14689, JCM 3369, KCTC 9495, NRRL 12515.

Sequence accession no. (16S rRNA gene): AF163122.

Sequence accession no. (23S rRNA gene): AF163144.

Sequence accession no. (16S–23S rRNA ITS): AF163133.

Species *incertae sedis*

a. **"Actinomadura azurea"** Nakamura and Isono 1983, 1468

Produces cationomycin.

Type strain: ICM 2033.

b. **"Actinomadura luzonensis"** Tomita, Hoshino, Sasahira and Kawaguchi 1980, 1098

Produces the antitumor antibiotic complex BBM-928.

Type strain: ATCC 31491 (G455–101).

c. **"Actinomadura pulveracea"** Iwami, Kiyoto, Nishikawa, Terano, Kohsaka, Aoki and Imanaka 1985, 835

Produces antitumor antibiotics FR-900405 and FR-900406.

Type strain: No. 6049.

d. **"Actinomadura albolutea"** Tohyama, Miyadoh, Ito, Shomura, Ito and Ishikawa 1984, 1144

The placement of this species in the genus *Actinomadura* is doubtful. Morphologically, Actinomadura albolutea resembles *Nocardiopsis* however, the presence of maduroe in whole-cell hydrolysates, phospholipids of type PIV, and MK-9(H_4) as major menaquinones indicate that this micro-organism is clearly differentiated from *Nocardiopsis*. Produces an indole-*N*-glycoside antibiotic SF-2140.

Type strain: FERM-BP 386 (SF2140).

Genus IV. **Spirillospora** Couch 1963, 61[AL]

Michael Goodfellow and Martha E. Trujillo

Spi.ril. lo.spo′ra. L. n. *spira* a spiral; N.L. dim. neut. n. *spirillum* a short spiral; Gr. n. *spora* a seed and, in biology, a spore; N.L. fem. n. *Spirillospora* an organism with spores in spirals.

Aerobic, Gram-stain-positive, chemo-organotrophic, mesophilic actinomycetes which **form spherical to vermiform spore vesicles** (5.0–24.0 µm in diameter) **on aerial mycelia**. **Spore vesicles contain numerous spores arranged in coiled and branched chains. Spores are rod-shaped or curved** (0.5–0.7 × 2.0–6.0 µm) **and are motile by means of one to seven subpolar flagella**. The hyphae of the substrate and aerial mycelia are 0.2–1.0 µm thick, branched, and septate. **The substrate mycelium is white to pale yellow or pale buffy pink to red; the aerial mycelium is usually white. Cell-wall peptidoglycan contains *meso*-diaminopimelic acid; madurose is the characteristic sugar of whole-organism hydrolysates.** Grows at 18–35°C. Predominant menaquinones are MK-9(H_4) and MK-8 (H_4).

DNA G+C content (mol%): 71.0–73.0 (T_m, Bd).

Type species: **Spirillospora albida** Couch 1963, 61[AL].

Further descriptive information

Phylogeny. Members of the genus *Spirillospora* were originally classified in the family *Streptosporangiaceae*, but it is evident from chemotaxonomic, nucleic acid reassociation, and comparative 16S rRNA sequencing studies that the genus is a *bona fide* member of the family *Thermomonosporaceae* (Stackebrandt et al., 1997, 1981; Zhang et al., 2001). However, the type strains of the two constituent species, *Spirillospora albida* and *Spirillospora rubra*, are well separated in the *Thermomonosporaceae* 16S rRNA gene tree

(Figure 398 in *Thermomonosporaceae* chapter). These organisms share a 16S rRNA gene similarity of 96.8%, a value which corresponds to 58 differences out of a total of 1444 nucleotides. *Spirillospora albida* IFO 12248$^{\mathrm{T}}$ and *Spirillospora rubra* JCM 6875$^{\mathrm{T}}$ share the highest 16S rRNA gene similarity with *Actinomadura rudentiformis* DSM 44962$^{\mathrm{T}}$ (97.7% and 97.2%, respectively). The type strains of *Spirillospora albida* and *Spirillospora rubra* have also been shown to be distantly related in an analysis of 23S rRNA gene sequences (Zhang et al., 2001). In addition, the type strain of *Spirillospora albida* shares a 70% 16S–23S rRNA internal transcribed spacer (ITS) sequence identity with several *Actinomadura* species, a value much higher than those (>40%) reported between many *Actinomadura* species (Zhang et al., 2001). In contrast, Zhang and his colleagues found that the type strain of *Actinomadura rubra* exhibits only 30–40% 16S–23S ITS sequence similarity to those of all other species in the family *Thermomonosporaceae*.

Cell morphology. *Spirillospora* strains form substrate and aerial mycelia. The hyphae are branched and septate and are 0.2–1.0 µm in diameter (Couch and Bland, 1974). Spore vesicles (sporangia) produced on aerial mycelia are usually spherical with a diameter of 5.0–24.0 µm; the mean diameter is 10 µm (Figure 411). Subspherical to elongated or club-shaped and vermiform spore vesicles are also formed (Couch, 1963). At the initiation of spore vesicle development, the end of an aerial hypha winds into a coil that is enclosed in a common sheath (Bland and Couch, 1981; Lechevalier et al., 1966; Locci and Petrolini-Baldan, 1971; Vobis, 1985). In some cases it appears that the first coils are temporarily free (Vobis and Kothe, 1985). The coiled sporogenous hyphae are branched and fragment into oblong segments that differentiate into spore-size segments (Lechevalier et al., 1966; Vobis, 1985).

The spores are short to long rods, and are frequently curved (0.5–0.7 × 2–7 µm) (Couch and Bland, 1974). A subpolarly inserted tuft of one to seven flagella gives the spores a slight motility which can become more vigorous in the presence of an energy source (Higgins et al., 1967). In addition to the spores enclosed in spore vesicles, free, exposed spores in regular or irregular coils may be found among the aerial hyphae. When flooded with water, the coils break up into rod-shaped to curved spores that subsequently become motile. Conidia-like structures in moniliform arrangement may be produced by the substrate mycelium (Couch, 1963). The septa involved in spore formation are double-layered [cross wall type 2 of Williams et al. (1973)]. Aerial hyphae are additionally covered with a thick sheath from which the spore vesicular envelope originates (Lechevalier et al., 1966; Vobis and Kothe, 1985). *Spirillospora albida* forms spore vesicles on Czapek, peptone-Czapek, and oatmeal agars and *Spirillospora rubra* on cornmeal-soil agar (Vobis and Kothe, 1989) and artificial soil agar (Henssen and Schäfer, 1971).

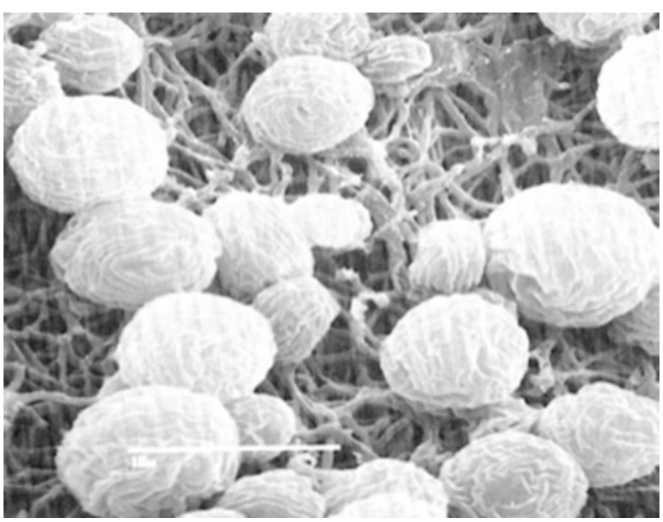

FIGURE 411. *Spirillospora albida* ATCC 15331. Scanning electron micrograph of spherical spore vesicles formed on the aerial mycelium after incubation for 15 d (3200×). Bar = 10 µm.

Nutrition and growth conditions. Spirillosporae can be cultured on various complex media. They grow well on Czapek, peptone-Czapek, and oatmeal agars and moderately on casein and tyrosine agars. Colonies are compact and elevated, sometimes with protruberances on casein, peptone-Czapek, and tyrosine agars. Flattish or confluent colonies are formed on Czapek and oatmeal agars. Some strains produce a blue confluent pigment called spirillomycin, which shows antibiotic activity against some Gram-stain-positive bacteria (Domnas, 1968; McInnis and Domnas, 1970). The pigment producing strains use amylopectin, galactose, glucose, maltose, and sucrose as carbon sources for growth (Domnas, 1970). *Spirillospora* grows well at 18–35°C (Couch and Bland, 1974).

Cell-wall composition. The cell-wall peptidoglycan of *Spirillospora* strains contain *meso*-diaminopimelic acid, and whole-organism hydrolysates contain the diagnostic sugar madurose (Lechevalier and Lechevalier, 1970c; Yamaguichi, 1965); this means that they have a wall chemotype III and a sugar pattern B according to the scheme of Lechevalier and Lechevalier (1970b). The type strain of *Spirillospora albida* contains diphosphatidylglycerol, phosphatidylinositol, and phosphatidylinositol mannosides as major polar lipids (Zhang et al., 2001) and hence has a type 1 phospholipid pattern (Lechevalier et al., 1981) though previous workers reported a type II pattern for this organism (Hasegawa et al., 1978). The predominant menaquinones are MK-9(H_4) and MK-9(H_6) (Collins et al., 1984). Spirillosporae contain major amounts of hexadecanoic ($C_{16:0}$; 20–26% of total fatty acids), octadecenoic ($C_{18:1}$; 21–27%), 14-methylpentadecanoic ($C_{16:0}$ iso; 5–11%), and 10-methyloctadecanoic (tuberculostearic) acids (Zhang et al., 2001), that is, they have a fatty acid type 3a pattern *sensu* Kroppenstedt (1985).

Ecology. *Spirillospora* strains have been isolated from soil, albeit infrequently, by using baits (pollen for the isolation of *Spirillospora albida* and hair for the recovery of *Spirillospora rubra*). However, these organisms accounted for less than 1% of the "sporangiate" actinomycetes isolated from soil using baits (Schäfer, 1973). One part of the life cycle of spirillosporae is adapted to the aquatic milieu. Motile zoospores are able to colonize pollen grains that float on the surface of water and constitute their natural substrate. Mycelia are developed, forming spore vesicles when in contact with air. The spore vesicles are considered to be resistant stages against desiccation. When flooded with water, the zoospores are released from the spore vesicles through either a rupture in the envelope or through a large, irregular pore (Couch, 1963).

Isolation procedures

Spirillosporae have been isolated from soil by baiting with natural substrates (Bland and Couch, 1981; Couch, 1954; Schäfer, 1973). A small amount of soil, approximately one level teaspoonful, is placed in a sterile Petri dish and flooded with sterile water

(distilled water or filtered soil or charcoal water extracts may be used). Various types of pollen [from members of the genera *Liquidamber*, *Pinus and Sparanium*; (Schäfer, 1973)] or other natural substrates such as hair, snakeskin, or boiled grass are added as baits and after incubation for 1–4 weeks the baits are examined with a binocular dissecting microscope (×100). Aerial mycelium and spore vesicles can be recognized at the surface of the water by their glistening appearance. Pollen baits bearing spore vesicles are picked up with a thin needle and transferred to the surface of agar media in small Petri dishes. Individual spore vesicles are separated from the baits and rolled on the agar surface to free them from contaminating bacteria. The cleaned spore vesicles are used as an inoculum for pure cultures. Various complex media support the growth of *Spirillospora* strains. *Spirillospora albida* grows well on Czapek, peptone-Czapek, and oatmeal agars whereas *Spirillospora rubra* prefers half-concentrated corn meal agar (Difco) supplemented with sterilized garden soil (50 g/liter) or half concentrated skim milk agar (Difco; Schäfer, 1973).

Maintenance procedures

Subcultures should be made after a period of 12 weeks. For long-term preservation, the organisms must be lyophilized by using standard procedures employed for aerobic actinomycetes, preferably using well-sporulating cultures. A simple, reliable, and quick method involves nitrogen cryopreservation of living cells in small polyvinyl tubes ("straws") at –196°C (Hoffman, 1989a, 1989b).

Differentiation of the genus *Spirillospora* from other genera

Spirillospora strains can be distinguished from the other three genera classified in the family *Thermomonosporaceae* using a range of chemotaxonomic, morphological and phylogenetic data (Table 298, see chapter on Family *Thermomonosporaceae*). Members of the genus can be easily confused on morphological grounds with those of some species of *Streptosporangium*. All strains belonging to these taxa have multispored, usually spherical, spore vesicles borne on aerial hyphae. However, members of the two genera can be distinguished on the basis of menaquinone and polar lipid composition (Collins et al., 1984; Zhang et al., 2001). In addition, spirollosporae, unlike streptosporangiae, produce zoospores.

Taxonomic comments

Spirillospora albida, the type species of the genus, is closely related to many *Actinomadura* species (Figure 398). The 16S rRNA and 23S rRNA gene sequences of *Spirillospora albida* and some *Actinomadura* strains exhibit much higher similarity than the sequence similarity between most representatives of *Actinomadura* species, as is the case with 16S–23S ITS sequences (Zhang et al., 2001). These data strongly suggest that *Spirillospora albida* has a very close evolutionary relationship with some *Actinomadura* species. In contrast, corresponding data on *Spirillospora rubra* shows that this organism is only distantly related to *Spirillospora albida* and to most other taxa classified in the family *Thermomonosporaceae*, which suggests that this species may merit generic status. However, further comparative taxonomic studies are needed on additional *Spirillospora* strains to clarify their relationships with one another and with members of other genera assigned to the family *Thermomonosporaceae*, notably the genus *Actinomadura*.

Differentiation of species of the genus *Spirillospora*

The two *Spirillospora* species can be distinguished by the characteristic colors of their substrate mycelia. The colonies of *Spirillospora albida* are white to pale yellow whereas those of *Spirillospora rubra* are red to reddish brown.

List of species of the genus *Spirillospora*

1. **Spirillospora albida** Couch 1963, 65[AL]

al′bi. da. L. fem. adj. *albida* whitish.

Spherical spore vesicles (mean, 10 µm in diameter; range, 5.0–24.0 µm) are formed at the tips of aerial hyphae on Czapek, peptone-Czapek, and oatmeal agars. Subspherical to elongated or club-shaped and vermiform spore vesicles are also formed. Spores are rod-shaped, frequently curved (0.5–0.7 × 2.0–6 µm), and weakly motile.

The color of the substrate mycelium is white to pale yellow or buffy pink; the aerial mycelium is white. After 8 weeks, colonies reach diameters up to 13 mm on Czapek, peptone-Czapek, and oatmeal agars, and diameters 5–10 mm on casein and tyrosine agars. A pale yellowish soluble pigment is produced on casein agar and a clay-colored pigment on tyrosine agar. Some strains produce a blue soluble pigment on peptone-Czapek agar. Good growth occurs at 18–35°C and optimum growth at 25°C. Degrades casein and L-tyrosine.

Source: soil.

DNA G+C content (mol%): 70.0–72.0 (T_m) for the type strain and 72.9 (B_d) for strain UNCC 761.

Type strain: ATCC 15331, CBS 291.04, DSM 43034, NBRC 12248, IMET 9031, JCM 3041, NRRL B-3350, VKM Ac-926.

Sequence accession no. (16S rRNA gene): D85498.

Sequence accession no. (23S rRNA gene): AF134088.

Sequence accession no. (16S–23S rRNA ITS): AF134111.

2. **Spirillospora rubra** (*ex* Schäfer 1973) nom. rev. *Spirillospora rubra* Schäfer 1973, 199[AL]

ru′bra. L. fem. adj. *rubra* red.

Hyphae of substrate mycelium are branched (0.4–0.9 µm in diameter), as are aerial hyphae (0.6–1.2 µm in diameter). Spherical spore vesicles, with a diameter of 10.0–25.0 µm, are formed at the tips of aerial hyphae on artificial soil agar and on cornmeal-soil agar.* Rod-shaped spores are frequently slightly curved (0.8 × 1.8–2.8 µm), and weakly motile.

Substrate mycelium is red to reddish brown; the aerial mycelium is white. Good growth occurs on casein and yeast extract-starch agars, and moderate growth on oatmeal-yeast extract, peptone, starch, and tyrosine agars. Grows well at 20–37°C. Degrades casein, but not L-tyrosine. Nitrate is not reduced.

Source: soil.

DNA G+C content (mol%): not determined.

Type strain: CBS 571.75, JCM 6875.

Sequence accession no. (16S rRNA gene): AF163123

Sequence accession no. (23S rRNA gene): AF163145.

Sequence accession no. (16S–23S rRNA ITS): AF163134.

oatmeal-nitrate agar (Prauser and Bergholz, 1974) and peptone-glucose medium ~~(Prauser and Falta,~~ 1968).

*Difco cornmeal agar: cornmeal, 8.5 g, agar, 7.5 g, sterile garden soil, 50 g, distilled water, 1000 ml.

Order XVI. **Incertae sedis**

Previously classified within the *Pseudonocardiaceae* (Garrity et al., 2005), this placement of *Thermobispora* is not consistent with chemotaxonomic markers or subsequent rRNA gene analyses. The cell-wall diamino acid is *meso*-diaminopimelic acid; whole-cell hydrolysates contain the sugars madurose and galactose; the major menaquinone is MK-9(H_0); and the phospholipid pattern is type PIV. These properties distinguish it from the *Pseudonocardiaceae*. Moreover, in analyses of the 16S rRNA genes, *Thermobispora* appears as a deep lineage within the *Streptosporangiales* but without a clear association to any of the described families (Ludwig et al., 2012). Given the ambiguities, this genus is reclassified in an order *incertae sedis* in this volume.

Genus I. **Thermobispora** Wang, Zhang and Ruan 1996, 937[VP]

Seung Bum Kim

Ther.mo.bi.spo′ra. Gr. adj. *thermos* hot; Gr. adj. *bis* two; Gr. fem. n. *spora* seed; N.L. fem. n. *Thermobispora* high temperature, two-spored organism.

Gram-stain-positive, aerobic, non-acid-fast, **thermophilic** organisms that produce substrate hyphae (0.5–0.8 µm in diameter). **The aerial mycelia branch monopodially and bear longitudinal pairs of spores**, usually arranged alternately on side branches arising from the main hyphae. **The smooth-surfaced spores are oval to spherical and nonmotile**. Fragmentation of mycelia is not observed on agar or in liquid media. Neither sclerotia, sporangia, nor any other special structures are formed. The cell wall contains a major amount of ***meso*-diaminopimelic acid**, and **the whole-cell hydrolysates contain madurose and galactose**. **MK-9(H_0) is the major menaquinone**. **The phospholipid pattern is type PIV**, including phosphatidylethanolamine and a small amount of glucosamine-containing phospholipids. The major fatty acid is 14-methylpentadecanoic acid ($C_{16:0}$ iso).

DNA G+C content (mol%): 71.

Type species: **Thermobispora bispora** (Henssen 1957) Wang, Zhang and Ruan 1996, 937[VP].

Further descriptive information

Thermobispora is classified with an order *incertae sedis* within this volume. The spores of the type and only species, *Thermobispora bispora*, are usually 1.2–2.0 µm in diameter, but in liquid media spores with a diameter of 3 µm have been observed. The aerial mycelium is white, and the substrate mycelium yellow or yellowish brown on ISP 4 agar medium. Soluble pigments are not produced. The predominant menaquinone of *Thermobispora bispora* is MK-9(H_0), with MK-9(H_2) and MK-9(H_4) present in smaller amounts. The strains of *Thermobispora bispora* can grow at 65°C, but not at 35°C or lower temperatures. The 16S rRNA gene sequences of two *Thermobispora bispora* strains (strains ATCC 19993[T] and JCM 3082) were determined by Wang et al. (1996).

Enrichment and isolation procedures

Thermobispora strains have been isolated from (decaying) manure samples. Colonies can be obtained using selective media for actinobacteria and incubation at 50°C or higher temperatures.

Maintenance procedures

Thermobispora bispora can be maintained at temperatures between 50 and 65°C on ISP medium 4, Bennett's agar, oatmeal agar or rolled oats mineral medium (DSM medium no. 84). For long-term preservation, storage of the mycelial or spore suspensions in 20% (v/v) glycerol at −20°C, or lyophilization is recommended.

Differentiation from closely related taxa

The production of aerial spores in longitudinal pairs from monopodially branching aerial mycelia distinguishes *Thermobispora* from the related genera of the family *Pseudonocardiaceae*. The presence of menaquinone MK-9(H_0) in *Thermobispora* is also a useful marker to distinguish the genus from other genera of the family. Unlike most genera of the family *Pseudonocardiaceae* that have type II or III phospholipids, *Thermobispora* has a type IV phospholipid profile. In addition, strains of *Thermobispora* are obligate thermophiles, growing at temperatures between 50 and 65°C, which is comparable to the growth range (20–62.5°C) of another thermophilic genus within the family, *Thermocrispum*. *Thermobispora* can also be differentiated from related genera using the 16S rRNA gene restriction fragment patterns, as suggested by Cook and Meyers (2003).

Taxonomic comments

Thermobispora bispora was originally described as "*Thermopolyspora bispora*" Henssen 1957, and later transferred to *Microbispora* as "*Microbispora bispora*" Lechevalier 1965. However, the strains classified as "*Microbispora bispora*" differed in many ways from the other validly named species of *Microbispora*, in the levels of DNA homology, growth temperature, predominant menaquinones, phospholipid type, major fatty acid profiles and the electrophoretic pattern of ribosomal proteins (Miyadoh et al., 1990; Ochi et al., 1993). Finally, Wang et al. (1996) sequenced the 16S rRNA gene of strains "*Microbispora bispora*" JCM 3082 and "*Microbispora bispora*" ATCC 19993, and combined these results with chemotaxonomic and DNA–DNA hybridization data to classify the two strains in the genus *Thermobispora*. In addition, Wang and colleagues (1996) highlighted the thermophilic lifestyle of *Thermobispora bispora* to support the reclassification of these strains.

Previously, *Thermobispora* was assigned to the family *Pseudonocardiaceae*, with *Pseudonocardia* and *Actinopolyspora* as neighboring genera (Garrity et al., 2005). However, this assignment was

not supported by chemotaxonomic markers and analyses of the 16S rRNA genes performed for this volume suggested that *Thermobispora* appeared as a deep lineage within the *Streptosporangiales*, but without a clear association to any of the described families (Ludwig et al., 2012). Because this assignment was not strongly supported by chemotaxonomic markers, the genus is placed in an order *incertae sedis*.

Miscellaneous comments

Thermobispora bispora ATCC 19993^T was reported to have four copies of rRNA operons, containing two distinct types of 16S rRNA genes, both transcriptionally active (Wang et al., 1997). Considerable numbers of nucleotide differences between the two gene sequences exist, but the invariable or rarely invariable regions of both genes remain unchanged.

List of species of the genus *Thermobispora*

1. **Thermobispora bispora** (Henssen 1957) Wang, Zhang and Ruan 1996, 937^{VP} [*Thermopolyspora bispora* Henssen 1957, 395; *Microbispora bispora* (Henssen 1957) Lechevalier 1965, 141]

   bi.spo′ra. Gr. adj. *bis* two; Gr. fem. n. *spora* seed; N.L. fem. adj. *bispora* two spores.

   Substrate and aerial mycelia are formed, and longitudinal pairs of spores are borne on the branches of the aerial mycelium. The diameter of the spores is usually 1.2–2.0 μm, but occasionally spores with a diameter of 3 μm are observed in liquid culture. The aerial mycelium is white and the substrate mycelium is yellow or yellowish brown on ISP medium 4 and IFO328 medium. Soluble pigments have not been observed. Starch is not hydrolyzed. Negative for iodinin production and nitrate reduction. Inositol and rhamnose are utilized for growth, but not arabinose or glycerol. The type strain grows between 50 and 65°C but not at 35°C.

   Habitat: decaying manure.

   DNA G+C content (mol%): 71 (T_m).

   Type strain: ATCC 19993, CBS 139.67, NBRC 14880.

   Sequence accession no. (16S rRNA gene): U58523 (ATCC 19993).

Class II. **Acidimicrobiia** class. nov.

Paul R. Norris

A.ci.di.mi.cro.bi′i.a. N.L. neut. n. *Acidimicrobium* type genus of the type order; suff. *-ia* ending to denote a class; N.L. pl. neut. n. *Acidimicrobiia* the *Acidimicrobiales* class.

The class *Acidimicrobiia* was delineated on the basis of 16S rRNA gene sequence analyses and taxon-specific 16S rRNA signature nucleotides as for the subclass *Acidimicrobidae* Stackebrandt et al. 1997. The pattern of 16S rRNA signature nucleotides was revised as 242:284 (U–G), 291:309 (U–A), 316:337 (C–G), 819 (U), 952:1229 (C–G), and 1115:1185 (U–G) (Zhi et al., 2009). The class contains a single order, the type order *Acidimicrobiales*. The nomenclatural type is the genus *Acidimicrobium* Clark and Norris 1996, 1189^{VP} (Effective publication: Clark and Norris 1996, 790.)

References

Clark, D.A. and P.R. Norris. 1996. *Acidimicrobium ferrooxidans* gen. nov., sp. nov.: mixed culture ferrous iron oxidation with *Sulfobacillus* species. Microbiology *142*: 785–790.

Clark, D.A. and P.R. Norris. 1996. *In* Validation of the publication of new names and new combinations previously effectively published outside the IJSB. List no. 59. Int. J. Syst. Bacteriol. *46*: 1189–1190.

Stackebrandt, E., F.A. Rainey and N.L. Ward-Rainey. 1997. Proposal for a new hierarchic classification system, *Actinobacteria* classis nov. Int. J. Syst. Bacteriol. *47*: 479–491.

Zhi, X.-Y., W.-J. Li and E. Stackebrandt. 2009. An update of the structure and 16S rRNA gene sequence-based definition of higher ranks of the class *Actinobacteria*, with the proposal of two new suborders and four new families and emended descriptions of the existing higher taxa. Int. J. Syst. Evol. Microbiol. *59*: 589–608.

Order I. **Acidimicrobiales** Stackebrandt, Rainey and Ward-Rainey 1997, 483[VP]

Paul R. Norris

A.ci.di.mi.cro.bi′a.les. N.L. neut. n. *Acidimicrobium* type genus of the order; suff. *-ales* ending to denote an order; N.L. fem. pl. n. *Acidimicrobiales* the *Acidimicrobium* order.

In 2009, the emended description of the order *Acidimicrobiales* (Zhi et al., 2009) noted a single family, the *Acidimicrobiaceae*, with the pattern of 16S rRNA signature nucleotides as given for the subclass *Acidimicrobidae*, now the class *Acidimicrobiia*. Also in 2009, a second family of the order was proposed, the *Iamiaceae* (Kurahashi et al., 2009). Nucleotides U–A at positions 952:1229 in the type species of *Iamia*, the single genus in the family *Iamiaceae*, expand the pattern of 16S rRNA signature nucleotides given for the class *Acidimicrobiia* and the order *Acidimicrobiales*, which also includes C–G at positions 952:1229 (Zhi et al., 2009).

A large number of uncultured bacteria of the class *Actinobacteria* have been designated potential members of the *Acidimicrobiia* and *Acidimicrobiales* through analysis of their cloned 16S rRNA genes. Three genera have been described (*Acidimicrobium*, *Ferrimicrobium*, and *Ferrithrix*), which contain species from acidic mine waters or geothermal sites. The rRNA gene sequences of these species are relatively closely related among more divergent sequences found in some of the uncultured *Acidimicrobiia*. Another acidophilic, iron-oxidizing species, related to *Acidimicrobium ferrooxidans* has been isolated and will require placement in a new genus ("*Acidithiomicrobium*" sp.). These genera share their acidophilic phenotype (optimum growth at about pH 2) and a capacity for ferrous iron oxidation. In contrast, the type species of the genus *Iamia* (*Iamia majanohamensis*) is a neutrophile (optimum growth at pH 7; pH range 6–9). It was isolated from the epidermis of sea cucumber and is unlikely to oxidize ferrous iron. The 16S rRNA gene sequence of *Iamia majanohamensis* indicates a phylogenetic placement between the acidophiles of the *Acidimicrobiales* and representatives of the relatively closely related orders of the *Actinobacteria* (sequences from the type species of the type genera of the type families of the *Rubrobacteriales*, *Bifidobacteriales*, and *Coriobacteriales* were used in phylogenetic tree construction; Figure 412). Further consideration of the content, limits, and possible subdivision of the *Acidimicrobiales*, and any concurrence of these aspects with phenotype, will be facilitated by isolation and characterization of some of the large number of uncultured "*Acidimicrobiia*" that are phylogenetically peripherally related to the classified acidophiles of the order.

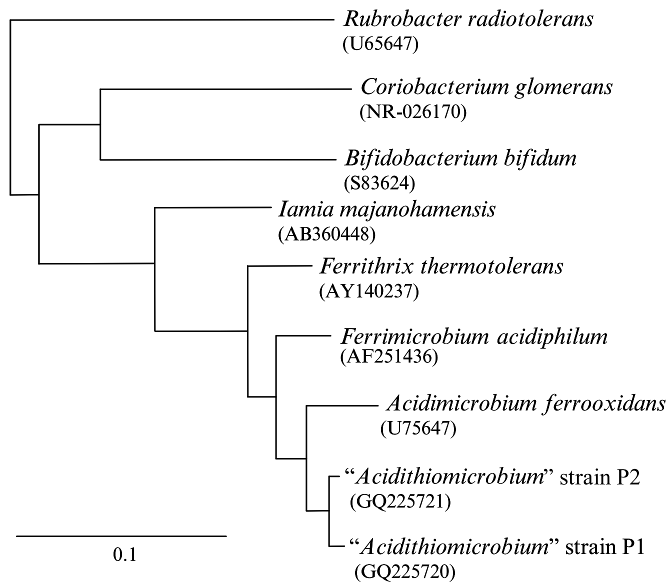

FIGURE 412. Phylogenetic relationships of members of the *Acidimicrobiales* and the most closely related orders of the *Actinobacteria*. Maximum-likelihood evolutionary tree of 16S rRNA gene sequences (GenBank accession nos in parentheses) from type species of the type genera of the orders *Rubrobacteriales* (the outgroup), *Bifidobacteriales* and *Coriobacteriales*, from the type species of the type genus of the family *Iamia*, and from the cultured, ferrous iron-oxidizing actinobacteria of the *Acidimicrobiales*. Bar = 0.1 substitutions per site. Bootstrap values from 100 replicates are shown.

Family I. **Acidimicrobiaceae** Stackebrandt, Rainey and Ward-Rainey 1997, 483[VP]

Paul R. Norris

A.ci.di.mi.cro.bi.a.ce′a.e. N.L. neut. n. *Acidimicrobium* type genus of the family; suff. *-aceae* ending to denote a family; N.L. fem. pl. n. *Acidimicrobiaceae* the *Acidimicrobium* family.

Small rods, sometimes occur as filaments. Acidophilic, mesophilic, or moderately thermophilic, with the capacity for ferrous iron oxidation. All species are capable of heterotrophic growth. Some species are also autotrophic. The genera of this family (*Acidimicrobium*, *Ferrimicrobium*, and *Ferrithrix*) have single species representatives that, along with the unclassified "*Acidithiomicrobium* sp.", have the pattern of 16S rRNA signatures proposed for the class *Acidimicrobiia*.

Type genus: **Acidimicrobium** Clark and Norris 1996, 1189[VP] (Effective publication: Clark and Norris 1996, 790.).

Genus I. **Acidimicrobium** Clark and Norris 1996, 1189[VP] (Effective publication: Clark and Norris 1996, 790.)

A.ci.di.mi.cro′bi.um. N.L. neut. n. *acidum* (from L. adj. *acidus* sour) an acid; Gr. adj. *mikros* small; Gr. masc. n. *bios* life; N.L. neut. n. *microbium*, a microbe; N.L. neut. n. *Acidimicrobium* referring to a small bacterium from acidic environments.

Thermotolerant or **moderately thermophilic, acidophilic bacterium**. **Small, rod-shaped cells**, which may be in filaments of variable length. **Optimum growth occurs at 45–50°C** and approximately pH 2. Heterotrophic growth occurs on yeast extract, during which cells are motile. **Autotrophic growth occurs on ferrous iron. Most rapid growth is observed aerobically with ferrous iron and yeast extract.** Found in warm, acidic, mineral sulfide-rich environments.

DNA G+C content (mol%): 67–68 (T_m and HPLC).

Type species: **Acidimicrobium ferrooxidans** Clark and Norris 1996, 1189[VP] (Effective publication: Clark and Norris 1996, 790.).

Further descriptive information

The phylogenetic relationships of *Acidimicrobium* and related species are illustrated in Figure 412. The rod-shaped cells (0.35–0.4 × 1–1.5 µm) are sometimes found in long filaments, depending on the strain and growth conditions (Figure 413). The major fatty acids of total cell hydrolysates are $C_{16:0}$ iso (83%) and $C_{17:0}$ anteiso (8%) and the major menaquinone is MK-9(H_8) (Kurahashi et al., 2009).

Autotrophic growth occurs with ferrous iron as substrate in the presence of low concentrations of reduced sulfur compounds such as tetrathionate, which might provide a source of reduced sulfur for biosynthesis. Heterotrophic growth occurs with yeast extract (0.02%, w/v). Most rapid growth occurs in the presence of ferrous iron and yeast extract. Pyrite is rapidly oxidized during growth in the presence of yeast extract, but growth on elemental sulfur has not been described. Anaerobically, reduction of ferric iron occurs in the presence of organic substrates (yeast extract and glycerol).

Found in warm, acidic, iron-, sulfur- or mineral-sulfide-rich environments, including industrial commercial copper leach dumps, coal mine drainage, and natural geothermal springs.

Enrichment and isolation procedures

The type strain of the type species (*Acidimicrobium ferrooxidans* strain ICP[T]) was isolated from enrichment cultures grown in a mineral salts medium which contained (g/l): $MgSO_4 \cdot 7H_2O$ (0.4), $(NH_4)_2SO_4$ (0.2), K_2HPO_4 (0.1), $FeSO_4 \cdot 7H_2O$ (13.9), and yeast extract (0.2). The phosphate concentration was reduced (K_2HPO_4, 0.01 g/l) in medium solidified with phytagel (0.4%, w/v) for single colony isolation.

Maintenance procedures

Cultures can be maintained for several months at room temperature without shaking in medium (initially pH 2) containing pyrite (50–100 µm diameter particle size) and yeast extract (0.02%, w/v). The type strain can also be maintained vacuum dried and at −70°C in the presence of 7% (v/v) DMSO (Hallberg and Johnson, 2007).

Differentiation of the genus *Acidimicrobium* from other genera

The DNA G+C content and 16S rRNA gene sequence differentiate bacteria of the *Acidimicrobium* and related genera of iron-oxidizing actinobacteria (Table 305, Figure 412), whereas most other features are common to more than one genus. The single species representatives of the genera *Acidimicrobium*, *Ferrimicrobium*, and *Ferrithrix* (and the unclassified "*Acidithiomicrobium*" species) have the pattern of 16S rRNA signatures proposed for the *Acidimicrobiia*, *Acidimicrobiales*, and *Acidimicrobiaceae*, with nucleotides at positions 242:284 (U–G), 291:309 (U–A), 316:337 (C–G), 819 (U), 952:1229 (C–G), and 1115:1185 (U–G).

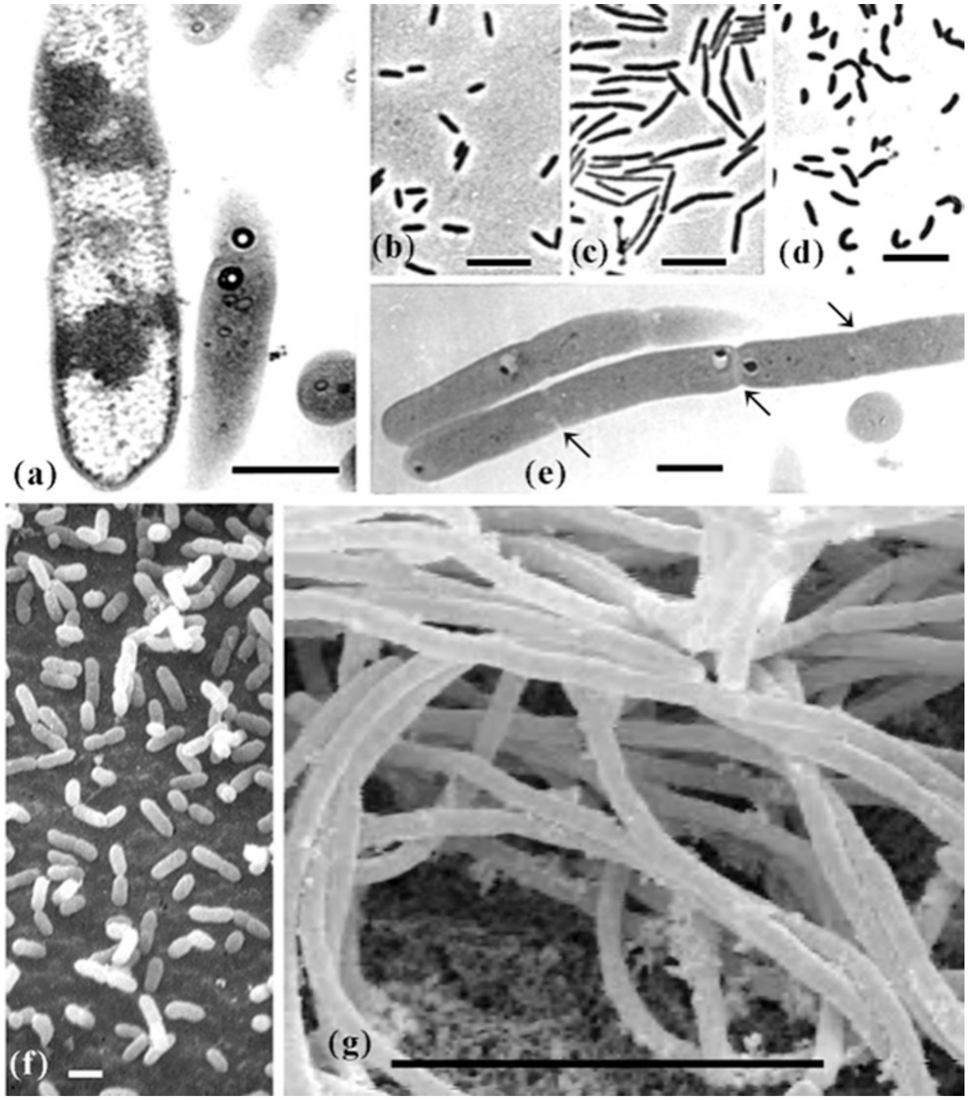

FIGURE 413. Morphology of ferrous-iron-oxidizing actinobacteria. (a) Electron micrograph of thin sections of a mixed culture of iron-oxidizing moderate thermophiles from which the type strain of *Acidimicrobium ferrooxidans* (strain ICP[T]) was isolated, showing small *Acidimicrobium*-like bacteria with a larger *Sulfobacillus* sp. (bar = 0.5 µm**).** Light microscopy of the type strain of *Acidimicrobium ferrooxidans* grown (b) autotrophically on ferrous iron, (c) on ferrous iron and yeast extract, and (d) heterotrophically on yeast extract (bars = 5 µm). List of species of the genus *Acidimicrobium*

1. **Acidimicrobium ferrooxidans** Clark and Norris 1996, 1189[VP] (Effective publication: Clark and Norris 1996, 790.)

fer.ro.o′xi.dans. L. n. *ferrum* iron; N.L. v. *oxido* to oxidize; N.L. part. adj. *ferrooxidans* iron-oxidizing.

Cells are small and rod-shaped and may be in filaments of variable length. In contrast to the type strain, ICP[T], strain TH3 generally grows in filaments (Figure 413).

The optimum temperature for growth is about 48°C, with good activity maintained at 30°C and the maximum temperature for growth is about 57°C. Autotrophic growth on ferrous iron is weak compared to that of most autotrophic iron-oxidizing acidophiles. Heterotrophic growth occurs with yeast extract. Most rapid growth occurs in the presence of ferrous iron and yeast extract, where iron oxidation rapidly goes to completion. In the presence of yeast extract, pyrite is extensively oxidized during growth. In contrast, only weak acidification of the medium has been observed during growth with yeast extract and sulfur, and a capacity for sulfur oxidation has not been established.

Source: the type strain, ICP[T], was isolated from a pyrite enrichment culture established with a sample from an Icelandic geothermal site. Previously, strain TH3 of the same species was isolated from a copper mine leach dump in the USA (Norris and Barr, 1985). The TH3 designation was used previously for the original isolate of the species which came from the same source, but was not retained in culture (Brierley, 1978).

DNA G+C content (mol%): 67–68 (T_m and HPLC).

Type strain: ICP, DSM 10331.

Sequence accession no. (16S rRNA gene): U75647.

Genus II. **Ferrimicrobium** Johnson, Bacelar-Nicolau, Okibe, Thomas and Hallberg 2009, 1087[VP]

Paul R. Norris

Fer.ri.mi.cro′bi.um. L. n. *ferrum* iron; N.L. neut. n. *microbium* microbe; N.L. neut. n. *Ferrimicrobium* iron microbe, referring to its capacity for ferrous iron oxidation.

Motile rods, Gram-stain-negative. **Acidophilic**, mesophilic, and obligately heterotrophic. Capable of **oxidation of ferrous iron** and pyrite, and reduction of ferric iron. Grows with yeast extract or a limited range of organic compounds.

DNA G+C content (mol%): 55 (T_m).

Type species: **Ferrimicrobium acidiphilum** Johnson, Bacelar-Nicolau, Okibe, Thomas and Hallberg 2009, 1087[VP].

Further descriptive information

All information, including 16S rRNA phylogeny (Figure 412), pertains to the type strain of *Ferrimicrobium acidiphilum*, T23[T] (Johnson et al., 2009).

Colonies of the type species (strain T23[T]) display a "fried egg"-like morphology on solid medium (Johnson et al., 2009). Cells are rod-shaped and motile, with chains of three to five cells common during exponential growth. *meso*-Diaminopimelic acid is present in the peptidoglycan, which is of type A1γ. The major fatty acids are $C_{16:0}$ iso and $C_{14:0}$ iso (acetone extraction of whole-cell lysate). The dominant menaquinone is MK-8(H_{10}).

Optimum growth is observed at 35°C (no growth at 45°C) and pH 2.0 (minimum pH 1.4). Heterotrophic growth occurs on yeast extract and a limited range of defined organic substrates, including glycerol, citric acid, and glutamic acid.

16S rRNA gene sequences almost identical to that of *Ferrimicrobium acidiphilum* have been cloned from DNA extracted from various acidic mine waters or soils worldwide, including from the UK, the USA, Spain, and China.

Enrichment and isolation procedures

Ferrimicrobium acidiphilum T23[T] was isolated from pyrite enrichment cultures inoculated with mine water from the abandoned Cae Coch sulfur mine, North Wales, UK, by plating on a ferrous iron-containing overlay solid medium (Johnson and Hallberg, 2007).

Maintenance procedures

Ferrimicrobium acidiphilum T23[T] is routinely subcultured in liquid media containing 10 mM ferrous sulfate and 0.02% (w/v) yeast extract at pH 2.0 and 30°C. Cultures can be maintained for several months at room temperature without shaking in medium (initially pH 2) containing pyrite (50–100 µm particle size diameter) and yeast extract (0.02%, w/v). The type strain can also be maintained at −70°C in the presence of 7% (v/v) DMSO (Hallberg and Johnson, 2007).

Differentiation of the genus *Ferrimicrobium* from other genera

Among the single species-containing genera of iron-oxidizing actinobacteria, *Ferrimicrobium acidiphilum* is the only mesophile and can also be distinguished by its DNA composition and 16S rRNA gene sequence (Table 305).

List of species of the genus *Ferrimicrobium*

1. **Ferrimicrobium acidiphilum** Johnson, Bacelar-Nicolau, Okibe, Thomas and Hallberg 2009, 1087[VP]

a.ci.di′phi.lum. N.L. neut. n. *acidum* (from L. adj. *acidus* sour) an acid; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. neut. adj. *acidiphilum* acid-loving.

Cells are rod-shaped, 1–3 µm in length and 0.5 µm in diameter, and motile. Gram-stain-negative. Forms gelatinous colonies of approximately 1–3 mm diameter and with ferric iron deposits in the center on ferrous iron overlay plates. Mesophilic, optimum growth is at 35°C (maximum 37°C), and acidophilic, optimum growth is at pH 2 (minimum pH 1.4). Obligately heterotrophic with growth on yeast extract, glycerol, citric acid, and glutamic acid. Capable of oxidation of ferrous iron and pyrite, and, in the presence of glycerol, reduction of ferric iron. *meso*-Diaminopimelic acid is present in the peptidoglycan, which is of type A1γ. The major fatty acids are $C_{16:0}$ iso (64%), $C_{14:0}$ iso (11%), $C_{17:1}$ ω6*c* (5.97%), $C_{15:0}$ anteiso (5.14%), $C_{15:0}$ iso (5.03%), $C_{17:0}$ anteiso (3.18%), $C_{16:1}$ iso H (2.49%), and $C_{14:0}$ iso 3-OH (1.20%). The dominant menaquinone is MK-8(H_{10}), with minor amounts of MK-8 and MK-8(H_{10}) containing one or two methyl groups (Johnson et al., 2009).

Source: found in acidic iron-rich environments associated with the oxidation of sulfide minerals, such as acid mine drainage waters.

DNA G+C content (mol%): 55 (T_m).

Type strain: T23, DSM 19497, ATCC BAA-1647.

Sequence accession no. (16S rRNA gene): AF251436.

Genus III. **Ferrithrix** Johnson, Bacelar-Nicolau, Okibe, Thomas and Hallberg 2009, 1088[VP]

Paul R. Norris

Fer.ri.thr′ix. L. n. *ferrum* iron; Gr. fem. n. *thrix* hair, thread; N.L. fem. n. *Ferrithrix* iron thread, referring to filamentous nature and capacity for ferrous iron oxidation.

Grows as filaments (occasionally as single rods). Gram-stain-negative. **Acidophilic, thermotolerant**, or moderately thermophilic, with optimum growth at 43°C. **Obligately heterotrophic**. Grows on yeast extract, glycerol, or ethanol. Capable of **ferrous iron oxidation** and ferric iron reduction. Unknown growth factor(s) from yeast extract is (are) required for growth.

DNA G+C content (mol%): 50 (T_m).

Type species: **Ferrithrix thermotolerans** Johnson, Bacelar-Nicolau, Okibe, Thomas and Hallberg 2009, 1088[VP].

Further descriptive information

All information (see list of species) relates to the type strain (Y005[T]) of the single species (Johnson et al., 2009). Its phylogenetic relationship to other acidophilic, iron-oxidizing actinobacteria is illustrated in Figure 412.

Ferrithrix thermotolerans has not yet been isolated from outside of geothermal regions of Yellowstone National Park, USA, but closely related 16S rRNA gene sequences have been cloned from acid mine drainage in the UK and Spain.

Enrichment and isolation procedures

Ferrithrix thermotolerans was isolated from overlay solid medium containing ferrous iron that was streaked with a sample of a ferrous iron/yeast extract enrichment culture established with an acidic sample from the Beryl Spring/Gibbon River area of Yellowstone National Park (Johnson et al., 2003).

Maintenance procedures

Cultures can be maintained for at least 1 year at room temperature in medium (initially pH 2) containing pyrite (50–100 µm diameter particle size) and yeast extract (0.02%, w/v). The type strain can also be maintained at −70°C in the presence of 7% (v/v) DMSO (Hallberg and Johnson, 2007).

Differentiation of the genus *Ferrithrix* from other genera

Among the single species-containing genera of iron-oxidizing actinobacteria, *Ferrithrix thermotolerans* can be distinguished by its optimum growth temperature, which is between that of the mesophilic *Ferrimicrobium acidiphilum* and the moderately thermophilic *Acidimicrobium ferrooxidans*, and by its DNA composition and 16S rRNA gene sequence (Table 305).

List of species of the genus *Ferrithrix*

1. **Ferrithrix thermotolerans** Johnson, Bacelar-Nicolau, Okibe, Thomas and Hallberg 2009, 1088[VP]

ther.mo.to′le.rans. Gr. n. *thermê* heat; L. part. adj. *tolerans* tolerating; N.L. part. adj. *thermotolerans* heat-tolerating, able to tolerate high temperatures.

Grows as filaments (Figure 413), which form visible flocs of approximately 1–3 mm diameter, and occasionally as nonmotile, rod-shaped cells of 3–4 × 0.5 µm. Gram-stain-negative. Colonies are small (1–2 mm in diameter), rhizoidal, and iron-encrusted on ferrous iron, ferrous iron/tetrathionate

solid overlay media. The peptidoglycan type is A1γ. The major fatty acid is $C_{16:0}$ iso, with other fatty acids present in minor amounts. Optimal growth is at 43°C (maximum 50°C). Acidophilic, with optimal growth at pH 1.8 (minimum pH 1.6). Obligately heterotrophic, capable of growth with yeast extract, glycerol, and ethanol. An unknown growth factor(s) supplied by yeast extract is (are) required for growth. Also able to oxidize ferrous iron and reduce ferric iron.

Source: found in geothermal springs.

DNA G+C content (mol%): 50 (T_m).

Type strain: Y005, DSM 19514, ATCC BAA-1645.

Sequence accession no. (16S rRNA gene): AY140237.

Other bacteria

An *Acidimicrobium*-like bacterium, which was found in a pyrite-enrichment mixed culture with *Acidimicrobium ferrooxidans*, was initially referred to as "*Acidimicrobium*" species 2 (Cleaver et al., 2007). This bacterium was subsequently obtained in pure culture, but it has not yet been officially named. A closely related bacterium was isolated from an acidic, geothermal soil in Greece. These moderately thermophilic acidophiles have been described as "*Acidithiomicrobium*" strains P1 and P2, respectively (Norris et al., 2011; 16S rRNA gene sequence accession nos GQ225720 and GQ225721, respectively). They are noted here as close relatives of *Acidimicrobium ferrooxidans* and as species which increase the metabolic diversity of this family of actinobacteria. They grow strongly autotrophically on ferrous iron or pyrite in contrast to *Acidimicrobium ferrooxidans* and grow strongly autotrophically with elemental sulfur as the sole substrate (Davis-Belmar and Norris, 2009). They grow at slightly higher temperatures than *Acidimicrobium ferrooxidans* (Table 305). These features and their phylogenetic relationship to the other iron-oxidizing actinobacteria are noted (Table 305, Figure 412).

The family *Iamiaceae* was created for the type species *Iamia majanohamensis* in recognition of the evolutionary distance of its 16S rRNA gene sequence from that of *Acidimicrobium ferrooxidans*, the type species of the type genus of the *Acidimicrobiaceae*.

The pattern of 16S rRNA gene sequence signature nucleotides for the family consists of 408:434 (G–C), 722:733 (G–G), 1118:1155 (U–A), 443:491 (U–A), 1165:1171 (G–C), and 1263:1272 (A–U).

Type genus: **Iamia** Kurahashi, Fukunaga, Sakiyama, Harayama and Yokota 2009, 871[VP].

Genus I. **Iamia** Kurahashi, Fukunaga, Sakiyama, Harayama and Yokota 2009, 871^{VP}

Paul R. Norris

I.a′mi.a. N.L. fem. n. *Iamia* arbitrary name formed from the acronym of the Institute of Applied Microbiology at the University of Tokyo, which has made significant contributions to microbiology.

Gram-stain-positive rods. Aerobic. Oxidase- and catalase-positive. Mesophilic. The predominant menaquinone is MK-9(H_6). The major whole-cell fatty acids are $C_{17:0}$, $C_{17:1}$ ω8*c*, $C_{15:0}$, and $C_{16:0}$. Isolated from the epidermis of a sea cucumber and grown on marine agar.

DNA G+C content (mol%): 74.

Type species: **Iamia majanohamensis** Kurahashi, Fukunaga, Sakiyama, Harayama and Yokota 2009, 871^{VP}.

Further descriptive information

The phylogenetic relationship of the single species of *Iamia* to those of the *Acidimicrobiaceae*, the other family of the *Acidimicrobiales*, is illustrated in Figure 412. Further descriptive information is as for the single species, *Iamia majanohamensis* (Kurahashi et al., 2009).

Enrichment and isolation procedures

Iamia majanohamensis was obtained from the abdominal epidermis of a sea cucumber, *Holothuria edulis*, which was collected off the coast of Aka Island, Okinawa prefecture, Japan (Kurahashi and Yokota, 2004). Cultures were maintained routinely on marine agar at 25°C.

List of species of the genus *Iamia*

1. **Iamia majanohamensis** Kurahashi, Fukunaga, Sakiyama, Harayama and Yokota 2009, 871^{VP}

ma.ja.no.ha.men′sis. N.L. fem. adj. *majanohamensis* pertaining to Majanohama, the site on the coast of Aka Island, Japan, where the type strain was isolated.

Gram-stain-positive rods, 1.2–1.7 by 0.3–0.5 µm. Aerobic. Oxidase- and catalase-positive. Colonies on marine agar (which contains peptone and yeast extract) are small, white, circular, convex, smooth, shiny, and 0.2–0.3 mm in diameter after 3 weeks incubation at 30°C. Optimal growth temperature is 28–30°C. No growth occurs below 10°C or above 45°C. Hydrolysis of gelatin is observed. Positive for arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, production of acetoin and gelatinase, and reduction of nitrate to N_2, but negative for β-galactosidase, urease, tryptophan deaminase, utilization of citrate, production of H_2S and indole, and assimilation of amygdalin, arabinose, D-glucose, inositol, D-mannose, melibiose, rhamnose, sucrose, and sorbitol.

Source: the type strain was isolated from the ventral epidermis of the sea cucumber *Holothuria edulis* at Aka Island, Okinawa, Japan.

DNA G+C content (mol%): 74.4 (HPLC).

Type strain: F12, NBRC 102561, DSM 19957.

Sequence accession no. (16S rRNA gene): AB360448.

The pattern of 16S rDNA/rRNA signature nucleotides (base positions relative to *Escherichia coli*) of members of the family consists of 113:314 (C–G), 294:303 (G–C), 295:302 (U–A), 407:435 (C–G), 613:627 (G–C), 670:736 (G–C), 771:808 (U–A), 772:807 (A–U), 823:877 (A–U), 941:1342 (A–U), 950:1231 (U–G), 1120:1153 (G–C), 1148 (C), 1165:1171 (C–G), 1242:1295 (G–C), 1313:1324 (G–C), 1321 (C), 1410:1490 (A–U), 1415:1485 (C–G) and 1416:1484 (C–G). The family contains the genera *Coriobacterium*, *Atopobium*, *Collinsella*, *Cryptobacterium*, *Denitrobacterium*, *Eggerthella*, *Olsenella*, and *Slackia*. The genera were circumscribed on the basis of phylogenetic analysis of the 16S rDNA/rRNA gene sequences.

Rod-shaped or coccoid cells occur singly, in pairs or as rods. Spores and flagella are absent. Gram-stain-positive. Strictly or facultatively anaerobic growth. Sugars may or may not be fermented. The family *Coriobacteriaceae* was circumscribed on the basis of phylogenetic analysis of the 16S rDNA/rRNA gene sequences (Figure 414).

Type genus: **Coriobacterium** Haas and König 1988, 383[VP].

Genus I. **Coriobacterium** Haas and König 1988, 383[VP]

Helmut König

Co.ri.o.bac.ter′i.um. Gr. fem. n. *koris* bug; Gr. neut. n. *bakterion* a small rod; N.L. neut. n. *Coriobacterium*, rodlet associated with bugs.

The cells form chains of **pear-shaped** to irregularly shaped rods. The bacteria are **obligately anaerobic**. The cells stain **Gram-positive**. Spores and **flagella are absent**. Under strictly anaerobic conditions, the **fermentation products** of glucose are **acetic acid**, **L-lactic acid**, and **ethanol**. The **peptidoglycan** belongs to the **Lys–Asp type** (A4α). The bacteria occur in the **intestinal tracts** of insects.

DNA G+C content (mol%): 60–61.

Type species: **Coriobacterium glomerans** Haas and König 1988, 383[VP].

Further descriptive information

The fermentation products from glucose are L-lactic acid, acetic acid, and ethanol under strict anaerobic conditions with N_2/CO_2 as gas phase (using the culture technique of Balch et al. (1979). Under certain conditions in TPY medium (Scardovi, 1981), CO_2 and H_2 are also produced.

Enrichment and isolation procedures

A Gram-stain-positive anaerobic bacterium was regularly found in great numbers in histological sections and anaerobic cultures of the third bulbous mid-gut portion of the red soldier ant *Pyrrhocoris apterus* (L.). It formed long chains of irregular pear-shaped cells with large spherical involutions. All histological sections showed bundles of Gram-stain-positive chain-forming bacteria attached to the epithelium of the intestine at the beginning of the third bulbous portion of the mid-gut. The chains could reach more than 150 μm into the lumen of the gut.

Flattened, dry-looking colonies of chain-forming rod-like bacteria, with filamentous and irregular edges, could be detected when the gut contents were incubated anaerobically on blood-agar or supplemented Schaedler agar plates after 5–10 d at an incubation temperature of 25–37°C. The bacteria were further purified on TPY agar plates. The colonies consisted of long filaments, bent into hairpins, curls, and loops. In fluid TPY medium, bacteria formed a flocculent, woolly sediment with a clear supernatant.

Maintenance procedures

The bacteria can be maintained on TPY agar plates at 37°C. For longer periods, cultures can be stored in liquid nitrogen in the presence of 10% glycerol.

Differentiation of the genus *Coriobacterium* from other genera

Coriobacterium glomarans, the only species of this genus, is distinguished from members of the genus *Lactobacillus* by its higher G+C content (strain PW2[T], 60–61 mol%; *Lactobacillus*, 32–53 mol%) and by the molar ratio of the fermentation products.

Coriobacterium glomarans shares some characteristics with the genus *Bifidobacterium* (e.g. G+C content of the DNA 55–67 mol%) and it possesses the type 6 murein of this genus (Scardovi, 1981). Based on its ability to ferment carbohydrates, it does not correspond to any species in this group. It differs from the genus *Bifidobacterium* by its lack of a positive test for fructose-6-phosphate phosphoketolase and by production of hydrogen. The high amount of ethanol produced cannot be explained by the hexose fermentation pathway in bifidobacteria.

Strain PW2[T] is distinguished from *Eubacterium* by the G+C mol% content of its DNA (*Eubacterium*, 30–55 mol%), usually by its fermentation products, and by its murein composition. Several members of the genus *Eubacterium* produce hydrogen, and acetic and lactic acids as the sole major acid products, but among

these species, where the G+C content of the DNA is known, it is about 45 mol%; also, those species of *Eubacterium* that have been investigated possess the quite different type B murein.

The genus *Lachnospira* has been defined as containing curved-to-helical subterminally flagellated rods.

Coriobacterium glomarans is immotile, and flagella have not been observed by electron microscopy. *Lachnospira* but not *Coriobacterium glomarans* forms formic acid from glucose.

Taxonomic comments

Coriobacterium glomerans Haas and König 1988, 383^{VP} is the only species so far described in the genus *Coriobacterium*, but other strains/clones have been described (strain CCUG 33917, AJ131149; strain CCUG 33918, AJ131150; strain EKSO3, AJ245921; strain 3WC8.1, AJ586811; strain SG1214, AY669285; clone CC1015, AY669270).

List of species of the genus *Coriobacterium*

1. **Coriobacterium glomerans** Haas and König 1988, 383^{VP}

glo′me.rans. L. part. adj. *glomerans* agglomerating.

The cells form flocculent, wooly sediments with a clear supernatant in fluid media. They are regular to pear-shaped, forming cell chains under strictly anaerobic conditions (using the culture technique of Balch et al. (1979). They form irregularly shaped rods in older cultures or after culture in the GasPak Anaerobic System. The bacteria are strictly anaerobic. The cells are Gram-stain-positive (Kopeloff modification of the Gram stain).

The cells have an electron-dense Gram-stain-positive cell wall, 40 nm wide. The peptidoglycan belongs to the Lys–Asp type (A4α). The peptide subunit is composed of Asp, Glu, Gly, Ala, and Lys in a molar ratio of 0.91:1.00:0.45:1.96:1.01.

The length of the cells varies (0.44–1.80 μm). Spherical involution forms with a diameter of up to 198 μm are common. The bacteria form chains more than 150 μm long (Figure 415).

The colonies consist of long filamentous chain-forming bacteria, bent into hairpins, curls, and loops. The colony size is about 0.6 mm. The organisms grow on blood agar (Columbia agar base [BBL]), supplemented Schaedler agar (BBL), and TPY agar at 25°C and 30°C. When grown in TPY medium, the bacteria produce acetic acid, L-lactic acid, and ethanol from glucose in a molar ratio of 1.16:1.00:0.95. CO_2 and H_2 are also produced. D-Lactic acid, formic acid, volatile short-chain alcohols, or other volatile fatty acids are not formed. Under more stringent anaerobic conditions with N_2–CO_2 (80:20) as the gas phase, but lacking H_2, the molar ratio of acetic acid to L-lactic acid to ethanol is 1.20:1.00:0.23. This indicates that in the presence of the higher concentrations of molecular hydrogen (produced by the commonly used GasPack anaerobic system) strain PW2T forms increased amounts of ethanol.

The cells ferment L-arabinose, cellobiose, glucose, maltose, mannitol, melibiose, raffinose, mannose, ribose, salicin, sucrose, and D-xylose. Inositol, inulin, lactose, melibiose, raffinose, and starch are not fermented.

FIGURE 415. Electron micrograph of *Coriobacterium glomerans* strain PW2. Platinum shadowing of a cell chain showing irregular cells.

Source: the third bulbous midgut portion of all stages of the red soldier ant (*Pyrrhocoris apterus*; Heteroptera: Pyrrhocoridae), except the egg stage. The filamentous cell chains are attached to the epithelia of the intestines.

DNA G+C content (mol%): ca. 61 (T_m and nucleotide analysis)

Type strain: PW2, ATCC 49209, DSM 20642, JCM 10262.

DNA G+C content (mol%): X79048 (EMBL).

Genus II. **Atopobium** Collins and Wallbanks 1993, 188^{VP} (Effective publication: Wallbanks and Collins 1992, 239.)

Paul A. Lawson

A.to.po′bi.um. Gr. adj. *atopos* having no place, strange; Gr. neut. part. used as a noun *bion* living thing; N.L. neut. n. *Atopobium* strange living thing.

Cells consist of short rods, often with central swellings, or small cocci that may appear to be elliptical. They occur singly, in pairs, and in short chains. Gram-stain-positive, does not form spores, and is nonmotile. **Obligately or facultatively anaerobic and catalase-negative.** Nitrate is not reduced. **The major fermentation products from glucose are lactic acid together with acetic and formic acids; trace amounts of succinic acid may be formed.** Hydrogen is not produced. Growth is stimulated by

DNA G+C content (mol%): 35–46 (T_m).

Type species: **Atopobium minutus** (Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937) Collins and Wallbanks 1993, 188[VP] (Effective publication: Wallbanks and Collins 1992, 239.) (*Lactobacillus minutus* Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937; Moore and Holdeman 1972, 63[AL] emend. Olsen, Johnson, Moore and Moore 1991).

Further descriptive information

In addition to being Gram-stain-positive and non-sporeforming rods to cocci, cells may contain central swellings. A variety of peptidoglycan types are evident, *Atopobium minutus* contains L-Orn–L-Ser–D-Glu (A4β), *Atopobium parvulum* L-Lys–D-Asp (A4α), and *Atopobium fossor* and *Atopobium rimae* L-Ala–D-Glu–LL-Dpm-Gly (A3γ). The cell-wall structure of *Atopobium vaginae* has not been determined. *Atopobium* species possess some unifying traits, but can be distinguished by a number of tests that include carbohydrate fermentation patterns, the presence or absence of metabolic enzymes, and the end products of glucose metabolism (see Table 306).

Atopobium spp. have been isolated from a number of human and animal sources. *Atopobium parulum* and *Atopobium rimae* were originally isolated from the human gingival crevice and *Atopobium vaginae* from the human vagina. Numerous studies employing both culture and culture-independent methods based on the sequencing of 16S rRNA genes have shown that *Atopobium* and other members of the family *Coriobacteriaceae* contribute towards the normal flora of the gastrointestinal tract and are readily recovered from human feces (Harmsen et al., 2000; Holdeman et al., 1976). Harmsen and colleagues developed a specific probe to two clusters that include *Coriobacterium* and *Collinsella* (S-*-Cor-0653-a-A18 (COR653) 5′ CCTCCC(/C) TACCGGACCC) and *Atopobium* S-*-Ato-0291-a-A-17 (ATO291) 5′ GGTCGGTCTCTCAACCC) which also includes the *Coriobacterium* group. These studies suggested that the diversity of *Atopobium* strains present in feces appeared to increase with the age of the individual. Although considered to be part of the normal flora of the GI tract, *Atopobium* may under particular conditions act as an opportunistic pathogen and contribute towards disease processes. *Atopobium rimae* and *Atopobium parvulum*, for example, have been identified as agents of chronic periodontitis (Kumar et al., 2005; Olsen et al., 1991).

Kumar et al. (2005) used a quantitative 16S clonal analysis to investigate biofilms associated with chronic periodontitis and periodontal health. Their data demonstrated that in addition to a number of other genera, *Atopobium* phylotypes were elevated in disease tissue. Furthermore, Angelakis et al. (2009)

reported an unusual case of human bacteremia caused by *Atopobium rimae* that was directly responsible for the septicemia.

Perhaps the most compelling evidence for the association of *Atopobium* with disease comes from investigations involving *Atopobium vaginae* with bacterial vaginosis (BV). Studies employing specific PCR primers towards *Atopobium* suggest that as many as 70% of women with BV harbor *Atopobium vaginae* and that postmenopausal women are particularly susceptible to BV (Burton et al., 2004). Although the exact etiology is still not clear, a possible explanation is that the available fermentable carbohydrate glycogen from vaginal epithelial cells decreases during the onset of menopause (Boskey et al., 1999; Burton et al., 2004; Cauci et al., 2002) promoting the use of other metabolic sources (i.e. proteins) for energy.

Atopobium fossor, the only non-human species of this genus, was originally isolated from horses; it is often recovered as a common component of the bacterial mixed-culture of the pharynx in addition to tooth root abscesses. Moreover, in a recent study of the lower respiratory tract of horses diagnosed with pneumonia, Racklyeft and Love (2000) found that 32% of the animals harbored *Atopobium fossor* using culture-based methods. Although they found a number of obligate anaerobes in co-culture, these authors were unable to suggest an association between any particular species and disease.

Isolation procedures

Complex media recommended for anaerobes by the Anaerobe Laboratory at the Virginia Polytechnic Institute (Holdeman et al., 1976) and the Wadsworth-KTL Anaerobe Laboratory Manual (Jousimies-Somer et al., 2002b) are frequently used as basal media. Supplements that include hemin and vitamin K are routinely added along with Tween 80, blood, or serum to enhance growth. There is no enrichment or selective medium for these organisms. *Atopobium minutum*, *Atopobium parvulum*, *Atopobium rimae*, and *Atopobium vaginae* have been recovered from human sources while *Atopobium fossor* has only been isolated from horses.

Maintenance procedures

For short-term storage, *Atopobium* strains can be maintained in chopped meat medium and DSMZ medium 104 PYG-medium (http://www.dsmz.de). For long-term preservation, strains can be maintained in a medium containing 15–20% glycerol at −70°C or lyophilized.

Taxonomic comments

Based on phylogenetic considerations and associated phenotypic features, the novel genus *Atopobium* was proposed by Collins and Wallbanks (1992) to accommodate misclassified *Lactobacillus* and *Streptococcus* species isolated from either human gingival crevices or from abscesses, blood, and wounds (Olsen et al., 1991). The genus originally contained three species, namely *Atopobium minutum*, *Atopobium parvulum*, and *Atopobium rimae*. Kageyama et al. (1999b) transferred *Eubacterium fossor* to the genus *Atopobium* based on phylogenetic and phenotypic evidence. This organism was recovered from the normal flora of the pharynx and from necrotic diseases of tissue surrounding the teeth of horses.

Some initial confusion existed on the precise phylogenetic position of *Atopobium*; the genus was originally described in a study that included organisms with phenotypic traits of lactic acid producing bacteria and other low G+C Gram-stain-positive organisms. However, Stackebrandt and Ludwig (1994) in a more comprehensive study showed that *Atopobium* formed a phyletic line in the *Actinomycetes* line of descent. In addition, Rainey et al. (1994) demonstrated the genera *Atopobium* and *Coriobacterium* were close phylogenetic neighbors which shared a number of phenotypic characteristics; members of these taxa were Gram-stain-positive, nonmotile, and non-spore-forming and gave end products of metabolism that included acetic and lactic acids. The close relationship between the two genera was underpinned in the hierarchic classification system of Stackebrandt et al. (1997) who classified these taxa in the family *Coriobacteriaceae* as they shared 16S rDNA/rRNA signature nucleotides, namely 113:314 (C–G), 294:303 (G–C), 295:302 (U–A), 670:736 (G–C), 771:808 (U–A), 772:807 (A–U), 823:877 (A–U), 941:1342 (A–U),950:1231 (U–G), 1120:1153 (G–C), 1148 (C), 1165:1171 (C–G), 1242:1295 (G–C), 1313:1324 (G–C), and 1410:1490 (A–U). Furthermore, the 16S rDNA loop 1357–1364 of these genera consists of only eight nucleotides while all other taxa in the *Actinomycetes* line of descent contain an additional nucleotide (Rainey et al., 1994).

Differentiation of the genus *Atopobium* from other genera

In addition to differentiation by 16S rRNA gene sequence analysis (Figure 416), *Atopobium* can be readily distinguished from its closest phylogenetic relatives using a combination of biochemical and chemotaxonomic criteria (Table 307).

List of species of the genus *Atopobium*

1. **Atopobium minutum** (Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937) Collins and Wallbanks 1993, 188[VP] (Effective publication: Wallbanks and Collins, 1992, 239.) (*Lactobacillus minutus* Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937; Moore and Holdeman 1972, 63[AL] emend. Olsen, Johnson, Moore and Moore 1991)

mi.nu′tum. L. neut. adj. *minutum* minute, small.

Strictly anaerobic, small, elliptical, nonmotile, Gram-stain-positive rods (approx. 0.6–1.0 × 0.8–3.0 µm) occur singly, in pairs, and in short chains. Colonies on brain heart blood agar are pinpoint to 1 mm in diameter, raised or low convex, entire, translucent to transparent, and buff, gray, light yellow, or white after 5 d of anaerobic incubation at 37°C. Growth is stimulated by 0.02 (v/v) Tween 80 and may be enhanced when 10% (v/v) rabbit serum is added to culture media. Six out of 10 tested strains grew at 45°C. Four out of 11 strains grew in the presence of 6.5% (w/v) NaCl.

The fermentation end products from glucose are lactic acid (0.2–4.5 meq/100 ml of culture; mean for 21 strains, 2.3 meq/100 ml), acetic acid (0–0.9 meq/100 ml; mean for

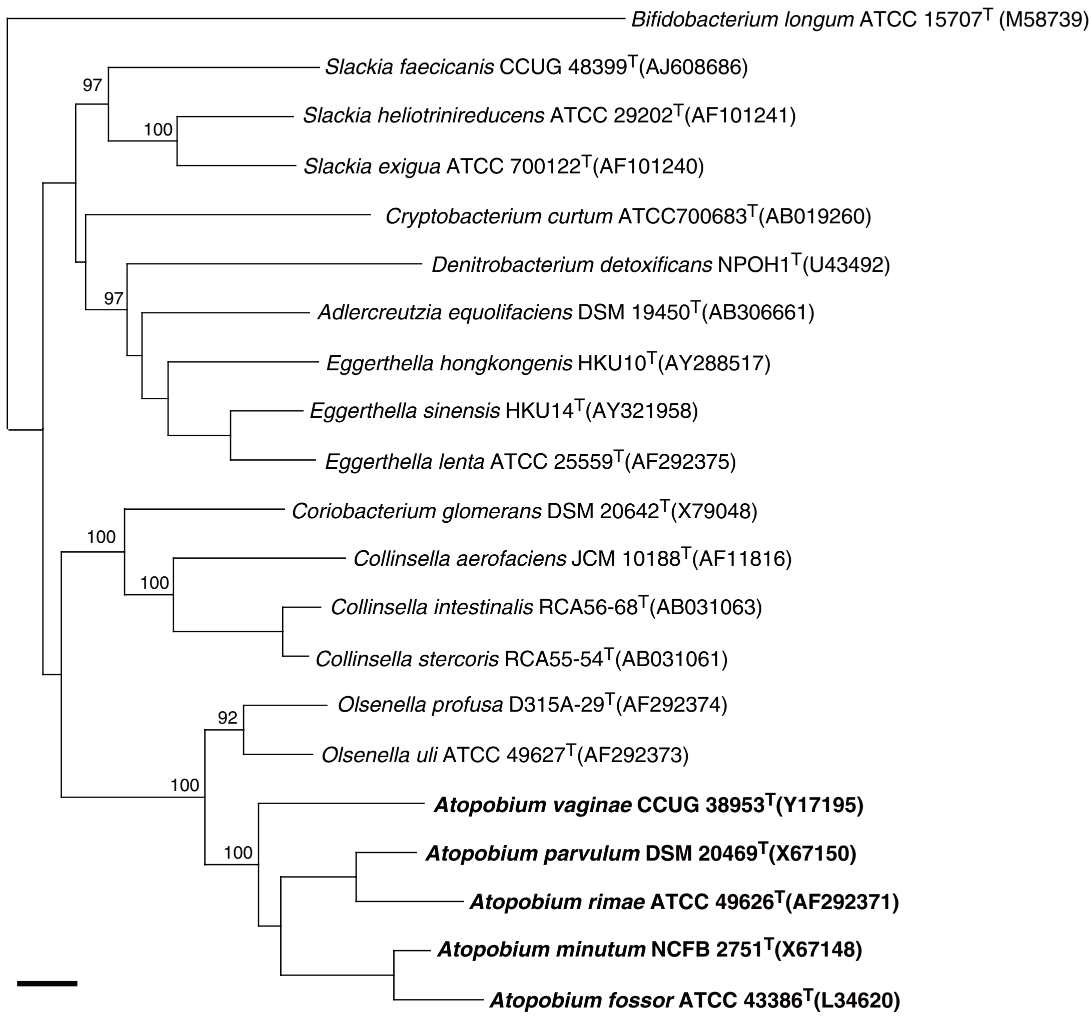

FIGURE 416. Unrooted neighbor-joining tree depicting the estimated phylogenetic relationships of members of the genus *Atopobium* and other members of the family *Coriobacteriaceae. Bifidobacterium longum* was used as the outgroup. The numbers on the branches refer to bootstrap values determined from 1000 replications. Only values about 90% are shown. Bar = 1% sequence divergence.

21 strains, 0.3 meq/100 ml), formic acid (0–0.7 meq/100 ml), and occasionally trace amounts of succinic acid. Little, if any, gas is detected in deep agar cultures. Hydrogen is not produced. The terminal pH range of PYG-Tween 80 broth cultures is 4.5–5.8; the mean terminal pH for 20 tested strains was 5.1.

A few strains (3 out of 27) weakly ferment starch (pH 5.5–5.7), but not amygdalin, erythritol, esculin, glycerol, glycogen, inositol, mannitol, melezitose, melibiose, raffinose, rhamnose, sorbitol, and xylose.

Gelatin is not liquefied, meat is not digested, indole is not produced, and nitrate is not reduced. Reactions are negative for bile-esculin, catalase, DNase, and hippurate hydrolysis.

Susceptibility to antibiotics varies: 1 out of 14 strains were resistant (μg per ml) to chloramphenicol (12), clindamycin (1.6), and erythromycin (3); 2 out of 14 strains were resistant to penicillin G (2U), and 3 out of 14 strains to tetracycline (6).

The major cellular fatty acid derivatives are $C_{18:1}$ *cis*9 fatty acid methyl ester and $C_{18:1}$ dimethylacetyl.

[d]Maruo et al. (2008) found to be $C_{16:0}$ br.

[e]Determined for *Olsenella uli* but not for *Olsenella profuse.*

Obligately anaerobic, Gram-stain-positive, nonmotile cells (0.5–0.9 × 0.3 μm) that vary from coccobacillary to rod-shaped with parallel sides and rounded ends. Polar pili are present. On SBA, colonies are minute after 24 h, enlarging to 1 mm after 48 h when they appear to be set in small pits (0.3 mm deep and 3 mm wide) in the agar. After 4 d, colonies have umbonate to raised centers (1 mm) with either a roughened depressed region or a series of concentric rings radiating outward 1 to 2 mm from the center of colonies. Hemolysis does not occur. Growth in broth is improved by the addition of Tween 80 (0.75%, v/v) or serum (5%, v/v). Dense growth with uniform turbidity and a fine granular deposit is evident when organisms are grown in either prereduced peptone-yeast extract-glucose broth or cooked meat-glucose broth.

Acetic and lactic acids (lactic acid > acetic acid) are the major fermentation products. Gas is not detected in PYT-glucose deep agar cultures, although ammonia, hydrogen, and sulfide are produced.

Acid is formed from mannose but not from adonitol, amygdalin, arabinose, cellobiose erythritol, esculin, fructose, glycogen, inositol, lactose, maltose, mannitol, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose, or xylose.

Most strains, including the type strain, ferment glucose weakly. Acetylmethylcarbinol, catalase, indole, lecithinase, lipase, and urease are not produced nor are esculin, starch, Tween 20, Tween 40, or Tween 80 hydrolyzed. Nitrate is not reduced. There is no reaction in milk and no digestion of gelatin. Bile neither stimulates nor inhibits growth. Cells do not survive heating for 10 min at 80°C.

The organism is susceptible (μg per ml) to ampicillin (4), carbenicillin (100), doxycycline (6), chloramphenicol (12), erythromycin (3), and to penicillin (2U per ml).

Type strain: ATCC 43386, CIP 106638, DSM 15642, JCM 9981, NCTC 11919, VPB 2127.

Sequence accession no. (16S rRNA gene): AB015945, L34620.

3. **Atopobium parvulum** (*ex* Weinberg, Nativelle and Prévot 1937) Collins and Wallbanks 1993, 188[VP] (Effective publication: Collins and Wallbanks 1992, 239.) (*Streptococcus parvulus ex* Weinberg, Nativelle and Prévot 1937, Cato 1983, 83)

par′vu.lus. L. neut. dim. adj. *parvulus* somewhat small.

Obligately anaerobic, nonmotile, nonspore-forming, Gram-stain-positive cocci (approx. 0.3–0.6 μm in diameter) that occur singly, in pairs, in clumps, and in short chains. Occasional elongate cells, some with a central swelling, may occur in stained preparations prepared from growth in media without Tween 80. Colonies on brain heart blood agar are pinpoint to 1 mm in diameter, raised or low convex,

circular, entire, translucent to transparent, and colorless to gray after 2–5 d of anaerobic incubation at 37°C. Growth is stimulated (30 out of 30 tested strains) in culture media supplemented with 0.02% (v/v) Tween 80 and with 10% (v/v) rabbit serum. Of 72 strains tested, 58 grew at 45°C, and 6 out of 67 strains grew in the presence of 6.5% (w/v) NaCl.

The fermentation products from glucose are lactic acid (0.7–6.3 meq/100 ml of culture; mean for 40 strains, 4.2 meq/100 ml), acetic acid (0.1–0.6 meq/100 ml; mean for 40 strains, 0.3 meq/100 ml), formic acid (0–0.3 meq/100 ml) and occasionally trace amounts of succinic acid. Little, if any, gas is detected in deep agar cultures. Hydrogen is not produced. The terminal pH range in PYG-Tween 80 broth cultures is 4.0–5.1; the mean terminal pH for 32 strains was 4.4.

A total of 11 out of 82 tested strains fermented esculin; 1 out of 68, glycerol; 1 out of 82, melibiose; and 16 out of 82, xylose. Amygdalin, erythritol, glycogen, inositol, mannitol, melezitose, raffinose, rhamnose, sorbitol, and starch are not fermented.

Starch is not hydrolyzed in the absence of added serum (which contains amylase). Gelatin is not liquefied, meat is not digested, indole is not produced, and nitrate is not reduced. Reactions are usually negative for bile-esculin (none out of 68 tested strains were positive), DNase (1 out of 68 strains positive), and hippurate hydrolysis (none of 68 strains positive). Catalase activity is not detected.

Susceptibility to antibiotics varies; 1 out of 82 tested strains were resistant (μg per ml) to chloramphenicol (12), 10 out of 82 to clindamycin (1.6), 5 out of 82 to erythromycin (3), 6 out of 82 to penicillin G (2U), and 1 out of 82 to tetracycline (6).

The major cellular fatty acid derivatives are $C_{18:1}$ *cis*9 fatty acid methyl ester and $C_{18:1}$ dimethylacetyl.

Source: human gingival crevices and, according to Prévot et al. (1967), from patients with pulmonary gangrene, tonsillitis, sinusitis, otitis, and dental and thoracic abscesses.

DNA G+C content (mol%): 39 (T_m).

Type strain: ATCC 33793, CCUG 32760, CIP 102970, DSM 20469, IPP 1246, JCM 10300, VPI 0546.

Sequence accession no. (16S rRNA gene): S44206, X67150.

4. **Atopobium rimae** (Olsen, Johnson, Moore and Moore 1991) Collins and Wallbanks 1993, 188[VP] (Effective publication: Wallbanks and Collins 1992, 239; *Lactobacillus rimae* Olsen, Johnson, Moore and Moore 1991, 264.)

ri′mae. L. gen. n. *rimae* of a fissure, pertaining to the gingival crevice.

Strictly anaerobic, small, elliptical, nonmotile, Gram-stain-positive rods occur singly, in pairs, and in short chains. Central swellings may occur, particularly in cells grown on solid medium. Colonies on brain heart blood agar are 1–2 mm in diameter, raised or low convex, entire, and translucent to transparent after 5 d of anaerobic incubation at 37°C. Growth is stimulated by 0.02% (v/v) Tween 80 and usually when 10% (v/v) rabbit serum (45 out of 53 strains) is added to culture media. Of 33 tested strains, 21 grew at 45°C. There is no growth in the presence of 6.5% (w/v) NaCl.

The fermentation products from glucose are lactic acid (1–10 meq/100 ml of culture; mean for 33 strains, 4.7 meq/100 ml), acetic acid (0.2–0.6 meq/100 ml; mean for 33 strains, 0.3 meq/100 ml), formic acid (0–0.4 meq/100 ml; mean, 0.05 meq/100 ml), and occasionally trace amounts of succinic acid. Little, if any, gas is detected in deep agar cultures. Hydrogen is not produced. The range of terminal pH of PYG-Tween 80 broth cultures is 3.8–4.9; the mean terminal pH for 30 strains was 4.3.

Glycogen is fermented only when serum (which contains amylase) is added to the medium. In the absence of serum, starch is seldom fermented (1 out of 66 strains positive) or hydrolyzed (11 out of 66 strains positive). Amygdalin, erythritol, and esculin are rarely fermented (1 out of 76 strains positive), glycerol, inositol, mannitol, melezitose, melibiose, raffinose, rhamnose, sorbitol, and xylose are not fermented.

Gelatin is not liquefied, meat is not digested, indole is not produced, and nitrate is not reduced. Reactions are negative for bile-esculin, DNase, and hippurate hydrolysis. Catalase activity is not detected.

Susceptibility to antibiotics: none of the 70 tested strains were resistant (μg per ml) to chloramphenicol (12), clindamycin (1.6), erythromycin (3), or tetracycline (6); 5 out of 70 strains were resistant to penicillin G (2U).

The major cellular fatty acid derivatives are $C_{18:1}$ *cis*9 fatty acid methyl ester and $C_{18:1}$ dimethylacetyl.

Source: human gingival crevices, especially in patients with periodontitis.

DNA G+C content (mol%): 45 (T_m).

Type strain: ATCC 49626, CCUG 31168, DSM 7090, NBRC 15546, NCFB 2896, JCM 10299, LMG 11476, VPI D140H-11A.

Sequence accession no. (16S rRNA gene): S44205, AF292371.

Additional comments: formerly known as *Lactobacillus* DO2.

5. **Atopobium vaginae** Rodriguez-Jovita, Collins, Sjödén and Falsen 1999, 1575[VP]

va.gi′nae. L. n. *vagina* vagina; L. gen. n. *vaginae* of the vagina.

Facultatively anaerobic, small-elongated Gram-stain-positive cocci occur singly, in pairs, or short chains. Tiny pin-head colonies are formed on blood agar at 37°C.

Acid is not produced from mannose or raffinose.

Positive for arginine dihydrolase, arginine arylamidase, acid phosphatase, glycine arylamidase, histidine, arylamidase, leucine arylamidase, proline arylamidase and serine arylamidase, but negative for alanine arylamidase, α-arabinosidase, cystine arylamidase, chymotrypsin, ester lipase C8, esterase C4, α-fucosidase, α- and β-galactosidase, β-galactosidase 6-phosphate, α- and β-glucosidase, glutamic acid decarboxylase, glutamylglutamic acid arylamidase, β-glucuronidase, α-mannosidase, β-*N*-acetylglucosaminidase, lipase C14, pyroglutamic acid arylamidase, tyrosine arylamidase, trypsin, and urease. Weak activity for phenylalanine arylamidase may be detected. Indole-negative. Nitrate is not reduced. Gelatin and esculin are not hydrolyzed.

Source: vaginal flora of a healthy person. Habitat is unknown.

DNA G+C content (mol%): 44 (T_m).

Type strain: ATCC BAA-55, CCUG 38953, CIP 106431, DSM 15829.

Sequence accession no. (16S rRNA gene): Y17195.

Genus III. **Collinsella** Kageyama, Benno and Nakase 1999c, 564$^{\mathrm{VP}}$

Akiko Kageyama and Yoshimi Benno

Col.lin.sel′la. N.L. fem. dim. ending *-ella*; N.L. fem. n. *Collinsella* named to honor Matthew D. Collins, a contemporary English microbiologist, for his outstanding contributions to microbial systematics.

Gram-stain-positive, obligatory anaerobic organism which forms chains of rods (0.3–0.7 × 1.2–4.3 μm). **Does not form spores or flagella**. Colonies are produced in 2 d at 37°C on EG agar in an anaerobic jar containing 100% CO_2. **Fermentation products of glucose are ethanol, formate, hydrogen, and lactate**. Cell wall contains an A4 type peptidoglycan. The 16S rDNA sequence analysis shows that the organism is a member of the family *Coriobacteriaceae*, which also includes the genera *Atopobium*, *Coriobacterium*, *Cryptobacterium*, *Denitrobacterium*, *Eggerthella*, *Olsenella*, and *Slackia*.

DNA G+C content (mol%): 60–65 (HPLC).

Type species: **Collinsella aerofaciens** (Eggerth 1935) Kageyama, Benno and Nakase 1999c, 564$^{\mathrm{VP}}$.

Further descriptive information

16S rRNA gene sequence data show that the genus *Collinsella* is closely related to the genus *Coriobacterium* of the family *Coriobacteriaceae*, class *Coriobacteriales* Stackebrandt et al. 1997 (Figure 417). Almost complete 16S rRNA gene sequences (positions 28–1491; *Escherichia coli* numbering system) have been determined for *Collinsella* strains. The range of sequence similarity values is 96.6–97.8% for *Collinsella aerofaciens* strains, and 98.2–99.5% for *Collinsella stercoris* strains; *Collinsella intestinalis* strains share a 99.6% sequence similarity.

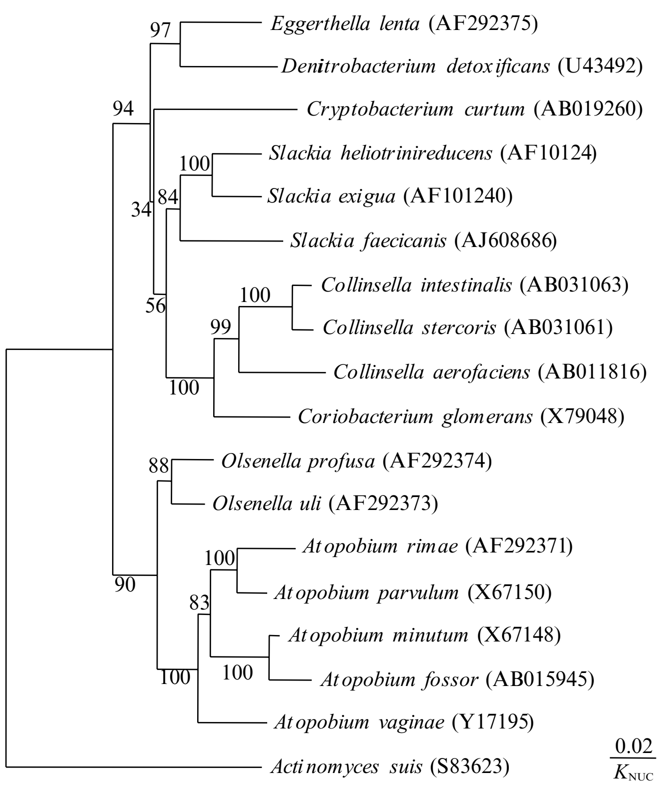

FIGURE 417. Phylogenetic tree derived from 16S rRNA gene sequences of the members of the family *Coriobacteriaceae* and constructed using the neighbor-joining method and K_{nuc} values. Numbers at branching points are bootstrap values (1000 resamplings). The tree was unrooted and *Actinomyces suis* was used as an outgroup.

Species-specific primers have been designed for the three *Collinsella* species. *Collinsella aerofaciens*-specific primers AERO-F (5′-CTTTCAGCAGGGAAGAGTCAA-3′; positions 436–466; *Escherichia coli* numbering system) and AERO-R (5′-AGCCATGCACCACCTGTATGG-3′; positions 1060–1039; *Escherichia coli* numbering system) generate an amplicon of about 590 bp; optimum PCR results are obtained at 63°C after 25 cycles. Similarly, *Collinsella intestinalis*-specific primers INTE-F (5′-CTTACCAGGGCTTGACATGA-3′; positions 980–999; *Escherichia coli* numbering system) and INRE-R (5′-TTAGGCGCCTCCCCCCAGAT-3′; positions 1469–1450; *Escherichia coli* numbering system) yield an amplicon of about 486 bp; optimum PCR results are obtained at 58°C after 25 cycles. Finally, *Collinsella stercoris*-specific primers STER-F (5′-TGCAAGTCGAACGGCACCCG-3′; positions 56–75; *Escherichia coli* numbering system) and STER-R (5′-CCGTCTGGGCTTTGCCGGCC-3′; positions 223–204; *Escherichia coli* numbering system) produce an amplicon of about 158 bp; optimum PCR results are obtained at 58°C and after 25 cycles.

Collinsella strains have an A4-type peptidoglycan (Schleifer and Kandler, 1972). *Collinsella aerofaciens* has an A4β-type peptidoglycan with a (L-Ala)–D-Glu–L-Orn–L-Asp peptide subunit and an interpeptide bridge which only contains L-asparagine moieties; *Collinsella intestinalis* an A4α-type peptidoglycan with a (L-Ala)–D-Glu–L-Lys–D-Glu peptide subunit and interpeptide bridge consisting of D-glutamic acid moieties, and *Collinsella stercoris* an A4β-type peptidoglycan with a (L-Ala)–D-Glu–L-Orn–D-Asp peptide subunit and an interpeptide bridge containing D-asparagine moieties.

The antibiotic sensitivity pattern of *Collinsella* strains, including 32 strains of *Collinsella aerofaciens*, eight strains of *Collinsella stercoris*, and two strains of *Collinsella intestinalis*, has been determined (Table 308). *Collinsella* strains are sensitive to various antibiotics, but not to ceftazidime or cefotetan (MIC: 12.5–25 μg/ml), or to aztreonam or carumonam (MIC: <100 μg/ml).

Collinsella aerofaciens is the most abundant bacterium in the human intestine [about 10^{10} cells (g feces)/min], and is found in more than 90% of human intestines (Benno et al., 1986; Finegold and Sutter, 1978; Moore and Holdeman, 1974). *Collinsella intestinalis* and *Collinsella stercoris* are also present in the human intestine. None of these three species exhibit pathogenicity.

Enrichment and isolation procedures

Strains of *Collinsella* species can be isolated from human feces of patients with colon cancer, Crohn's disease, and ulcerative colitis, and from healthy individuals on EG agar medium* and

*Premixed EG agar (Eiken Chemical Co., Ltd.) supplemented with 5% horse blood contains 3 g of beef extract, 5 g of yeast extract, 10 g of peptone, 1.5 g of glucose, 0.5 g of L-cysteine HCl, 0.2 g of L-cystine, 4 g of Na_2HPO_4, 0.5 g of soluble starch,, 0.5 g of polysorbate 80, 0.5 g of silicone, and 15 g of agar in 1000 ml of distilled water, pH 7.7.

TABLE 308. Susceptibilities of *Collinsella aerofaciens*, *Collinsella intestinalis*, and *Collinsella stercoris* to antimicrobial agents

Organism and antimicrobial agent	MIC (mg/ml) Range	50%	90%	MIC (mg/ml) for type strain

in EGF broth.* Organisms are cultivated for 2 d at 37°C in an anaerobic chamber using these media.

Maintenance procedures

Collinsella strains can be maintained for several weeks on EG agar plates in an anaerobic jar containing 100% CO_2. Long-term storage can be achieved at −80°C in 10% glycerol or by lyophilization in the presence of stabilizers such as 10% skim milk.

Differentiation of the genus *Collinsella* from other genera

A number of characteristics that can be used to distinguish the genus *Collinsella* from other genera classified in family *Coriobacteriaceae* are shown in Table 307. These properties include fermentation end products. Specific primers can also be used to distinguish *Collinsella* strains from the other genera.

*Contains 2.4 g of Lab-Lemco powder (Oxoid), 10 g of proteose peptone No.3 (Difco), 5 g of yeast extract (Difco), 4 g of Na_2HPO_4, 40 ml of sterilized horse blood, 5 g of glucose, 0.5 g of soluble starch (Sigma) and 0.5 g of L-cysteine HCl in 960 ml of distilled water, pH 7.6.

Taxonomic comments

Eubacterium aerofaciens was reclassified as *Collinsella aerofaciens* by Kageyama et al. (1999c). Moore et al. (1971) had reported that these organisms belonged to the genus *Eubacterium* because they were Gram-stain-positive, obligatorily anaerobic, non-spore-forming rods that did not produce propionic acid as a major product (*Propionibacterium*); lactic acid as a sole major acid (*Lactobacillus*); large amounts of succinic (in the presence of CO_2) and lactic acids, sometimes with acetic and formic acids (*Actinomyces*); or acetic and lactic acids (acetic > lactic), with or without formic acid, as sole major acid products (*Bifidobacterium*). The genus *Eubacterium* had a broad definition and acted as a repository for large numbers of phenotypically diverse species (Andreesen, 1992).

The type species of the genus *Eubacterium* is *Eubacterium limosum*. It was evident from several studies that *Eubacterium barkeri*, *Eubacterium callanderi*, and *Eubacterium limosum* (Mountfort et al., 1988) formed the nucleus of the redefined genus *Eubacterium*. Based on the characteristics of this group, a preliminary working definition of *Eubacterium sensu stricto* was proposed: Gram-stain-positive, rod-shaped nonmotile obligatory anaerobic organisms which may form endospores, are saccharoclastic, produce acetate, butyrate, lactate, and H_2, and formate or CO_2 as products of glucose fermentation. The cell wall has a type B peptidoglycan and the G+C content of the DNA is within the range 45–47 mol% (Willems and Collins, 1996).

Some species classified in the genus *Eubacterium*, but not assigned to *Eubacterium sensu stricto*, have been transferred to established or new genera (Kageyama et al., 1999b, 1999c; Ludwig et al., 1992; Wade et al., 1999; Willems et al., 1997). *Eubacterium aerofaciens* was reclassified to the novel genus *Collinsella* based on phylogenetic characteristics and cell-wall peptidoglycan type (Kageyama et al., 1999c). Subsequently, two new *Collinsella* species were proposed, *Collinsella intestinalis* and *Collinsella stercoris*, and the description of genus *Collinsella* was emended (Kageyama and Benno, 2000).

Differentiation of species of the genus *Collinsella*

Properties which can be used to distinguish between *Collinsella* species are shown in Table 309 and Table 310. Species specific primers also can be used for species differentiation.

TABLE 309. Differences in antibiotic susceptibilities between *Collinsella* species

	MIC_{90} (mg/ml)[a]

List of species of the genus *Collinsella*

1. **Collinsella aerofaciens** (Eggerth 1935) Kageyama, Benno and Nakase 1999c, 564[VP] [*Eubacterium aerofaciens* (Eggerth 1935) Prévot 1938, 295[AL]]

ae.ro.fa′ci.ens. Gr. n. *aer*, *aeros* air, gas; L. v. *facere* to make, to produce; N.L. part. adj. *aerofaciens* gas-producing.

Gram-stain-positive, obligatory anaerobic organism which occur in chains of 6–120 cells (0.3–0.7×1.2–4.3 µm). Spores and flagella are absent. Colonies are white in the center with clear surroundings and exhibit protuberances on EG agar. Can be cultivated in 2 d at 37°C on EG agar in an anaerobic jar containing 100% CO_2. Acid is produced from fructose, galactose, glucose, lactose, maltose, and mannose, but not from arabinose, erythritol, glycogen, inositol, mannitol, melezitose, soluble starch, sorbitol, or xylose. Has an A4β-type peptidoglycan with a (l-Ala)–d-Glu–l-Orn–l-Asp peptide subunit and interpeptide bridge composed of l-asparagine moieties.

Source: human feces.

DNA G+C content (mol%): 61 (HPLC).

Type strain: JCM 10188, ATCC 25986, CCUG 28087, DSM 3979, NCTC 11838, VPI 1003.

Sequence accession no. (16S rRNA gene): AB011816.

2. **Collinsella intestinalis** Kageyama and Benno 2000, 1773[VP]

in′test.in.alis. n. *intestinum* gut, intestine; L. suff. *-alis* suffix denoting pertaining to; N.L. masc. adj. *intestinalis* pertaining to the intestine.

Gram-stain-positive, obligate anaerobic organism that occur in chains of 2–20 cells (0.3–0.5 × 1.2–2.2 µm). Colonies are white or gray in the center with clear margins on EG agar. Spores and flagella are absent. Grows on EG agar after 2 d at 37°C in an anaerobic jar containing 100% CO_2. Acid is produced from cellobiose, fructose, galactose, glucose, mannose, ribose, and salicin, but not from amygdalin, l-arabinose, erythritol, esculin, glycogen, inositol, lactose, maltose, mannitol, melezitose, raffinose, rhamnose, sorbitol, starch, sucrose, trehalose, or d-xylose. Positive for leucine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, and *N*-acetyl-β-glucosaminidase, but negative for chymotrypsin, cystine arylamidase, α-fucosidase, α-galactosidase, β-glucuronidase, lipase (C4), α-mannosidase, trypsin, and valine arylamidase. Has an A4α type peptidoglycan with a (l-Ala)–d-Glu–l-Lys–d-Glu peptide subunit, and interpeptide bridge composed of d-glucose moieties.

Source: human feces.

DNA G+C content (mol%): 64.4 (HPLC).

Type strain: JCM 10643, DSM 13280, RCA56-68, CCUG 45296, CIP 106914.

Sequence accession no. (16S rRNA gene): AB031063.

3. **Collinsella stercoris** Kageyama and Benno 2000, 1773[VP]

ster′co.ris. L. n. *stercus -oris* dung, excrement, feces; L. gen. n. *stercoris* of feces, referring to source of the isolate.

Gram-stain-positive, obligate anaerobic organism which occurs in chains of 2–20 cells (0.3–0.4 × 1.3–2.4 µm). Colonies are white or gray in the center with clear margins on EG agar. Spores and flagella are absent. Grows on EG agar in 2 d at 37°C in an anaerobic jar containing 100% CO_2.

Acid is produced from cellobiose, fructose, galactose, glucose, lactose, maltose, mannose and salicin, but not from amygdalin, L-arabinose, erythritol, esculin, glycogen, inositol, mannitol, melezitose, raffinose, rhamnose, ribose, sorbitol, starch, sucrose, trehalose or D-xylose. Positive for acid phosphatase, β-galactosidase, leucine arylamidase, naphthol-AS-BI-phosphohydrolase, and *N*-acetyl-β-glucosaminidase-positive, but negative for chymotrypsin, cystine arylamidase, α-fucosidase, α-galactosidase, β-glucuronidase, lipase (C4), α-mannosidase, trypsin, or valine arylamidase. Has an A4β type peptidoglycan with a (L-Ala)–D-Glu–L-Orn–D-Asp peptide subunit, and interpeptide bridge consisting only of D-asparagine moieties.

Source: human feces.

DNA G+C content (mol%): 61.2 (HPLC).

Type strain: JCM 10641, DSM 13279, RCA55-54, CCUG 45295, CIP 106913.

Sequence accession no. (16S rRNA gene): AB031061.

Genus IV. **Cryptobacterium** Nakazawa, Poco, Ikeda, Sato, Kalfas, Sundqvist and Hoshino 1999, 1199VP

Futoshi Nakazawa

Crypt.o.bac.te′ri.um. Gr. n. *kruptos* hidden; Gr. n. *bakterion* a small rod; N.L. neut. n. *Cryptobacterium* a hidden rod-shaped bacterium.

Cells are very short rods, 0.4 × 0.8–1.0 µm. Gram-stain-positive, occasionally Gram-stain-negative in stationary phase, having a cell wall typical of Gram-stain-positive bacteria (Figure 418). **Nonmotile, non-sporing, and obligately anaerobic. Catalase-negative. Asaccharolytic and no volatile end product in peptone-yeast extract-glucose broth**. Positive for arginine hydrolysis, negative for nitrate reduction and inert in most conventional biochemical tests. Isolated from the periodontal pocket of an adult human with periodontal disease, and from necrotic dental pulp.

DNA G+C content (mol%): 50–51 (T_m).

Type species: **Cryptobacterium curtum** Nakazawa, Poco, Ikeda, Sato, Kalfas, Sundqvist and Hoshino 1999, 1199VP.

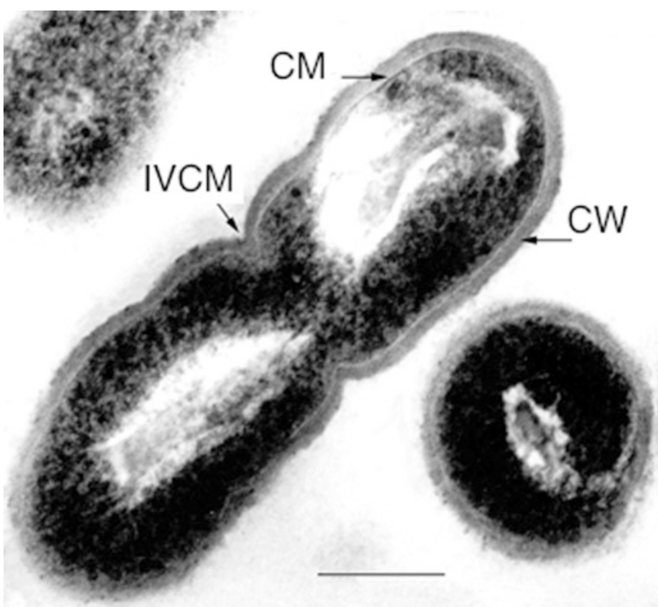

FIGURE 418. Transmission electron microphotograph of *Cryptobacterium curtum*. CM, cytoplasmic membrane; CW, cell wall, IVCM, invagination of cytoplasmic membrane.

Enrichment and isolation procedures

Growth in broth media is very poor with or without carbohydrates. *Cryptobacterium* forms circular, convex, and translucent colonies on BHI-blood agar plates, which are about 0.3–0.5 mm in diameter. Colonies are less than 1 mm in diameter even after prolonged incubation. Hemolysis does not occur around colonies on BHI-blood agar plates.

Differentiation of the genus *Cryptobacterium* from other genera

According to the results of 16S rRNA gene sequence analyses, the genus *Cryptobacterium* belongs to the family *Coriobacteriaceae* which contains anaerobic, asaccharolytic, Gram-stain-positive rods. DNA–DNA hybridization studies indicate that the genus *Cryptobacterium* shows low levels (1–2%) of DNA relatedness against closely related taxa such as the genera *Collinsella*, *Eggerthella* (Nakazawa and Hoshino, 2004), *Mogibacterium* (Nakazawa et al., 2000, 2002), and *Slackia*. The genus *Cryptobacterium* can also be distinguished by restriction fragment length polymorphism (RFLP) analysis of 16S rDNA using the endonucleases *Alu*I and *Smf*. SDS-PAGE analysis of whole-cell proteins and Western blotting reactions with rabbit antisera also allow the genus *Cryptobacterium* to be distinguished from related genera. In addition, the genus can be differentiated from the genera *Collinsella*, *Eggerthella*, and *Slackia* by metabolic end products, arginine hydrolysis, and nitrate reduction.

Taxonomic comments

Initially organisms now classified as *Cryptobacterium* species were isolated from the human oral cavity as anaerobic, asaccharolytic, *Eubacterium*-like isolates. However, these isolates were inert in most conventional biochemical tests and could not be assigned to previously established bacterial species. The genus *Cryptobacterium*, with *Cryptobacterium curtum* as the type strain, was described on the basis of a polyphasic taxonomic study, notably by using 16S rRNA gene sequence and DNA–DNA hybridization data.

List of species of the genus *Cryptobacterium*

1. **Cryptobacterium curtum** Nakazawa, Poco, Ikeda, Sato, Kalfas, Sundqvist and Hoshino 1999, 1199[VP]

cur′tum. L. neut. adj. *curtum* shortened (a shortened cell of this organism).

Cells are very short, Gram-stain-positive, obligately anaerobic, nonmotile, non-sporing rods which occur singly or in masses, and which sometimes stain Gram-negative in older cultures. On BHI-blood agar plates they form minute circular, convex, translucent colonies less than 1 mm in diameter, even after prolonged incubation in an anaerobic glove box. Growth in broth media is poor with or without carbohydrates. Hemolysis does not occur on BHI-blood agar plates. They are inert in most biochemical tests. Neither esculin nor starch are hydrolyzed. Does not reduce nitrate or liquefy gelatin. Negative for catalase, indole, and urease. Ammonia is produced from arginine. Nonfermentative and do not utilize adonitol, amygdalin, arabinose, cellobiose, erythritol, esculin, fructose, galactose, glucose, glycogen, inositol, lactose, maltose, mannitol, mannose, melezitose, melibiose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose, or xylose. No metabolic end product is detected in peptone-yeast extract medium supplemented with glucose or peptone-yeast extract-glucose broth.

Source: the periodontal pocket of an adult human with periodontal disease, and from necrotic dental pulp.

DNA G+C content (mol%): 50–51 (HPLC).

Type strain: 12-3, ATCC 700863.

Sequence accession no. (16S rRNA gene): AB019260.

Genus V. **Denitrobacterium** Anderson, Rasmussen, Jensen and Allison 2000, 633[VP]

Robin C. Anderson and Thaddeus B. Stanton

De.nit.ro.bac.te′ri.um. L. pref. *de* from; L. n. *nitro* nitrocompound; Gr. neut. dim. n. *bakterion* a small rod; N.L. neut. n. *Denitrobacterium* named for a nitrocompound-reducing rod-shaped bacterium.

Rod-shaped cells (0.5–1.0 × 1.0–1.5 µm). Cells may possess irregular, bulbous ends. **Gram-stain-positive, non-sporulating**, and **nonmotile**. Strictly **anaerobic** chemo-organotroph; growth is supported by suitable electron acceptors and is proportional to amount of acceptor reduced. **Nonfermentative.** Growth occurs in anaerobic media containing clarified ruminal fluid, peptone, and a suitable electron acceptor. **Dimethyl sulfoxide, nitroethane, 3-nitropropan-1-ol, 2-nitropropan-1-ol, 3-nitropropionate, trimethyl amine-oxide and, by some strains, nitrate, may be used as electron acceptors and support good growth**. **Nitroethanol, 2-nitrobutane, and 1-nitropropane also may be used as electron acceptors, but growth with these compounds is marginal, presumably due to the accumulation of toxic end products. Azide, chlorate, fumarate, nitrite, 2-nitrobenzene, perchlorate, sulfate, and sulfite do not support growth.** Little if any acid is produced during growth in medium with hydrogen or formate as electron donor. **Hydrogen, formate, and (DL)-lactate can be used as electron donors**; acetate is produced when grown with lactate. **Gelatin is not hydrolyzed, indole and H_2S are not produced**. Palmitic acid ($C_{14:0}$) is the predominant cellular fatty acid of cells grown in modified brain heart infusion medium, although an abundance of other straight and branched chain fatty acids, aldehydes, and dimethyl acetals are present. Cells contain a *c*-type cytochrome. Isolated from bovine ruminal contents. A single species of *Denitrobacterium*, *Denitrobacterium detoxificans*, has been characterized. The results of 16S rRNA gene sequence analysis indicate *Denitrobacterium* belongs to the *Actinobacteria* (Figure 419).

DNA G+C content (mol%): 56–61 (T_m).

Type species: **Denitrobacterium detoxificans** Anderson, Rasmussen, Jensen and Allison 2000, 633[VP].

Further descriptive information

Based on 16S rRNA gene sequence analysis, the genus *Denitrobacterium* falls within class *Actinobacteria*, subclass *Coriobacteridae*, order *Coriobacteriales*, suborder *Coriobacterineae*, family *Coriobacteriaceae*. A single species, *Denitrobacterium detoxificans*, has been named. *Denitrobacterium* is most closely related to the genus *Eggerthella* (Figure 419).

Cells of *Denitrobacterium detoxificans* are rod-shaped (0.5–1.0 × 1.0–1.5 µm), stain Gram-positive, and do not react with 3% KOH to yield a slimy interface typical of Gram-stain-negative cell types (Gregersen, 1978). Electron micrographs of thin sections reveal Gram-stain-positive cell-wall structures and the presence of unidentified inclusion bodies (Anderson et al., 1997). Stains for spores or known types of inclusion bodies such as polyphosphate granules, glycogen, starch, or poly β-hydroxybutyrate are all negative. Cells do not survive treatment for 10 min at 80°C (Anderson et al., 1997). Flagella are not observed (Anderson et al., 1997).

Palmitic acid ($C_{14:0}$) is the predominant fatty acid present in cells grown in modified brain heart infusion medium; however, considerable amounts of other straight and branched chain fatty acids (C_{12} to C_{18}), as well as aldehydes and dimethyl acetals, are also present (Anderson et al., 1997, 2000). Cells contain a *c*-type cytochrome (Anderson et al., 1997).

Denitrobacterium detoxificans obtains energy for growth exclusively via anaerobic respiration, coupling the oxidation of hydrogen, formate, or lactate to the reduction of suitable anaerobic electron acceptors such as dimethyl sulfoxide, nitroethane, 3-nitropropan-1-ol, 2-nitropropan-1-ol, 3-nitropropionate, nitroethanol, 1-nitropropane, 2-nitrobutane, and trimethyl amine-oxide. Nitrate is also used as an electron acceptor and is reduced to ammonia by the type strain *Denitrobacterium*

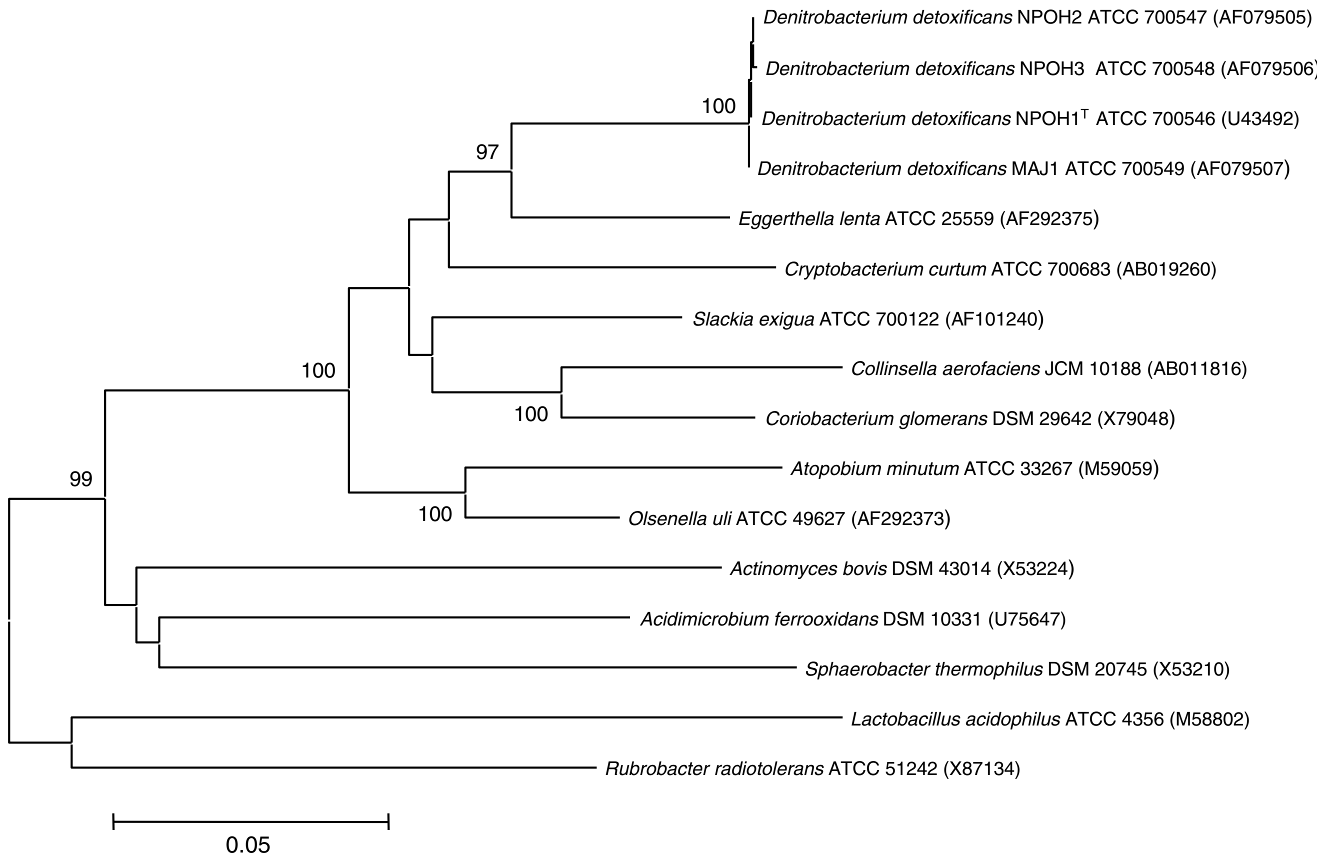

FIGURE 419. Phylogenetic tree based on 16S rRNA gene sequences of *Denitrobacterium detoxificans* strains and type strains of their closest relatives. Phylogenetic and molecular evolutionary analyses were conducted using MEGA version 2.1 (Kumar et al., 2001). Sequence alignments were based on 1592 nucleotide positions and compared by Jukes–Cantor analysis. The tree was constructed using the neighbor-joining method. Scale bar represents a 5% difference in nucleotide sequence. Bootstrap values greater than 95 and based on 1000 replicates are indicated near branch points.

detoxificans NPOH1^T, but not by any of the other three strains tested, NPOH2, NPOH3, and MAJ1 (Anderson et al., 2000).

Denitrobacterium strains are routinely cultured in anaerobic medium B* (Anderson et al., 1996) supplemented with an appropriate source of reductant and electron acceptor. Reductant (provided as 16 mM sodium formate) and acceptor (provided as 3-nitropropionate; generally 5–10 mM) support good growth and are convenient to prepare, filter-sterilize, and to add to previously prepared medium. Dimethyl sulfoxide, nitroethane, 3-nitropropan-1-ol, trimethyl amine-oxide, and, in the case of strain NPOH1^T, nitrate also support good growth, whereas nitroethanol, 2-nitrobutane, and 1-nitropropane do not. Reductant can also be provided as H_2 in the gas phase or as lactate (Anderson et al., 1997). Undefined nutritional factors in phytone are important for maximum growth of all four strains tested.

Cells of *Denitrobacterium detoxificans* NPOH1^T exhibit a positive reaction for arginine aminopeptidase and a weakly positive alkaline phosphatase reaction in the AN-IDENT test system; they exhibit positive reactions for phosphatase acid and naphthol-AS-BI-phosphorohydrolase and a weak positive reaction for lipase-C14 in the API ZYM test system (Anderson et al., 1997). Reactions to all other AN-IDENT and API ZYM tests are negative.

Of the four strains of *Denitrobacterium detoxificans* analyzed, all share >99% 16S rRNA gene sequence similarity.

Denitrobacterium detoxificans strain NPOH1^T exhibits sensitivity to 6 μg/ml cephalothin, 12 μg/ml, chloramphenicol, 1.6 μg/ml clindamycin, and 3 μg/ml erythromycin, and is resistant to 4 μg/ml ampicillin, 100 μg/ml carbenicillin, 2 U/ml penicillin, and 6 μg/ml tetracycline (Anderson et al., 1997).

Denitrobacterium detoxificans strains were isolated from bovine ruminal contents enriched for enhanced rates of 3-nitropropionic acid or 3-nitropropan-1-ol metabolism (Anderson et al.,

*Medium B contains clarified ruminal fluid at 8% (v/v) and (mg/liter): K_2HPO_4, 225.0; KH_2PO_4, 225.0; $(NH_4)_2SO_4$, 450.0; NaCl, 450.0; $MgSO_4 \cdot 7H_2O$, 45.0; $CaCl_2$, 22.5; thiamine, 2.0, pantothenate, 2.0; nicotinamide, 2.0; pyridoxine-HCl, 2.0; riboflavin, 2.0; *p*-aminobenzoic acid, 1.0; biotin, 0.05; folic acid, 0.05; lipoic acid, 0.05; vitamin B-12, 0.02; resazurin, 1.0; cysteine-HCl, 500.0; Na_2CO_3, 4000.0; phytone peptone, 8000.0. Clarified ruminal fluid is prepared by autoclaving freshly collected ruminal fluid that had been strained through cheese cloth or nylon paint strainers and then centrifuging at least twice at 10,000 *g* to remove particulate matter. Cysteine-HCl and Na_2CO_3 are added after the medium containing the other ingredients is adjusted to pH 6.8. The complete medium is boiled and then cooled on ice while being flushed with oxygen-free CO_2 or H_2CO_2 (50:50). When cooled, the medium is anaerobically distributed to culture tubes (Bryant, 1972) which are immediately closed with stoppers and autoclaved.

1996, 1997). 3-Nitropropionic acid or 3-nitropropan-1-ol are toxic constituents of some forages, notably many *Astragalus* species (milkvetches), known to cause poisoning of grazing ruminants (Anderson et al., 2005). Strain NPOH1^{T} was isolated from ruminal contents from a cow reared at the National Animal Disease Center (NADC) in Ames, Iowa; strains NPOH2 and NPOH3 were isolated likewise from ruminal contents from a different cow reared at the same facility and strain MAJ1 was isolated from ruminal contents from a cow reared in British Columbia. Rates of ruminal nitrotoxin metabolism are markedly increased when cattle are fed sublethal amounts of nitro-containing forage or nitroethane, a nontoxic analog, thus implicating a selection mechanism to enrich for bacteria like *Denitrobacterium detoxificans*, which can confer protection to the host (Anderson, 1998; Majak, 1992b, 1992a; Majak et al., 1986). *Denitrobacterium detoxificans*-like 16S rDNA has been detected in a carious dental sample (Chhour et al., 2005).

Enrichment and isolation procedures

Denitrobacterium can be isolated by enriching anaerobic nitro-respiring bacteria. *Denitrobacterium detoxificans* was isolated from ruminal contents enriched from 3×10^4 cells/ml ruminal fluid to $>10^7$ cells/ml during consecutive (24 h intervals at 39°C) batch culture in a minimal ruminal fluid medium supplemented with gradually increasing concentrations (5–10 mM) of 3-nitropropionic acid or 3-nitropropan-1-ol (Anderson et al., 1996). Concentrations of other bacteria decreased concurrently during the enrichment to approximately 10^7 cells/ml. Anaerobic techniques for both broth and agar (2%) medium (Bryant, 1972) were used during enrichment and colony isolation. Hydrogen (50% in CO_2) in the gas phase served as reductant during the isolations although 16 mM formate, which supports nearly equal amounts of growth (Anderson et al., 1997), may work equally well. Isolates picked at random from roll tubes containing solidified medium B were cultured in nitro-supplemented medium B broth. The isolates that grew and reduced nearly all of the added 3-nitropropionic acid or 3-nitropropan-1-ol, as determined via colorimetric analysis of spent culture fluid (Anderson et al., 1993), were indicative of *Denitrobacterium detoxificans*.

Maintenance procedures

All strains of *Denitrobacterium detoxificans* can be maintained by serial transfer, at 3–4 d intervals, in anaerobically prepared medium B (Anderson et al., 1996) supplemented with 16 mM formate and 9 mM 3-nitropropionic acid. Anaerobic *Denitrobacterium detoxificans* cultures preserved as slants or broths in 20% glycerol can be stored at −80°C for at least 10 years.

Differentiation of the genus *Denitrobacterium* from other genera

Denitrobacterium species can be differentiated from other anaerobic respiring organisms by their obligate respiratory metabolism and their ability to respire on nitroalkane compounds such as 3-nitropropan-1-ol, 2-nitropropan-1-ol, 3-nitropropionic acid, nitroethanol, nitroethane, 1-nitropropane, and 2-nitrobutane but not on other acceptors such as O_2, chlorate, fumarate, perchlorate, sulfate, or sulfite. *Denitrobacterium* species can also be differentiated from other genera by 16S rRNA gene sequence analysis.

Differentiation of species of the genus *Denitrobacterium*

The genus contains a single species, *Denitrobacterium detoxificans*.

List of species of the genus *Denitrobacterium*

1. **Denitrobacterium detoxificans** Anderson, Rasmussen, Jensen and Allison 2000, 633[VP]

   de.tox.if'i.cans. L. pref. *de* from; L. n. *toxicum* poison; L. neut. n. *detoxificans* poison reducer.

   The species description is as stated above for the genus. Isolated from ruminal contents enriched for enhanced rates of 3-nitropropan-1-ol metabolism, the toxic aglycone of miserotoxin (3-nitro-1-propyl-β-D-glucopyranoside). All four strains examined share close (>99%) 16S rRNA gene sequence similarity, and have been deposited in the American Type Culture Collection. The type strain differs from the others (strain NPOH2, ATCC 700547; strain NPOH3, ATCC 700548 and MAJ1, and ATCC 700549) in that it has the ability to reduce nitrate.

   DNA G+C content (mol%): 56–61 (T_m).

   Type strain: NPOH1, ATCC 700546, CCUG 5674.

   Sequence accession no. (16S rRNA gene): U43492.

Genus VI. **Eggerthella** Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 599[VP]

William G. Wade and Floyd E. Dewhirst

Egg.er.thel'la. N.L. fem. n. named to honor Arnold H. Eggerth (1889–1962), who first described the organism later named *Eubacterium lentum*.

Gram-stain-positive obligately **anaerobic bacilli**, **which** are **nonmotile** and do not produce endospores. **Growth** is **stimulated by arginine**. **Acid is not formed** from sugars. The cell wall contains an A4γ-type peptidoglycan with an (L-Ala)–D-Glu–*m*-Dpm–D-Glu peptide subunit with an interpeptide bridge that consists only of D-Glu.

DNA G+C content (mol%): 61–65 (HPLC).

Type species: **Eggerthella lenta** Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 599[VP].

Further descriptive information

Members of this genus and related genera tend to be unreactive in the biochemical tests commonly used for identification and therefore have historically been a difficult group to characterize. The phenotypic description of *Eggerthella lenta*, in particular, has long been known to define a heterogeneous group of organisms isolated from the large intestine of humans and animals. In one study investigating this heterogeneity, 32 strains were divided into 4 groups on the basis of growth stimulation by arginine, production of H_2S, catalase, and bile acid-degrading enzymes (MacDonald et al., 1979). Groups A–C degraded steroids and related molecules, while members of Group D did not display this activity and had a cellular fatty acid composition distinct from the other groups (Verhulst et al., 1987). The type strain was subsequently shown to belong to the Group A–C cluster (Mosca et al., 1998), and the colonies of most strains were shown to fluoresce red under UV light (Mosca et al., 1993). Whether the three groups in this cluster correspond to the three currently validly published species remains to be established. Given the marked phenotypic differences between Group D and Groups A–C, it is likely that Group D strains do not belong to this genus. In addition, the use of a commercially available identification kit has frequently resulted in the mis-identification of oral *Slackia exigua* isolates as *Eggerthella lenta* (Wade et al., 1990). A systematic polyphasic study of a large collection of strains identified as *Eggerthella* by a combination of sequence analysis of 16S rRNA genes and the presence of the characteristic peptidoglycan described above is required. Once this has been done, it will be possible to construct more precise descriptions of the three *Eggerthella* species described to date. It is also likely that additional novel species, and perhaps novel genera, would be detected by such an approach.

Eggerthella species are found in the human large intestine and in clinical specimens from a wide variety of infections including those of the blood and postoperative wounds and various kinds of abscesses found in different parts of the body such as the brain and associated with the rectum, scrotum, and pelvis (Chan and Mercer, 2008; Lattuada et al., 2005; Lau et al., 2004c; Moore et al., 1971; Schwiertz et al., 2000). *Eggerthella lenta* is one of a number of Gram-stain-positive anaerobic bacilli, including *Collinsella aerofaciens*, another member of the *Coriobacteriaceae*, capable of inducing arthritis in a rat model (Severijnen et al., 1990).

Enrichment and isolation procedures

Strains of all species grow readily on horse blood agar forming colonies at least 0.5 mm in diameter after a 48-h anaerobic incubation at 37°C. The inclusion of 0.5% arginine in agar and broth media stimulates the growth of all species.

Maintenance procedures

Strains can be maintained on blood agar incubated anaerobically at 37°C and subcultured weekly. Lyophilization of cultures in the early stationary phase of growth is recommended for long-term storage of most strains. Strains can also be stored at −70°C in Brain Heart Infusion broth supplemented with 10% glycerol.

Procedures for testing special characters

The general methods described for the characterization of anaerobes in the VPI *Anaerobe Laboratory Manual* (Holdeman et al., 1977b) and the *Wadsworth-KTL Anaerobic Bacteriology Manual* (Jousimies-Somer et al., 2002a) are suitable for the study of members of this genus. The RapidID 32A anaerobe identification kit (bioMérieux) includes tests useful for the differentiation of the species of this genus. However, as mentioned above, identification by 16S rRNA gene sequencing is the most reliable method for this group and will also detect as yet un-named taxa.

Differentiation of the genus *Eggerthella* from other genera

Key characteristics of *Eggerthella* and related genera are shown in Table 307.

Taxonomic comments

Eggerthella lenta was originally described as a member of the genus *Eubacterium*, but was shown by 16S rRNA gene sequence analysis to belong to the family *Coriobacteriaceae* within the phylum *Actinobacteria*, while *Eubacterium limosum*, the type species of *Eubacterium*, is in the *Firmicutes* (Kageyama et al., 1999a; Wade et al., 1999). A new genus, *Eggerthella*, was proposed to accommodate this species (Wade et al., 1999) and two additional species were subsequently described (Lau et al., 2004b). The phylogenetic relationship between the genus *Eggerthella* and related genera within the family *Coriobacteriaceae* can be seen in the tree constructed from 16S rRNA gene comparisons in Figure 420.

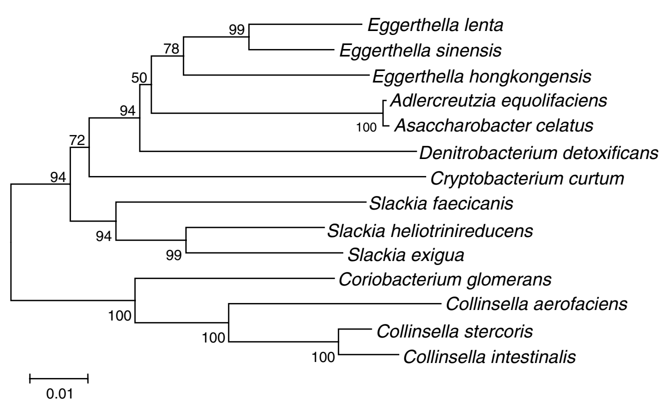

FIGURE 420. Neighbor-joining tree based on 16S rRNA gene sequence comparisons over 1367 aligned bases showing relationships between *Eggerthella* species and between them and related genera. Numbers at the nodes represent bootstrap values for each branch based on data for 100 trees; only values greater than 50% are shown. Bar = 0.01 substitutions per nucleotide position.

Differentiation of species of the genus *Eggerthella*

A scheme for the differentiation of *Eggerthella* species is shown in Table 311.

TABLE 311. Phenotypic characteristics of *Eggerthella lenta*, *Eggerthella hongkonensis*, and *Eggerthella sinensis*[a,b,c]

Moore W.E.C., E.P. Cato and L.V. Holdeman. 1971. *Eubacterium lentum* (Eggerth) Prévot 1938: emendation of description and designation of the neotype strain. Int. J. Syst. Bacteriol. *21*: 299–303.

List of species of the genus *Eggerthella*

1. **Eggerthella lenta** Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 599[VP]

len′ta. L. fem. adj. *lenta* slow.

Cells from PYG broth cultures are 0.2–0.4 × 0.2–2.0 µm and occur singly and in pairs and short chains. Colonies on horse blood agar are 0.5–2.0 mm, circular, entire to erose, raised to low convex, translucent to semiopaque, dull to shiny, smooth, and sometimes with a mottled appearance. Most strains grow at 30 and 45°C; some grow at 25°C. Arginine enhances growth. Gas is not detected in PYG agar deep cultures. Ammonia is produced from arginine. Acid is not produced from sugars. Hydrogen sulfide is produced in the butt of TSI (triple-sugar iron) slants incubated anaerobically, but not in SIM medium. Catalase is produced by strains grown on agar medium containing 1%, w/v arginine. Hippurate is not hydrolyzed.

The metabolic end products from glucose are acetate with trace amounts of lactate or succinate. H_2 is not produced.

Source: human large intestine, feces, blood and clinical infections, primarily wounds and abscesses.

DNA G+C content (mol%): 61 (HPLC) for the type strain.

Type strain: ATCC 25559, CCUG 17323 A, CIP 106637, DSM 2243, JCM 9979, NCAIM B.01418, NCTC 11813.

Sequence accession no. (16S rRNA gene): AF292375.

Additional comments: arginine is degraded via the arginine dihydrolase pathway (Sperry and Wilkins, 1976a). The type strain contains cytochromes *a*, *b*, and *c* and a carbon monoxide-binding pigment (Sperry and Wilkins, 1976b).

Eggerthella lenta has been shown to transform a wide range of compounds, including steroids and lignans, primarily via dehydrogenases and dehydroxylase. Bile acids such as cholic and chenedeoxycholic acids are degraded by the action of 3α-, 7α-, and 12α- dehydrogenases; the 7α- activity is only demonstrable under anaerobic conditions (Hirano and Masuda, 1981; MacDonald et al., 1977). *Eggerthella lenta* strains also degrade corticosteroids (Bokkenheuser et al., 1977, 1979), linoleic acid, and related unsaturated long-chain fatty acids (Verhulst et al., 1986). The biological activity of the cardiac glycosides digitoxin and digoxigenin are destroyed by *Eggerthella lenta*-mediated reduction of a critical double bond (Dobkin et al., 1982; Robertson et al., 1986). Significant destruction of digoxigenin is thought to occur in 10% of treated patients owing to carriage of high concentrations of *Eggerthella lenta* in their gut microbiota (Chandrasekaran et al., 1987). *Eggerthella lenta* can participate in the metabolism of phyto-estrogens such as secoisolariciresinol diglucoside to produce the estrogen-like compounds enterodiol and enterolactone, which may play a role in the prevention of cancer, atherosclerosis, and diabetes (Clavel et al., 2005, 2006; Jin et al., 2007).

The gene encoding the tetracycline efflux pump, TetK, conferring resistance to this antimicrobial, has been detected in *Eggerthella lenta* (Roberts et al., 1991)

2. **Eggerthella hongkongensis** Lau, Woo, Woo, Fung, Wong, Chan, Tam and Yuen 2006, 2025[VP] (Effective publication: Lau 2004b, 255.)

hong.kong′en′sis. N.L. fem. adj. *hongkongensis* pertaining to Hong Kong, the city where the bacterium was discovered.

Cells are obligately anaerobic, nonsporing, nonmotile Gram-stain-positive coccobacilli which occur in chains. Colonies on blood agar are gray-white and 0.5 mm in diameter after a 48-h anaerobic incubation at 37°C. Catalase, arginine dihydrolase and β-glucosidase are produced, but production of alanine arylamidase, arginine arylamidase, leucine arylamidase, and lysine arylamidase is variable. Alkaline phosphatase, indole, and urease are not produced and nitrate is not reduced. Acid is not produced from glucose or other sugars.

Source: blood.

DNA G+C content (mol%): 61 (HPLC) for the type strain.

Type strain: HKU10, DSM 16106, JCM 14552, LMG 22124.

Sequence accession no. (16S rRNA gene): AY288517.

3. **Eggerthella sinensis** Lau, Woo, Woo, Fung, Wong, Chan, Tam and Yuen 2006, 2025[VP] (Effective publication: Lau 2004b, 255.)

sin′en′sis. N.L. gen. n. *sinae* of China; N.L. fem. adj. *sinensis* pertaining to China, the country where the bacterium was discovered.

Cells are obligately anaerobic, non-sporing, nonmotile, Gram-stain-positive, coccobacilli which occur in chains. Colonies on blood agar are gray-white, and 0.5 mm in diameter after a 48-h anaerobic incubation at 37°C. Catalase, arginine dihydrolase, arginine arylamidase and lysine arylamidase are produced but not alkaline phosphatase, indole, urease, or β-glucosidase. Nitrate is not reduced and acid is not produced from sugars.

Source: blood.

DNA G+C content (mol%): 65 (HPLC) for the type strain.

Type strain: HKU14, DSM 16107, JCM 14551, LMG 22123.

Sequence accession no. (16S rRNA gene): AY321958.

Genus VII. **Olsenella** Dewhirst, Paster, Tzellas, Coleman, Downes, Spratt and Wade 2001, 1802[VP]

Floyd E. Dewhirst and William G. Wade

Ol.sen.el′la. L. fem. dim. ending -*ella*; N.L. fem n. *Olsenella* of Olsen, named to honor Ingar Olsen, a contemporary Norwegian microbiologist who first described *Lactobacillus uli.*

Cells are small, **elliptical rods** which occur singly, in pairs or short chains. Nonsporeforming. Nonmotile. Gram-stain-positive. **Obligate anaerobes**. Glucose fermented to **acetate and lactate**. Does not produce catalase, urease or indole, or reduce nitrate.

DNA G+C content (mol%): 63–64 (HPLC).

Type species: **Olsenella uli** (Olsen, Johnson, Moore and Moore 1991) Dewhirst, Paster, Tzellas, Coleman, Downes, Spratt and Wade 2001, 1802[VP] (*Lactobacillus uli* Olsen, Johnson, Moore and Moore 1991, 263.).

Further descriptive information

The major fatty acid of the cell membrane is $C_{18:1}$ (*cis*9). Strains have been isolated from the human oral cavity (Dewhirst et al., 2001; Munson et al., 2004; Olsen et al., 1991; Siqueira et al., 2005), human bacteremia (Lau et al., 2004a), and cow rumen (GenBank AJ251324).

Enrichment and isolation procedures

Strains of *Olsenella* species have been recovered using agar media commonly used for the cultivation of anaerobes, such as Brain Heart Infusion, Peptone Yeast Glucose, and Fastidious Anaerobe Agar, supplemented with 5% horse or sheep blood. Specific enrichment procedures have not been reported for the genus. The growth of *Olsenella uli*, but not that of *Olsenella profusa*, is markedly stimulated by addition of Tween 80 (0.02%, v/v).

Maintenance procedures

Stock cultures of *Olsenella* species can be maintained under anaerobic conditions by weekly transfer on Blood Agar plates. Cultures can be stored by lyophilization or freezing at −80°C in Brain Heart Infusion Broth supplemented with 10% glycerol.

Differentiation of the genus *Olsenella* from other genera

Characters that differentiate *Olsenella* from closely related genera are shown in Table 307. *Olsenella* can be differentiated from *Atopobium*, *Cryptobacterium*, and *Denitrobacterium* by G+C content of the DNA, from *Adlercreutzia*, *Denitrobacterium*, *Eggerthella*, and *Slackia* by sugar fermentation, and from *Collinsella*, *Coriobacterium*, and *Eggerthella* by site of origin. Molecular methods, such as sequencing of the 16S rRNA gene, provide the most definitive identification.

Taxonomic comments

Prior to the use of 16S rRNA-based phylogenetic analysis, strains of species in the genus *Olsenella* were misclassified in the genera *Eubacteria* and *Lactobacillus* of the phylum *Firmicutes*. The genus *Olsenella* is now recognized as one of nine genera classified in the family *Coriobacteriaceae* in the phylum *Actinobacteria* (Dewhirst et al., 2001; Wade et al., 1999) as shown in Figure 421.

Using 16S rRNA gene sequence analysis, examination of oral strains in the Virginia Polytechnic Institute Anaerobe

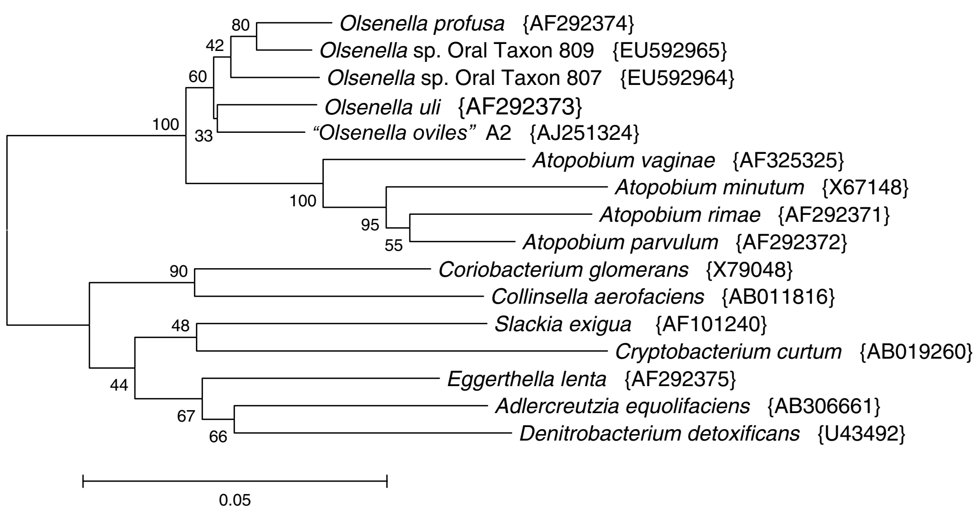

FIGURE 421. Neighbor-joining tree (Saitou and Nei, 1987) showing relationships between *Olsenella* species and representatives of other genera classified in the family *Coriobacteriaceae*. The optimal tree with the sum of branch length = 0.581 is shown. The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (1000 replicates) is shown next to the branches (Felsenstein, 1985). The tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. The evolutionary distances were computed using the Jukes–Cantor method (Jukes and Cantor, 1969) and are expressed as the number of base substitutions per site. All positions containing alignment gaps and missing data were eliminated only in pairwise sequence comparisons (pairwise deletion option). There were a total of 1491 positions in the final dataset. Phylogenetic analyses were conducted in MEGA4 (Tamura et al., 2007).

TABLE 312. Differential characteristics of *Olsenella uli* and *Olsenella profusa*[a]

Test	*O. uli* (48 strains)	*O. profusa* (2 strains)
Rapid ID 32A profile	2012 0337 05	4516 0537 05
Growth in PYG broth	Poor (1+)	Good (3–4+)
Growth stimulation by Tween 80	Marked	Slight
Arginine hydrolysis	+	−
Fermentation of:		
Arabinose	−	+
Mannitol	−	+
Melibiose	−	+
Raffinose	−	+
Colony morphology[b]	Raised, grey, semi-translucent	Pyramidal, cream, opaque

[a]Data from Olsen et al. (1991) and Dewhirst et al. (2001).

[b]After incubation for 7 d on Fastidious Anaerobe Agar.

Laboratory collection of W.E.C. Moore and L.V. Holderman Moore has identified two additional *Olsenella* species (F.E. Dewhirst, unpublished studies). These strains were designated Coccus D49 and *Lactobacillus* D19 by the Moores, and are now designated *Olsenella* sp. Oral Taxon 807 and *Olsenella* sp. Oral Taxon 809 as shown in Figure 421 and described in the Human Oral Microbiome Database (www.homd.org; Dewhirst et al., 2008). A rumen strain was isolated and informally called "*Atopobium oviles*" in a GenBank submission (AJ251324), but the name has not been formally published. Because the rumen strain has 97% mean similarity to *Olsenella uli* and *Olsenella profusa*, and only 93.5% mean similarity to *Atopobium* species, we would suggest the informal designation should be "*Olsenella oviles*". Several dozen clone sequences in GenBank, from a variety of sources, are greater than 90% similar to species in the genera *Olsenella* and *Atopobium*. Some of these clones come from environmental sources, but may represent bacteria shed from mammalian hosts.

Acknowledgements

Floyd E. Dewhirst was supported by NIH grant DE106937 from the National Institute of Dental and Craniofacial Research.

Differentiation of species of the genus *Olsenella*

Biochemical characteristics useful in distinguishing the species of genus are listed in Table 312. The two species are easily differentiated from one another by using Rapid ID32A anaerobe identification kits (bioMérieux) and on the basis of 16S rRNA gene sequences.

List of species of the genus *Olsenella*

1. **Olsenella uli** (Olsen, Johnson, Moore and Moore 1991) Dewhirst, Paster, Tzellas, Coleman, Downes, Spratt and Wade 2001, 1802[VP] (*Lactobacillus uli* Olsen, Johnson, Moore and Moore 1991, 263)

u'li. Gr. n. *oulon* the gums; N.L. gen. n. *uli* of the gum.

This description comes primarily from Olsen et al. (1991) with additional information from Dewhirst et al. (2001). Cells are small elliptical rods, which occur singly, in pairs, or short chains and may show central swellings. Nonmotile. Colonies on brain heart blood agar are 1–2 mm in diameter, raised or low convex, and entire after 5 d of anaerobic incubation.

Obligate anaerobe. Grows in Peptone Yeast extract Glucose Hemin vitamin K (PYG-HK) broth (Holdeman et al., 1977a). Growth is stimulated by Tween 80 (0.02%, v/v).

The major fermentation products from glucose are acetate and lactate with occasional minor amounts of succinate. Acid is produced from fructose, glucose, maltose, mannose, salicin, and sucrose, but not from amygdalin, erythritol, esculin, glycerol, inositol, mannitol, melezitose, melibiose, raffinose, rhamnose, sorbitol, or xylose. Indole is not produced and nitrate is not reduced. Negative reaction for bile-esculin, DNase, and hippurate hydrolysis. The Rapid ID32A profile is 2012 0337 05. The major cell wall fatty acid is $C_{18:1}$ (*cis*9).

Source: human gingival crevices of patients with periodontitis (Olsen et al., 1991) and from patients with endodontic infections (Siqueira et al., 2005). Has been recovered from human bacteremia (Lau et al., 2004a).

DNA G+C content (mol%): 64 (HPLC) for type strain.

Type strain: VPI D76D-27C, ATCC 49627, CCUG 31166, DSM 7084, JCM 12494, LMG 11480.

Sequence accession no. (16S rRNA gene): AF292373.

Additional comments: the species was previously designated *Lactobacillus* D01 in the Virginia Polytechnic Institute Anaerobe Laboratory collection of W.E.C. Moore and L.V. Holdeman Moore and initially named *Lactobacillus uli* by Olsen et al. (1991). The phenotypic description of the species

needs validation as some strains used in the description of *Lactobacillus uli* have been identified recently as belonging to other *Olsenella* species and to *Atopobium* species by 16S rRNA gene sequence analysis (Dewhirst, unpublished observation).

2. **Olsenella profusa** Dewhirst, Paster, Tzellas, Coleman, Downes, Spratt and Wade 2001, 1802^{VP}

pro.fus′a. L. adj. *profusus* profuse, referring to the good growth of the organism.

The description is based primarily on Dewhirst et al. (2001). Cells are short rods 0.6 × 0.8–2.0 µm, which occur singly or in chains. Nonmotile. After incubation for 7 d on FAA plates, colonies are approximately 1–1.3 mm in diameter, circular, entire, pulvinate to pyramidal, cream colored, and opaque when viewed under a plate microscope. Growth in broth media is good, and addition of Tween 80 does not significantly enhance growth.

Acetate and lactate are major end products of metabolism. Arabinose, cellobiose, fructose, glucose, lactose, maltose, mannitol, mannose, melibiose, raffinose, salicin, sucrose, and trehalose are fermented, but not melezitose, or rhamnose. Esculin is hydrolyzed, but not arginine or starch. Gelatin is not liquified meat is not digested. Does not produce catalase, indole, or H_2S or reduce nitrate.

Source: human subgingival plaque of patients with periodontitis (Dewhirst et al., 2001) and dental caries (Munson et al., 2004). Detected in endodontic infections (Rôças and Siqueira, 2005).

DNA G+C content (mol%): 64 (HPLC) for the type strain.

Type strain: VPI D315A-29, DSM 13989, CCUG 45371, CIP 106885, DSM 13989, JCM 14553.

Sequence accession no. (16S rRNA gene): AF292374.

Additional comments: the species was previously designated *Eubacterium* D52 in the Virginia Polytechnic Institute Anaerobe Laboratory Collection of W.E.C. Moore and L.V. Holderman Moore.

Genus VIII. **Slackia** Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 598^{VP}

William G. Wade and Floyd E. Dewhirst

Slack′ia. N.L. fem. n. named to honor Geoffrey Slack, distinguished British microbiologist and dental researcher.

Cells are Gram-stain-positive **cocci, coccobacilli, or short bacilli**, which are obligately **anaerobic**, nonmotile, and do not produce endospores. **Arginine is hydrolyzed**; catalase, urease, and indole are not produced and esculin is not hydrolyzed. **Acid is not produced from sugars**. Metabolic end products from glucose are either **acetate or not detectable**.

DNA G+C content (mol%): 60–64 (HPLC).

Type species: **Slackia exigua** Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 598^{VP}.

Further descriptive information

The predominant long chain cellular fatty acids in *Slackia faecicanis* have been shown to be $C_{16:0}$, $C_{16:1}$ (*cis*9), $C_{18:0}$, $C_{18:1}$ (*cis*9), and $C_{19:1}$ iso (*cis*9) (Lawson et al., 2005) but comparable data are not available for *Slackia exigua* or *Slackia heliotrinireducens*. *Slackia exigua* degrades arginine by the arginine deaminase pathway, as does *Cryptobacterium curtum*, another member of the family *Coriobacteriaceae* (Uematsu et al., 2006).

Strains corresponding to *Slackia exigua* were referred to as *Eubacterium* D6 in the Virginia Polytechnic Institute Anaerobe Laboratory collection of W.E.C. Moore and L.V. Holdeman Moore, "*Eubacterium* Cluster 2" (Wade et al., 1990) and "*Eubacterium* S-group" (Sato et al., 1993) prior to the formal description of the species, initially as "*Eubacterium exiguum*" (Poco et al., 1996). *Slackia exigua* is part of the human oral microbiota and has been associated with periodontitis (Moore et al., 1983), endodontic infections (Hashimura et al., 2001; Sato et al., 1993), and dentoalveolar abscesses (Downes et al., 2001; Wade et al., 1994). In patients with periodontitis, the species is particularly associated with deep pockets suggesting that this is its preferred habitat (Booth et al., 2004). In addition, patients with rapidly progressive periodontitis and refractory adult periodontitis have been shown to have raised antibody titers to *Slackia exigua*, suggesting a role in the pathogenesis of the disease (Smith and Wade, 1999). *Slackia exigua* has also been isolated from a case of bacteremia as part of a polymicrobial infection (Woo et al., 2004).

Ingestion of ragwort by grazing animals can lead to death due to hepatic cirrhosis up to 2 years after ingestion (Muth, 1968). However, sheep are resistant to the toxic substances in ragwort while horses and cattle are susceptible. It is the presence of *Slackia heliotrinireducens* and other as yet uncharacterized bacteria in the sheep rumen that is thought to confer resistance by degrading the pyrrolizidine alkaloids responsible for toxicity (Craig et al., 1992). *Slackia heliotrinireducens* can degrade heliotrine and lasiocarpine but not jacobine or seneciphylline (Hovermale and Craig, 2002).

Enrichment and isolation procedures

Slackia exigua has been successfully grown on Brain Heart Infusion agar and Fastidious Anaerobe Agar, both supplemented with 5% horse or sheep blood, while *Slackia faecicanis* can be cultured on Bacteroides agar (Holdeman et al., 1977a). Strains of all species are slow-growing, but *Slackia exigua* is particularly slow, forming colonies no greater than 1 mm in diameter, even after prolonged incubation.

Enrichment for *Slackia heliotrinireducens* can be achieved by culture in sheep rumen contents supplemented with heliotrine (2 mg/ml) and chloral hydrate (0.2 mg/ml) in an atmosphere of H_2-CO_2 (4:1) for 24–30 h, followed by successive subcultures

in a medium containing 30% rumen fluid, 0.2% heliotrine, and salts. Dilutions from the final enrichment can be cultured in roll tubes in medium containing 30% rumen fluid, 0.1% heliotrine, salts, and 1% (w/v) Ionagar (Oxoid no. 2). After incubation for 7–8 d at 38°C, colonies resembling those of *Slackia heliotrinreducens* can be selected and subcultured (Lanigan, 1976). Methods for assay of the alkaloids and their metabolites are given by Lanigan and Smith (1970).

Maintenance procedures

Strains can be maintained on Blood Agar plates, or tryptone-yeast-mineral salts (TYM; Lanigan, 1976) for *Slackia heliotrinireducens*, incubated anaerobically at 37°C, and subcultured weekly. Lyophilization of cultures is recommended for long-term storage, although strains have been successfully stored at −70°C in Brain Heart Infusion Broth + 10% glycerol.

Differentiation from closely related taxa

A simple scheme for the differentiation of the three *Slackia* species, primarily based on a commercial kit for the identification of anaerobic bacteria, is shown in Table 313. Given the slow growth and general unreactivity of members of this group and related *Actinobacteria*, molecular methods such as sequencing of the 16S rRNA gene are recommended for unambiguous identification.

Taxonomic comments

The phylogenetic relationship between the genus *Slackia* and related genera within the family *Coriobacteriaceae* can be seen in the tree constructed from 16S rRNA gene comparisons in Figure 420.

TABLE 313. Differential characteristics of *Slackia* species[a,b]

Characteristic	*S. faecicanis*	*S. exigua*	*S. heliotrinireducens*

Acknowledgements

Martin Slayne, Sarah Cheeseman, Sarah Hiom, Dave Dymock, and Julie Downes are thanked for their scientific and technical contributions to the work described in this chapter. Paul Lawson is thanked for discussions clarifying characteristics of *Slackia faecicanis.*

List of species of the genus *Slackia*

1. **Slackia exigua** (*Eubacterium exiguum* Poco, Nakazawa, Ikeda, Sato, Sato and Hoshino 1996) Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 598[VP]

ex.igu′a. L. fem. adj. *exigua* scanty, small, referring to the scanty or poor growth of the organism.

Cells are short Gram-stain-positive rods that are obligately anaerobic, nonmotile, and nonsporing. Individual cells are 0.5 × 1.0 mm, and the cells occur singly or in clumps. Sometimes cells from older cultures stain Gram-negative. On BHI-blood agar plates, the cells form minute, circular, convex, translucent colonies that are less than 1 mm in diameter even after prolonged incubation in an anaerobic glove box. Growth in broth media is poor with or without carbohydrates but is moderately enhanced in the presence of 5% bovine serum, 0.2% lysine, or 0.2% arginine. Hemolysis does not occur around colonies on BHI blood agar plates. The cells are inert in most biochemical tests. Starch and esculin are not hydrolyzed, and nitrate is not reduced. Does not liquefy gelatin. Catalase-, indole- and urease-negative. Ammonia is produced from arginine. All strains are nonfermentative and do not utilize adonitol, amygdalin, arabinose, cellobiose, erythritol, esculin, fructose, galactose, glucose, glycogen, inositol, lactose, maltose, mannitol, mannose, melezitose, melibiose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose, or xylose. No detectable metabolic end products are produced in peptone-yeast extract medium supplemented with glucose or peptone-yeast extract-glucose broth.

Source: human necrotic pulp samples, periapical infections, and acute dento-alveolar abscesses.

DNA G+C content (mol%) of the type strain: 60 (HPLC).

Type strain: S-7, ATCC 700122, CIP 105133, JCM 11022.

Sequence accession no. (16S rRNA gene): AF101240.

2. **Slackia heliotrinireducens** Wade, Downes, Dymock, Hiom, Weightman, Dewhirst, Paster, Tzellas and Coleman 1999, 599[VP]

he.li.o.trin.i.re.duc.ens. N.L. n. *heliotrinum* derived from heliotrine, a pyrrolizidine alkaloid; L. part. adj. *reducans* leading back, bringing back and in chemistry converting to a different oxidation state; N.L. part. adj. *heliotrinireducens* referring to the organism's ability to bring about oxidative cleavage of the heliotrine molecule.

Cells are cocci (0.5–0.7 µm in diameter), that occur in pairs, in small clusters and short chains. Subsurface colonies in TYM agar are lenticular with an entire margin and smooth surface. After incubation for 7–10 d, colonies are 0.6–0.8 mm

in diameter, grayish-white, and translucent. Surface colonies are 1–2 mm in diameter, effuse, colorless, and transparent with an entire edge. Optimum growth temperature is between 38°C and 42°C with some growth between 30°C and 46°C. Maximal growth occurs between pH 6.5 and 7.0 with some growth between pH 6.2 and 7.2. The presence of 2% NaCl is inhibitory to growth in TYM medium. Growth is enhanced by arginine (10–25 mM), but not by 1% (v/v) serum or 1% (v/v) Tween 80, while glycine (40 mM) is inhibitory. Addition of alanine, glutamate, histidine, ornithine, proline, serine, threonine, and combinations of alanine plus ornithine or alanine plus proline do not affect growth. Ammonia is formed from adenine, arginine, tryptone, yeast extract, and uracil. Nitrates are completely reduced to ammonia if sufficient electron donor (H_2 or formate) is present. Sulfates are not reduced. Creatinine is not hydrolyzed. Does not form gas in TYM-agar medium.

Only a trace of acetate is detected in PY-glucose culture by gas chromatographic analysis. Small amounts of H_2 and CO_2 are produced. Fumarate is reduced to succinate if formate or H_2 is present. Lactate, malate, and pyruvate are not metabolized. Pyrrolizidine alkaloids (europine, heleurine, heliotrine, lasiocarpine, and supinine) are reduced to 1-methylene derivatives in the presence of H_2 or formate (electron donors). Some macrocyclic diesters are metabolized, but more slowly than the monoesters. Anacrotine, cynaustraline, heliotridine, retrorsine, and sarracine are not metabolized. A *c*-type cytochrome is present in ultrasonic extracts of cells. Growth is inhibited in media containing 10 units/ml penicillin.

Source: sheep rumen.

DNA G+C content (mol%) of the type strain: 61 (HPLC).

Type strain: RHS1, ATCC 29202, NCTC 11029, CCUG 47954, JCM 14554, DSM 20476.

Sequence accession no. (16S rRNA gene): AF101241.

3. **Slackia faecicanis** Lawson, Greetham, Gibson, Giffard, Falsen and Collins 2005, 1245[VP]

fae.ci.ca′nis. L. n. *faex*, *faecis* feces; L. gen. n. *canis* dog; N.L. gen. n. *faecicanis* from dog feces.

Cells are short Gram-stain-positive rods (0.5 × 1–2 µm). Colonies after a 48-h anaerobic incubation at 37°C are 1–2 mm in diameter, translucent to gray, with an uneven surface with irregular edges. Strains are obligate anaerobes. Nitrate is reduced to nitrite. Catalase and indole are not produced. Acid is not produced from glucose, lactose, maltose, mannose, mannitol, melibiose, ribose, starch, or sucrose. Using the API Rapid ID32A system, only arginine dihydrolase is positive. The predominant long-chain cellular fatty acids consist of $C_{16:0}$, $C_{16:1}$ (*cis*9), $C_{18:0}$, $C_{18:1}$ (*cis*9), and $C_{19:1}$ iso (*cis*9).

Source: the primary habitat is unknown but is probably the intestinal tract of the dog.

DNA G+C content (mol%) of the type strain: 61 (HPLC).

Type strain: 5WC12, CCUG 48399, CIP 108281, JCM 14555.

Sequence accession no. (16S rRNA gene): AJ608686.

Class IV. **Nitriliruptoria** class. nov.

WOLFGANG LUDWIG, JEAN EUZÉBY AND WILLIAM B. WHITMAN

Ni.tri.li.rup.tor′i.a. N.L. masc. n. *Nitriliruptor* type genus of the type order; suffix *-ia* ending to denote a class; N.L. pl. neut. n. *Nitriliruptoria* the *Nitriliruptorales* class.

This class is formed by elevation of the subclass *Nitriliruptoridae* Kurahashi et al. 2010, which was delineated on the basis of 16S rRNA gene sequence analyses and the distinctive phyletic lineage of the type order.

Type order: **Nitriliruptorales** Sorokin, van Pelt, Tourova and Evtushenko 2009, 252[VP].

Reference

Kurahashi, M., Y. Fukunaga, Y. Sakiyama, S. Harayama and A. Yokota. 2010. *Euzebya tangerina* gen. nov., sp. nov., a deeply branching marine actinobacterium isolated from the sea cucumber *Holothuria edulis*, and proposal of *Euzebyaceae* fam. nov., *Euzebyales* ord. nov. and *Nitriliruptoridae* subclassis nov. Int. J. Syst. Evol. Microbiol. *60*: 2314–2319.

Order I. **Nitriliruptorales** Sorokin, van Pelt, Tourova and Evtushenko 2009, 252[VP]

The Editorial Board

Ni.tri.li.rup.tor.a′les. N.L. masc. n. *Nitriliruptor* type genus of the order; suffix -*ales* ending to denote an order; N.L. fem. pl. n. *Nitriliruptorales* the order of the genus *Nitriliruptor*.

Description is the same as the family *Nitriliruptoraceae*.

Type genus: **Nitriliruptor** Sorokin, van Pelt, Tourova and Evtushenko 2009, 251[VP].

Reference

Sorokin, D.Y., S. van Pelt, T.P. Tourova and L.I. Evtushenko. 2009. *Nitriliruptor alkaliphilus* gen. nov., sp. nov., a deep-lineage haloalkaliphilic actinobacterium from soda lakes capable of growth on aliphatic nitriles, and proposal of *Nitriliruptoraceae* fam. nov. and *Nitriliruptorales* ord. nov. Int. J. Syst. Evol. Microbiol. *59*: 248–253.

Family I. **Nitriliruptoraceae** Sorokin, van Pelt, Tourova and Evtushenko 2009, 251[VP]

The Editorial Board

Ni.tri.li.rup.to.ra.ce′a.e. N.L. masc. n. *Nitriliruptor* type genus of the family; suffix -*aceae*, ending to denote a family; N.L. fem. pl. n. *Nitriliruptoraceae* the family of the genus *Nitriliruptor*.

Rods that stain Gram-positive. **Aerobic heterotrophs with the ability to degrade organic nitriles** as well as organic acids and sugars. **Alkaliniphilic and moderately salt-tolerant**. The description is otherwise the same as the type genus.

Type genus: **Nitriliruptor** Sorokin, van Pelt, Tourova and Evtushenko 2009, 251[VP].

Genus I. **Nitriliruptor** Sorokin, van Pelt, Tourova and Evtushenko 2009, 251[VP]

The Editorial Board

Ni.tri.li.rup′tor. N.L. n. *nitrilum* nitrile, nitrile group; L. masc. n. *ruptor* breaker; N.L. masc. n. *nitriliruptor* nitrile-breaker.

Short rods that **stain Gram-positive**. Aerobes that **utilize short-chain organic acids, amides, and aliphatic nitriles** as energy and carbon sources. The cell envelopes contain *meso*-diaminopimelate and saturated C_{14}–C_{16} fatty acids.

DNA G+C content (mol%): 70.8 (T_m).

Type species: **Nitriliruptor alkaliphilus** Sorokin, van Pelt, Tourova and Evtushenko 2009, 251[VP].

Further descriptive information

This description of the genus is based upon a single isolate of a single species and must necessarily be preliminary. Cells are short rods (0.4 × 1.5–3.0 µm) and nonmotile. Colonies develop very slowly over a period of 1 month and are flat, colorless, and spreading. The cells stain Gram-positive and contain alanine,

glutamate, and *meso*-diaminopimelate in a 2:1:1 molar ratio. Small amounts of other amino acids as well as the sugars glucose, galactose and glycerol are also present. Fatty acids include $C_{16:0}$ (19%), C_{14} (17%), $C_{16:1}$ ω7 (16%), $C_{14:0}$ (13%), C_{16} (8%), $C_{17:1}$ ω8 (5%), and $C_{18:1}$ ω9 (4%).

Growth is aerobic, and anaerobic growth on sugars with or without nitrate as an electron acceptor is not observed. Isobutyronitrile is completed degraded as a sole carbon and nitrogen source. Other nitriles utilized include propionitrile, butyronitrile, valeronitrile, and capronitrile, but not acetonitrile. Simple monocarboxylic and dicarboxylic organic acids, pyruvate, malate, fumarate, and citrate are also utilized. Sugars and sugar alcohols are utilized, including D-glucose, D-fructose, maltose, D-mannose, melezitose, α,α-trehalose, sucrose, D-arabinose, inositol, cellobiose, and glycerol. Yeast extract and peptone also support slow growth.

Isolated from a soda lake, the pH optimum and range are 9.0–9.4 and 8.4–10.4, respectively. The NaCl optimum and range are 0.2–0.3 M and 0.1–2.0 M, respectively. A mesophile, the temperature optimum is 32°C.

The type species was isolated from an isobutyronitrile-degrading consortium initiated from soda lake sediments of the Kulunda Steppe, Altai, Russia in pH 10 medium containing a total Na concentration of 0.6 M (Sorokin et al., 2007). Environmental clones with ~95 % sequence similarity have been isolated from sediments of other soda lakes and from saline and other soils.

List of species of the genus *Nitriliruptor*

1. **Nitriliruptor alkaliphilus** Sorokin, van Pelt, Tourova and Evtushenko 2009, 251[VP]

al.ka.li′phi.lus. N.L. n. *alkali* soda ash; Gr. adj. *philos* loving; N.L. adj. *alkaliphilus* alkali-loving.

The description is the same as for the genus.

DNA G+C content (mol%): 70.8 (T_m).

Type strain: ANL-iso2, DSM 45188, NCCB 100119, UNIQEM U239.

Sequence accession no. (16S rRNA gene): EF422408.

THE EDITORIAL BOARD

Eu.ze′by.a. N.L. fem. n. *Euzebya* named for Jean Paul Marie Euzéby, a French microbiologist who has contributed significantly to microbial systematics, including the Latinization of microbial names.

Rods that stain Gram-positive and do not form endospores. Aerobic chemo-organotrophs, oxidase- and catalase-positive. **Sodium chloride is required** for growth. **MK-9(H_4)** is the predominant menaquinone. The cell envelopes contain ***meso*-diaminopimelate, rhamnose, and galactose.** The major fatty acids are $C_{16:1}$ ω7*c*, $C_{16:0}$, and $C_{17:1}$ ω8*c*. The major polar lipid is phosphatidylglycerol.

DNA G+C content (mol%): 68.3 (HPLC).

Type species: **Euzebya tangerina** Kurahashi, Fukunaga, Sakiyama, Harayama and Yokota 2010, 2318[VP].

Further descriptive information

This description of the genus is based upon a single isolate of a single species and must necessarily be preliminary. Cells are rods (0.6–0.8 × 1.5–6.0 µm) and nonmotile. They stain Gram-positive and do not form endospores. Colonies develop very slowly over a period of 5 weeks and are pulvinate with an entire edge, tangerine in color, nearly opaque, and have a hard texture. The cells wall contains alanine, glutamate, and *meso*-diaminopimelate in a 2:1:1 molar ratio as well as the sugars rhamnose and galactose. Fatty acids include $C_{16:1}$ ω7*c* (35%), $C_{16:0}$ (19%), $C_{17:1}$ ω8*c* (18%), $C_{18:1}$ ω9*c* (8%), $C_{17:0}$ (5%), and 10-methyl $C_{17:0}$ (4%). The predominant menaquinone is MK-9(H_4).

Growth is aerobic, and nitrate is not reduced. Grows on complex media with peptone and yeast extract as carbon sources, such as marine agar or broth 2216 and TYSW medium (2 g tryptone and 1 g yeast extract in 1 l artificial seawater). Also assimilates L-arabinose and melibiose, but not amygdalin, D-glucose, inositol, D-mannose, rhamnose, sucrose, and sorbitol. Positive for hydrolysis of gelatin and urea and production of catalase, oxidase and acetoin. Negative for the production of β-galactosidase, arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, tryptophan deaminase, H_2S, and indole. Unable to utilize citrate.

Isolated from a marine source, the NaCl range for growth is 0.5–12%. The temperature optimum and range are 20–28°C and >10 and <40°C, respectively. The pH range is 7–9. Stock cultures are maintained in marine broth 2216 with 5% DMSO at −80°C.

The type species was isolated from the abdominal epidermis of a sea cucumber, *Holothuria edulis*, which had been collected from the coast of Aka Island, Okinawa prefecture, Japan, at a depth of 6 m (Kurahashi and Yokota, 2004; Valenzuela-Encinas et al., 2009). Environmental clones with greater than ~98% sequence similarity have been isolated from dolomite rock (Horath and Bachofen, 2009), haloalkaline soil (Valenzuela-Encinas et al., 2009), and anthracene-contaminated soils.

Class V. **Rubrobacteria** class. nov.

KEN-ICHIRO SUZUKI

Ru.bro.bac.te′ri.a. N.L. masc. n. *Rubrobacter* type genus of the type order; suff. *-ia* ending to denote a class; N.L. pl. neut. n. *Rubrobacteria* the *Rubrobacterales* class.

The subclass *Rubrobacteridae* was established by Rainey et al. (1997) for the phylogenetic construction of the hierarchical structure of the class *Actinobacteria*. At the time, only the genus *Rubrobacter* was known, and the subclass contained the single order *Rubrobacterales*, which was represented by the family *Rubrobacteraceae* for the genus *Rubrobacter*. Although the genus *Thermoleophilum* had already been described (Zarilla and Perry, 1984), it was not included in the study. Later, the genus *Thermoleophilum* was reported to be the member of the subclass *Rubrobacteridae* (Yakimov et al., 2003). Almost at the same time, the new genera *Conexibacter* (Monciardini et al. 2003) and *Solirubrobacter* (Singleton et al. 2003) were described. Although their classification at the higher ranks was discussed, a formal recommendation was not made. In 2005, the *Manual* tentatively assigned the genera *Conexibacter*, *Solirubrobacter*, and *Thermoleophilum* to the family *Rubrobacteraceae*, which was the only family validly published at the time (Appendix 2 of Garrity et al., 2005). Stackebrandt (2004, 2005) reanalyzed the relationship of these genera to the subclass *Rubrobacteridae* and proposed the families *Conexibacteraceae*, *Solirubrobacteraceae* and *Thermoleophilaceae* with the emendation of the subclass *Rubrobacteridae* and the family *Rubrobacteraceae*. The results of Stackebrandt (2004, 2005) were considered in the later study for reconstruction of the class *Actinobacteria* based on the 16S rRNA gene sequences (Zhi et al., 2009). Almost at the same time, Reddy and Garcia-Pichel (2009) proposed the orders *Thermoleophilales* and *Solirubrobacterales*, which reflected the low sequence similarity of the 16S rRNA genes between these families and *Rubrobacter* spp.

Lastly, Ludwig et al. (2012) found little phylogenetic or phenotypic evidence for an association between *Rubrobacter* and the orders *Thermoleophilales* and *Solirubrobacterales*. For this reason, they proposed the classification of these groups into the novel classes *Rubrobacteria* and *Thermoleophilia*.

The rRNA gene signatures for the families of the classes *Rubrobacteria* and *Thermoleophilia* are given in Table 314 and differential signatures are given in Table 315.

Type order: **Rubrobacterales** Rainey, Ward-Rainey and Stackebrandt 1997, 483[VP] emend. Zhi, Li and Stackebrandt 2009, 593.

Ru.bro.bac′ter. L. adj. *ruber* red; N.L. masc. n. *bacter* equivalent of the Gr. neut. n. *baktron* a rod; N.L. masc. n. *Rubrobacter* red rod.

Gram-stain-positive irregular rods. Nonmotile and non-sporforming. Cells are generally 0.8–1.0 by 1.0–4.0 µm. Cells in old culture present shorter coccoid form. Aerial mycelia are not formed. **Obligately aerobic**. Catalase and cytochrome oxidase reactions are positive. Nitrite is produced from nitrate.

Where known, the **diamino acid of the cell-wall peptidoglycan is L-lysine** (cell-wall type A3α). However, there is no data for the species *Rubrobacter taiwanensis*. Predominant respiratory quinone is menaquinone with eight isoprene units (**MK-8**). The polar lipids consist of phospholipids including diphosphatidylglycerol, phosphatidylglycerol and one phosphoglycolipid. Some additional phospholipids and glycolipids are also found. Predominant cellular fatty acids are internal branched acids such as **12-methyl hexadecanoic acid and/or 14-methyl octadecanoic acid**. Mycolic acid is not present.

DNA G+C content (mol%): 65–69 (HPLC, T_m).

Type species: **Rubrobacter radiotolerans** (Yoshinaka, Yano and Yamaguchi 1973) Suzuki, Collins, Iijima and Komagata 1989, 93^{VP} (Effective publication: Suzuki, Collins, Iijima and Komagata 1988, 38.).

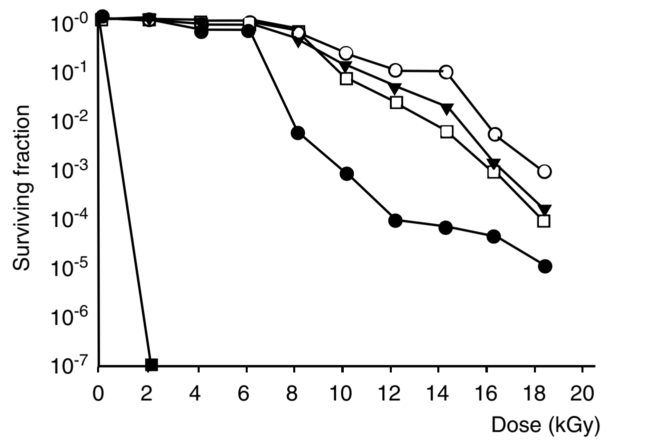

FIGURE 422. Gamma-radiation resistance of species of the genus *Rubrobacter* (from Chen et al., 2004). *Rubrobacter radiotolerans* DSM 5868 (○); *Rubrobacter taiwanensis* BCRC 17173 (▼); *Rubrobacter xylanophilus* DSM 9441 (●): *Deinococcus radiodurans* DSM 20539 (□); *Escherichia coli* K-12 (■).

Further descriptive information

Tolerance to γ-irradiation is the most distinctive feature of the genus *Rubrobacter*, although this characteristic is not specified in the original description of the genus (Yoshinaka et al., 1973). All the described species of the genus *Rubrobacter* show resistance against gamma-radiation (Chen et al., 2004). In addition, the species described so far are moderate thermophiles growing optimally at 46–60°C.

Resistance to γ-irradiation. The type strain of *Rubrobacter radiotolerans*, the type species of the genus, was isolated from a hot spring with high background radiation, and the sample was exposed to γ-radiation prior to isolation. Later, the strain was found to be extremely radiotolerant, comparable to that of species of the genus *Deinococcus* which is also strongly radiatino resistant. For *Rubrobacter radiotolerans*, the shoulder dose, or the dose at which killing is first observed, of exponentially growing cells is 6 kGy, and the D_{10}, or the dose necessary for 10% survival, is 10.0 kGy in phosphate buffer on aerated condition (Ito et al., 1983). The strains of the other species are also extremely radiotolerant, similar to that of *Deinococcus* species whose radiotolerance is well known (Figure 422, from Chen et al., 2004; Ferreira et al., 1999; Saito et al., 1994).

Cellular fatty acids. Strains of the genus *Rubrobacter* contain a large proportion of fatty acids which have methyl branch at a characteristic position in the middle of acyl chain. Such branched fatty acids widely distributed in actinobacteria are 10-methyl acids. 10-Methyl acids are known as the derivatives of corresponding monounsaturated fatty acids such as oleic acid

($C_{18:0}$ ω9). The predominant fatty acids of the genus *Rubrobacter* are 12-methyl hexadecanoic acid (12-Me $C_{16:0}$) and 14-methyl octadecanoic acid (14-Me $C_{18:0}$). Their methyl branch is at a unique position, the 5th carbon from the omega or apolar end of the fatty acid. They are possibly biosynthesized by methylation of corresponding unsaturated acids, namely $C_{16:0}$ ω5 and $C_{18:0}$ ω5, respectively (Suzuki et al., 1993). These unsaturated acids are of the same series of fatty acids with double bonds between the 4th and 5th carbons from the omega end of the acyl chain. Furthermore, 12-Me $C_{16:0}$ is the predominant fatty acid for *Rubrobacter radiotolerans* (Suzuki et al., 1988), and 14-Me $C_{18:0}$ is that for *Rubrobacter taiwanensis* and *Rubrobacter xylanophilus*. The optimal growth temperature of *Rubrobacter radiotolerans* is 45°C, in contrast to 60°C for the latter two species. It is expected that strains growing at higher temperatures have longer cellular fatty acids. Suzuki et al. (1988) reported that $C_{19:0}$ anteiso and $C_{17:0}$ 2-OH were also present in the cells of *Rubrobacter radiotolerans*,. However, these fatty acids were not found by subsequent investigators (Carreto et al., 1996; Chen et al., 2004). It will be interesting if there is found to be some relationship between these distinctive fatty acids and radiation resistance.

Enrichment and isolation procedures

The three species of the genus *Rubrobacter* are characterized by their strong resistance to γ-irradiation. The type strain of *Rubrobacter radiotolerans* was isolated from a sample pre-treated with 1.7 kGy irradiation by Cs^{137} for 5 h (Yoshinaka et al., 1973). Furthermore, the samples for isolation were collected at a radioactive hot spring. Although *Rubrobacter radiotolerans* is a moderate thermophile, it grows slowly. The characteristic pink colonies were picked up after 1-week cultivation at 37°C on an agar plate on which the irradiated sample was spread. Some faster-growing bacteria appeared after only a few days prior to the small pink colonies of the genus *Rubrobacter*.

The strains of the other two species were isolated from samples without radiation pretreatment and background radioactivity. These *Rubrobacter* strains were isolated from samples incubated at 50°C for growth of moderate thermophiles. In general, the isolation procedure involved spreading samples on agar plates and incubating at 50°C for 5–7 d. Pink colonies that appear slowly are picked (Carreto et al., 1996; Chen et al., 2004).

The strains of the genus *Rubrobacter* grow on various media, such as nutrient agar, tryptic soy broth, R medium, and *Thermus* medium. *Thermus* medium gives the best growth. The strains of the genus *Rubrobacter* are enriched by strong γ-irradiation and aerobic cultivation at 45–60°C.

Maintenance procedures

The strains of the genus *Rubrobacter* are preserved by freezing at lower than −70°C suspensions in *Thermus* medium containing 15% glycerol. Lyophilization in 10% skimmed milk containing 1% monosodium glutamate is also useful for long-term preservation and shipment.

Differentiation of the genus *Rubrobacter* from other genera

The genus *Deinococcus*, which also shows very strong radiation resistance, is classified in the phylum *Deinococci* and clearly differentiated by 16S rRNA gene sequences.

Taxonomic comments

Rubrobacter radiotolerans was firstly proposed by Yoshinaka et al. (1973) as a new species of the genus *Arthrobacter* because of the pleomorphic cell morphology, absence of acid production from sugars, and cell-wall peptidoglycan containing L-lysine. Later, Suzuki et al. (1988) proposed a new genus *Rubrobacter* for the species on the basis of the distinctive chemotaxonomic features in addition to the unusual physiological characteristics. The distinctiveness of this organism was further supported by phylogenetic analyses of the 16S rRNA gene sequences of the class *Actinobacteria* by Stackebrandt et al. (1997). The genus *Rubrobacter* was found to form a deep lineage, and it was classified outside of the subclass *Actinobacteridae*, which accommodated the order *Actinomycetales* in the class *Actinobacteria*. Stackebrandt et al. (1997) classified the single-genus taxon in the subclass *Rubrobacteridae*, order *Rubrobacteriales*, and family *Rubrobacteriaceae*. Later, the genera *Thermoleophilum* Yakimov et al. 2003 and *Solirubrobacter* Singleton et al. 2003 were classified in this subclass. Although the genus *Conexibacter* was closely related to *Solirubrobacter*, it was not included (Monciardini et al., 2003). Subsequently, these genera were reclassified into independent families, namely *Conexibacteraceae*, *Solirubrobacteraceae*, and *Thermoleophilaceae* (Stackebrandt 2004; Zhi et al. 2009), and novel orders, *Solirubrobacterales* and *Thermoleophilales*. The order *Solirubrobacterales* contains the families *Conexibacteraceae*, *Patulibacteraceae*, and *Solirubrobacter* (Reddy and Garcia-Pichel 2009). The order *Thermoleophilales* accommodates the family *Thermoleophilaceae*. In the absence of clear evidence of relatedness, these genera were finally reclassified in a novel class, *Thermoleophilia*, as well (Ludwig et al., 2012).

Currently, three species have been described in the genus *Rubrobacter*, and they share common chemotaxonomic, biochemical and physiological features. Because only one or two strains have been described for each species, the variability within species is not known. The species classification has also been confirmed by DNA relatedness studies (Chen et al., 2004).

Differentiation of the species of the genus *Rubrobacter*

Three species share many phenotypic and chemotaxonomic features, such as isoprenoid quinones and cell-wall peptidoglycan type (Table 316). Likewise, the cellular fatty acid profiles are very similar. Features that distinguish the species include the optimum growth temperature and a number of other physiological and biochemical characteristics (Table 316). The DNA relatedness and 16S rRNA gene sequence differences also strongly support the differentiation.

The common biochemical and physiological characteristics for the three species of the genus *Rubrobacter* are as follows. Positive reaction: catalase, cytochrome oxidase, β-glucosidase, β-galactosidase, growth in 5% NaCl and utilization of D-cellobiose, D-raffinose, D-trehalose, D-arabinose, D-fructose, D-mannose, lactose, L-glutamate, and pyruvate. Negative reaction: β-glucosidase, β-galactosidase, hydrolysis of starch, casein, cellulose, and tributyrin, and utilization of D-sorbitol. Characteristics variable among species are shown in Table 316.

TABLE 316. Phenotypic characteristics of *Rubrobacter* species[a,b]

Characteristic	1. *R. radiotolerans*[a]	2. *R. taiwanensis*[b]	3. *R. xylanophilus*[c]
Colony color	Reddish pink	Light pink	Light pink
Cell size (μm)	0.8–1.0 × 1.0–4.0	0.9–1.0 × 1.0–4.0	0.9–1.0 × 1.0–3.0

[a]Symbols : +, positive; −, negative; d, different in strains; nd, no data.

[b]The data are those of type strains except *Rubrobacter taiwanensis* (two strains) cited from Yoshinaka et al. (1973), Suzuki et al. (1988), Carreto et al. (1996), and Chen et al. (2004).

List of species of the genus *Rubrobacter*

1. **Rubrobacter radiotolerans** (Yoshinaka, Yano and Yamaguchi 1973, 2273[AL]) Suzuki, Collins, Iijima and Komagata 1989, 93[VP] (Effective publication: Suzuki, Collins, Iijima and Komagata 1988, 38.) (Basonym: *Arthrobacter radiotolerans* Yoshinaka, Yano and Yamaguchi 1973, 2273[AL]).

ra.di.o.to′le.rans. L. n. *radius* a beam or ray; N.L. pref. *radio*- pertaining to radiation; L. pres. part. *tolerans* tolerating; N.L. part. adj. *radiotolerans* (γ-ray) radiation-tolerating.

Gram-stain-positive irregular rod. Cells are 0.8–1.0 × 1.0–4.0 μm in size. Coccoid cells are often found in older cultures. Nonmotile. Colonies on nutrient agar are circular, smooth, entire convex or umbonate, glistening, opaque and reddish-pink in color. Colonies are 0.5–1.0 mm in diameter after 2 weeks, increasing in size to 4–5 mm after 4 weeks.

Xylose, arabinose, glucose, fructose, maltose and glycerol are utilized for growth. Galactose and mannose are weakly utilized. Sucrose, lactose, sorbitol and citrate are not utilized. Acid is not produced from any of carbon sources tested. Gelatin is not liquefied. Neither indole nor acetylmethylcarbinol is produced. Methyl red test negative. Ammonium sulfate is utilized as a sole nitrogen source.

Optimal temperature for growth is 46–48°C. Optimal pH for growth is 7.0–7.4. Growth is observed at 6% NaCl and lower but not at 10% NaCl in the culture medium.

The peptidoglycan structure is L-Lys–L-Ala. The cellular fatty acids are composed of more than 70% of 12-methyl branched octadecanoic acid, 12% of 16-methyl branched octadecanoic acid and 17% of 2-hydroxy heptadecanoic acid. Instead of these two acids, Carreto et al. (1996) report the presence of 14-Me $C_{18:0}$ and some long-chain alcohol.

The type strain was isolated from the radioactive hot spring at Misasa, Tottori, Japan after treatment of samples with γ-irradiation. Highly resistance to γ-irradiation. Shoulder dose of logarithmic growing cells is 6×10^5 rad and D_0 is 1×10^6 rad in phosphate buffer on aerated conditions.

Source of type strain: radioactive hot spring at Misasa, Tottori, Japan

DNA G+C content (mol%): 68 (HPLC).

Type strain: Yoshinaka strain P-1 = ATCC 51242 = CIP 106991 = DSM 5868 = IAM 12072 = IFO (now NBRC) 14777 = JCM 2153 = VKM Ac-1989.

Sequence accession no. (16S rRNA gene): D45058.

2. **Rubrobacter taiwanensis** Chen, Wu, Lin, Lu, Lin, Chang and Tsay 2004, 1853^VP

tai.wan.en′sis. N.L. masc. adj. *taiwanensis* of Taiwan, where the micro-organism was first isolated.

Cells are irregular short rods, 0.9–1.0 µm wide to 1.0–3.0 µm long. Colonies on *Thermus* medium grown at 60°C for 7 d are 1.6–2.2 mm in diameter, circular, convex, smooth, opaque, and light pink. The temperature range for growth is 30–70°C. Optimal growth is at 60°C. The pH range for growth is 6–11. Optimal growth is at pH 8.0. Growth occurs at NaCl concentrations of 5% and below in *Thermus* medium. Cytochrome oxidase and β-galactosidase are positive. Gelatin and DNA are hydrolyzed. The carbon sources utilized are shown in Table 316. 14-Methyl octadecanoic acid is the predominant cellular fatty acid (31–33%). Other fatty acids present are 12-methyl heptadecanoic acid and 12-methyl hexadecanoic acid. The strains of this species show strong resistance to γ-irradiation.

Source of type strain: thermally heated water/soil/mud samples of Lu-shan hot springs, Nantou, Taiwan.

DNA G+C content (mol%): 67.9–68.5 (HPLC).

Type strain: strain LS-293 = ATCC BAA-406 = BCRC 17173 = JCM 12932.

Sequence accession no. (16S rRNA gene): AF465803 (type strain).

3. **Rubrobacter xylanophilus** Carreto, Moore, Nobre, Wait, Riley, Sharp and Da Costa 1996, 463^VP

xy.la.no′phi.lus. N.L. n. *xylanum* xylan; Gr. adj. *philos* liking, friendly to; N.L. masc. adj. *xylanophilus* liking xylan.

Forms pleomorphic short rod-shaped cells that are 0.9–1.0 µm wide and 1.0–3.0 µm long; coccoid cells are also present. Colonies on *Thermus* medium incubated at 60°C for 7 d are 1.5–2.0 mm in diameter, circular, convex, smooth, opaque and light pink. Grows optimally at 60°C, and no growth is observed below 40°C and above 70°C. Optimal pH for growth is between 7.5 and 8.0, and no growth occurs below 6.0 and above 10.0. Growth occurs at NaCl concentrations of 6% and below in *Thermus* medium. β-Galactosidase-positive. Xylan is hydrolyzed. Growth occurs on various sugars, organic acids and amino acids (Table 316). The cell-wall peptidoglycan is L-Lys–L-Ala (type A3α). The major fatty acid is 14-methyl octadecanoic acid. Octadecanoic acid and by 12-methyl hexadecanoic acid are also present in cells grown at either 60°C or 45°C.

Source of type strain: thermally polluted run-off (temperature 50°C) from a carpet factory, Wilton, Wiltshire, UK.

DNA G+C content (mol%): 67.6 (T_m) for type strain.

Type strain: strain PRD-1 = CIP 105412 = DSM 9941 = NBRC 16129 = JCM 11954 = NBRC 100952.

Sequence accession no. (16S rRNA gene): CP000386.

Class VI. **Thermoleophilia** class. nov.

KEN-ICHIRO SUZUKI AND WILLIAM B. WHITMAN

Ther.mo.le.o.phi′li.a. N.L. neut. n. *Thermoleophilum* type genus of the type order; suff. *-ia* ending to denote a class; N.L. pl. neut. n. *Thermoleophilia* the *Thermoleophilales* class.

The class is defined on the basis of the 16S rRNA gene sequences (Table 314 and Table 315) and is supported by similarities in phenotypic properties. Although initial phylogenetic analyses described an affiliation of the families *Thermoleophilaceae*, *Conexibacteraceae*, *Patulibacteraceae*, and *Solirubrobacteraceae* within the order *Rubrobacterales* (Zhi et al., 2009), more recent analyses do not provide strong support for this association (Ludwig et al., 2012) (Figure 423). For this reason, these families were reclassified in their own class.

Type order: **Thermoleophilales** Reddy and Garcia-Pichel 2009, 91^VP^.

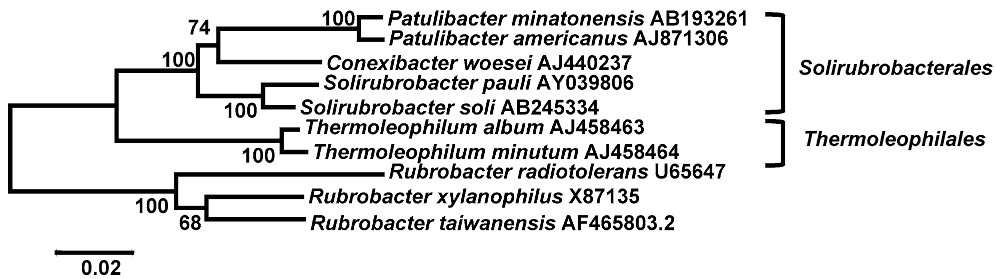

FIGURE 423. Phylogeny of the 16S rRNA genes of the representatives of the class *Thermoleophilia*. Members of the class *Rubrobacteria* serve as an outgroup. The phylogenetic tree was calculated with the Minimum Evolution algorithm of MEGA4. Evolution distance, calculated by the Kimura two-parameter model, is shown on the scale bar. Numbers represent the percentage bootstrap support for the indicated nodes based upon 1000 replicates.

Ther.mo.le.o.phi.la.ce′a.e. N.L. neut. n. *Thermoleophilum* type genus of the family; suff. *-aceae* ending to denote a family; N.L. fem. pl. n. *Thermoleophilaceae* the *Thermoleophilum* family.

Type genus: **Thermoleophilum** Zarilla and Perry 1986a, 355[VP] (Effective publication: Zarilla and Perry 1984, 290).

The family is defined on the basis of the 16S rRNA gene sequences (see Table 314) and supported by similarities in phenotypic properties. Members of the family are small, nonmotile rods which stain Gram-positive. Described species are moderately thermophilic aerobes that utilize *n*-alkanes, such as *n*-heptadecane, and a few other compounds as sole carbon sources.

Genus I. **Thermoleophilum** Zarilla and Perry 1986a, 355[VP] (Effective publication: Zarilla and Perry 1984, 290.)

Jerome J. Perry*

Ther.mo.le.o′phi.lum. Gr. n. *therme* heat; L. n. *oleum* oil; Gr. adj. *philos* loving; N.L. neut. n. *Thermoleophilum* heat- and oil-loving microbe.

Very small rods, 0.3–0.4 µm in diameter and 0.7–1.5 µm in length. Regular in shape. **No resting stage or endospores are observed**, Gram-stain-negative. **The major diamino acid in the cell wall is diaminopimelic acid.** Obligately **aerobic.** Nonmotile. **Optimum temperature for growth is 55–62°C** (minimum 45°C, maximum 70°C). pH optimum is 6–7.5. **Chemo-organotrophic, utilizing *n*-alkanes from 13 to 20 carbons in length; no other growth substrates are utilized.** Oxygen is terminal electron acceptor. Catalase-positive. Unpigmented. Growth is not stimulated by increased oxygen tension (shaking). **Generation time is 6–9 h.** Isolated from both thermal and non-thermal environments.

DNA G+C content (mol%): 68.8–70.4 (T_m).

Type species: **Thermoleophilum album** Zarilla and Perry 1986a, 355 (Effective publication: Zarilla and Perry 1984, 290.).

Further descriptive information

The sequence of bases in the 16S rRNA of *Thermoleophilum album* strain NM indicated that this micro-organism should be placed in a separate "phylum" within the *Eubacteria* (C. Woese, personal communication). Further study (Brown and Haas, 1997) provided evidence that the genus *Thermoleophilum* is related to and should be grouped with the green non-sulfur bacteria. A more recent study analyzing the morphology and genotype of the three strains of *Thermoleophilum album* and *Thermoleophilum minutum* indicated that the genus should be placed in the *Rubrobacter* subdivision of the *Actinobacteria* (Yakimov et al., 2003). These authors suggest that *Thermoleophilum* is a member of the group 2 subclass as the sole known culturable genus. On the basis of 16S rRNA gene sequence analysis, the type strains of *Thermoleophilum album* and *Thermoleophilum minutum* form a distinct lineage within the class *Actinobacteria*. Figure 424 shows a maximum-likelihood tree of selected members of the class *Actinobacteria*. The closest relatives of *Thermoleophilum album* and *Thermoleophilum minutum* are *Conexibacter woesei* (sequence similarities of 90.1% and 90.2%, respectively), *Solirubrobacter soli* (90% sequence similarity), *Solirubrobacter pauli* (sequence similarities of 89.8% and 89.9%, respectively), and *Patulibacter minatonensis* (90% sequence similarity). The genus *Thermoleophilum* is currently the only member of the family *Thermoleophilaceae*.

Six strains of *Thermoleophilum* have been isolated and all are small Gram-stain-negative rods that are regular in shape and occur singly. There is no evidence of flagella or motility (Zarilla and Perry, 1984). The major diamino acid in the cell walls is diaminopimelic acid, with lesser amounts of lysine or ornithine in some strains (Merkel et al., 1978a). Electron micrographs of thin sections reveal internal structures (Kennedy and Finnerty, 1975) that may be involved in alkane uptake and storage (Figure 425). Growth on agar surfaces is inconsistent and single colonies are rare. Growth is generally confluent, whitish, and flat. The optimum growth temperature is 60°C at pH 7.0. All strains are strict aerobes and grow solely on *n*-alkanes from *n*-tridecane to *n*-eicosane; optimal growth is on *n*-heptadecane (Zarilla and Perry, 1984, 1986b). Growth occurs on a mineral salts medium with *n*-alkane added at 0.1% (v/v) with NH_4 as preferred nitrogen source (Perry, 1992). Addition of growth factors (B vitamins, amino acids, etc.) does not increase growth rate or total cell yield. The total cell yield under putatively optimal conditions is 0.3–0.6 g/l. The generation time varies among strains and is 6–9 h. Addition of ^{14}C-labeled acetate to the growth medium (mineral salts + *n*-heptadecane) results in little incorporation of radiolabel into the resultant cell mass (<5% of total carbon). *Thermoleophilum* strains lack 2-oxoglutarate dehydrogenase and apparently do not utilize the tricarboxylic acid cycle in energy generation. They do possess the enzymes of the glyoxylate cycle (Weaver et al., 1987).

The DNA G+C content is 68.8–70.4 mol%. Thermal elution profiles of *Thermoleophilum* duplexes affirm that there are two species within the genus. Reassociation experiments with DNA from *Thermoleophilum* strains confirm that this genus has no relationship to *Thermus* sp., *Thermomicrobium roseum*, or thermophilic hydrocarbon-utilizing bacilli (Zarilla and Perry, 1987). *Thermoleophilum* has a novel respiratory quinone, a tetrahydrogenated menaquinone, 2-methyl-3-VI,VII-tetrahydroheptaprenyl-1,4-naphthoquinone (Collins et al., 1986). Although these organisms are strict aerobes, they do not respond favorably to increased aeration (Allgood and Perry, 1985). Examination of the enzymes involved in defense against toxic products of oxygen reduction, i.e. superoxide dismutase, peroxidase, and catalase, indicate that only catalase responds favorably to increased

*Deceased 17 May 2011.

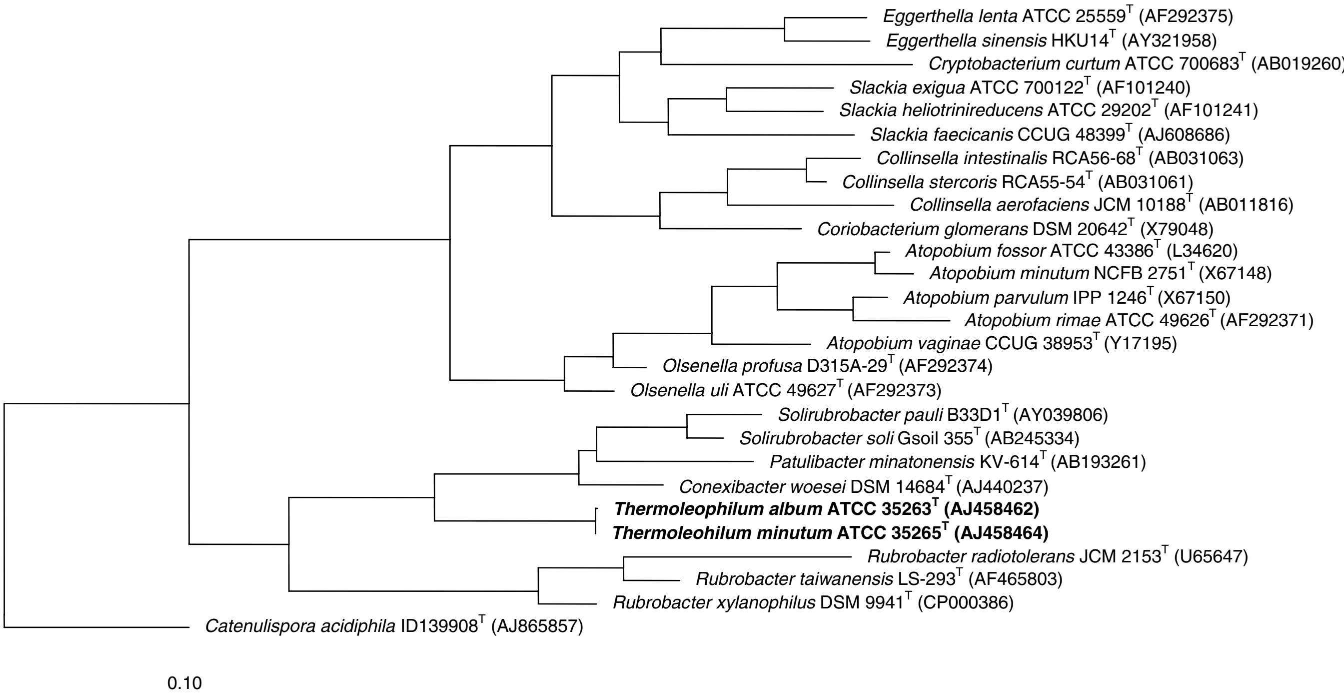

FIGURE 424. Phylogenetic analysis based on 16S rRNA gene sequences available from the EMBL data library (accession numbers are given in parentheses). The phylogenetic tree was constructed using the ARB software package (December 2007 version; Ludwig et al., 2004) and the corresponding SILVA SSURef 95 database (July 2008 version; Pruesse et al., 2007). Tree building was performed using the maximum-likelihood method with fastDNAml (Olsen et al., 1994) and no conservatory filter. Bar = 0.10 nucleotide substitutions per nucleotide position.

FIGURE 425. Electron micrograph of a thin section of *Thermoleophilum album* with clear areas containing stored *n*-alkane. Magnification = 31,000×.

oxygenation. Catalase was recovered and purified from *Thermoleophilum album* NM and is a heat-stable, manganese-containing enzyme with an M_r of 141,000 (Allgood and Perry, 1986). The manganese catalase gene from *Thermoleophilum album album* NM has been cloned and the nucleotide sequence has been determined (Phucharoen et al., 2001). The gene consists of 88 bp and encodes 294 amino acids with a molecular mass of 32,500 Da.

Electrophoretic mobility of selected enzymes on polyacrylamide gel indicated that enzymes from *Thermoleophilum* strains differ in mobility from equivalent enzymes in other species. An enzyme from each *Thermoleophilum* species was purified and characterized: malate dehydrogenase from *Thermoleophilum album* and isocitrate dehydrogenase from *Thermoleophilum minutum* (Novotny and Perry, 1990, 1991). The results indicate that the difference in mobility of these enzymes was related to some differences in amino acid composition and to the conformation of the protein. P RNA from *Thermoleophilum album* NM has been characterized and the RNase P is a type A ribonuclease (Brown and Haas, 1997).

The minimum antibiotic concentrations (μg/ml) that were inhibitory to all strains are as follows: chlortetracycline (25–50), neomycin (5–10), chloramphenicol (5–10), penicillin (5–25), and novobiocin (5–10).

Enrichment and isolation procedures

Six strains of *Thermoleophilum* have been obtained in axenic culture. These strains can be separated into two species: *Thermoleophilum album* and *Thermoleophilum minutum*. The six strains were isolated by enrichment from soil or mud obtained from across the USA (Table 317). Mud was added to a basal salts medium

TABLE 317. Source of the soil sample from which the obligately thermophilic strains of *Thermoleophilum* were isolated

Species	Source (in the USA)	Strain
T. album	Hot Springs, AR	HS-5^T
	Faywood Hot Springs, NM	NM
	Yellowstone National Park, WY	YS-3
	Roanoke Rapids, NC	RR-D
T. minutum	Yellowstone National Park, WY	YS-4^T
	Beaufort, NC	PTA-1

(Leadbetter and Foster, 1958) with *n*-heptadecane as sole carbon source (Merkel et al., 1978b). The enrichment was incubated at 60°C for 1–2 weeks and a transfer was made from media having visible turbidity to a sterile medium of the same composition. After several transfers in liquid medium, axenic cultures were obtained by streaking on a solid medium (2.0% agar) with *n*-heptadecane (0.2 ml) added in the cover of the inverted plate. *Thermoleophilum*, as the sole culturable genus in the subclass, serves as a prime example of the exacting culture conditions required for the isolation of a fastidious species from nature.

An exceedingly limited substrate range, high growth temperature, and sparse growth on a solid substrate offer ample evidence that culturing many "unculturable" microbes from nature is a difficult task.

Differentiation of the genus *Thermoleophilum* from other genera

The distinct and readily determinable characteristic of members of the genus *Thermoleophilum* is their restriction to growth with *n*-alkanes as substrate. Several characteristics that separate *Thermoleophilum* species from other Gram-stain-negative thermophiles are listed in Table 318. Under phase-contrast microscopy, *Thermomicrobium* cells appear pleomorphic, whereas *Thermus* cells are long, thin, regular rods and the cells of *Thermoleophilum* species are very small and regular in shape. The only other thermophilic hydrocarbon-utilizing aerophiles known are members of the genus *Bacillus* and can be distinguished by Gram-stain and production of endospores.

TABLE 318. Differential characteristics of Gram-stain-negative thermophilic rods

Characteristic	*Thermus* strains	*Thermomicrobium roseum*	*Thermoleophilum* strains
Peptidoglycan major diamino acid	Ornithine	None	Diaminopimelic acid
Cell morphology	Rods, 5–10 µm	Pleomorphic rods, 3–6 µm	Short rods, 0.7–1.5 µm
n-Alkane utilization	–	–	+
Growth on complex media	+	+	–
Growth on glucose	+	–	–
Generation time	20–60 min	5.5 h	6–9 h
Pigment	Cream, yellow, orange, pink	Pink	None
Respiratory quinone	MK-8	MK-8	MK-7(H_4)
Temperature range (°C)	60–70	70–75	55–65

List of species of the genus *Thermoleophilum*

1. **Thermoleophilum album** Zarilla and Perry 1986a, 355[VP] (Effective publication: Zarilla and Perry 1984, 290).

al′bum. L. neut. adj. *album* white.

Rod-shaped cells, 0.9 µm in length, nonmotile, nonsporeforming, Gram-stain-negative, aerobic, catalase-positive, and non-pigmented. Forms very small translucent to white colonies on agar surfaces. Grows solely with *n*-alkanes from 13 to 20 carbons in length at temperatures from 45 to 70°C. Addition of growth factors or increased aeration do not result in an increase in the growth rate or total cell yield.

Source: mud samples taken from both thermal and nonthermal environments.

DNA G+C content (mol%): 70.4 (T_m).

Type strain: HS-5, ATCC 35263.

Sequence accession no. (16S rRNA gene): AJ458462.

Further comments: additional strains of this species are NM (= ATCC 35266), YS-3 (= ATCC 35264), and RR-D (= ATCC 35267).

2. **Thermoleophilum minutum** Zarilla and Perry 1986b, 16[VP]

mi.nu′tum. L. neut. adj. *minutum* small, referring to cell size.

Rod-shaped cells, 1–1.5 µm in length. Nonmotile, nonsporeforming. Gram-stain-negative, aerobic, and catalase-positive. Nonpigmented. Forms small translucent to white colonies on agar surfaces. Grows solely with *n*-alkanes from 13 to 20 carbons in length at temperatures from 45 to 70°C. Addition of growth factors or increased aeration do not result in an increase in the growth rate or total cell yield. This species can be differentiated from *Thermoleophilum album* solely by thermal elution profile of DNA/DNA duplexes (Zarilla and Perry, 1986b).

Source: the type strain was isolated from a hot spring in Yellowstone National Park, USA.

DNA G+C content (mol%): 70.0 (T_m).

Type strain: YS-4, ATCC 35265.

Sequence accession no. (16S rRNA gene): AJ458464.

Further comments: an additional strain of this species is PTA-1 (= ATCC 35268), isolated from a mud sample from Beaufort, NC, USA.

Order II. **Solirubrobacterales** Reddy and Garcia-Pichel 2009, 91[VP]

WILLIAM B. WHITMAN AND KEN-ICHIRO SUZUKI

So.li.ru.bro.bac′te.ra.les. N.L. masc. n. *Solirubrobacter* type genus of the order; suff. *-ales* ending to denote an order; N.L. fem. pl. n. *Solirubrobacterales* the *Solirubrobacter* order.

The order *Solirubrobacterales* contains three families, *Solirubrobacteraceae*, *Conexibacteraceae*, and *Patulibacteraceae*. The order is defined on the basis of 16S rRNA gene sequence (see Table 314) and phenotypic similarities (Table 319). Although only a few genera have been described, cloning and sequencing of environmental DNA suggest that many more related taxa exist in nature. Currently described species are all Gram-stain positive, mesophilic and sometimes psychrotolerant, and contain *meso*-diaminopimelate as the diamino acid in their peptidoglycan.

Type genus: **Solirubrobacter** Singleton, Furlong, Peacock, White, Coleman and Whitman 2003, 489[VP].

TABLE 319. Characteristics of the genera in the order *Solirubrobacterales*[a]

Properties	*Solirubrobacter*[b]	*Conexibacter*[c]	*Patulibacter*[d]
Morphology (length in μm)	Rod (1.4)	Rod (0.9–1.2)	Rod (1.2–1.5)
Motility	Nonmotile	Motile	Motile
Temperature optimum (°C)	28–30	28–37	24–27
pH range	6–7.7	7–7.5	6–8
Oxidase	Negative	Positive	Negative
Major fatty acid	$C_{16:0}$ iso	$C_{18:1}$ ω9*c*	$C_{18:1}$ ω9*c*
Diamino acid in peptidoglycan	nd	*meso*-DAP	*meso*-DAP
Isoprenoid quinone	MK-7(H_4)	MK-7(H_4)	DMK-7, MK-7(H_4)

[a] Abbreviations: *meso*-DAP, *meso*-diaminopimelate; iso, iso methyl-branched; DMK, demethylmenaquinone; MK, menaquinone; nd, not determined.

Family I. **Solirubrobacteraceae** Stackebrandt 2005, 548^{VP} emend. Zhi, Li and Stackebrandt 2009, 594

William B. Whitman and Ken-ichiro Suzuki

So.li.ru.bro.bac′te.ra.ce.ae. N. L. masc. n. *Solirubrobacter* type genus of the family; suff. *-aceae* ending to denote a family; N. L. fem. pl. n. *Solirubrobacteraceae* the *Solirubrobacter* family.

Type genus: **Solirubrobacter** Singleton, Furlong, Peacock, White, Coleman and Whitman 2003, 489^{VP}.

The family is defined on the basis of 16S rRNA gene sequences (see Table 314) and supported by similarities in phenotypic properties. Members of the family are nonmotile rods which stain Gram-positive. Described species are aerobes that utilize many sugars and a few other compounds as sole carbon sources. For a comparison to related families, see the order description.

Genus I. **Solirubrobacter** Singleton, Furlong, Peacock, White, Coleman and Whitman 2003, 489^{VP}

William B. Whitman

So.li.ru.bro.bac′ter. L. n. *solum* soil; L. adj. *ruber* red; N.L. n. *bacter* the masculine equivalent of the Gr. neut. n. *bakterion* a rod; N.L. masc. n. *Solirubrobacter* a soil red rod.

Gram-stain positive, **rod** of medium length. **Nonmotile.** Spores are not formed. **Aerobe** and mesophile. Grows well on common sugars, a few amino acids and other compounds as sole carbon source. The **major phospholipid fatty acids (PFLAs) are $C_{16:0}$ iso and $C_{18:1}$ ω9*c***, and **MK-7(H_4) is the predominant menaquinone** in the only species that has been tested. Some species are sensitive to desiccation.

DNA G+C content (mol%): 71–72 (Lc).

Type species: **Solirubrobacter pauli** Singleton, Furlong, Peacock, White, Coleman and Whitman 2003, 489^{VP}.

Further descriptive information

This genus is represented by two species, each one represented by a single strain, and the description must necessarily be preliminary. Clones of 16S rRNA genes with high sequence similarity to members of this genus are frequently encountered in clone libraries of agricultural, pasture and forest soils; insect guts; plant-associated bacteria; and aerosols (Brodie et al., 2007; Fall et al., 2007; Gremion et al., 2003; Joseph et al., 2003; Singleton et al., 2003; Wang et al., 2008; Youssef et al., 2009; Yu et al., 2008). Presumably, this genus is representative of a group of abundant but largely uncharacterized microorganisms.

For the type strain of *Solirubrobacter pauli* B33D1^T, cells are short rods, especially in older cultures (Singleton et al., 2003). Much longer cells are occasionally observed in fresh cultures. In liquid culture, cells often grow in long chains that wrap around each other producing large aggregates (Figure 426). Even in rich medium, only a low cellular density (maximum turbidity, near 0.1 at 600 nm) is obtained. Colonies are usually pink in color. Plates incubated at higher temperatures (≥28°C) often produce less pigment initially, although a deep pink color appears over time. The color resembles that of *Rubrobacter* species, and the pigments like those of *Rubrobacter* species are not easily extracted using traditional methods. However, methanol can extract a small amount of pigment, which has absorption maxima at 466, 493, and 526 nm. These maxima are similar to those reported for pigments extracted from *Rubrobacter radiotolerans* (Saito et al., 1994).

The menaquinone composition has only been examined in *Solirubrobacter soli*, where it was found to be MK-7(H_4) (Kim et al., 2007). The major phospholipid fatty acids (PFLAs) are $C_{16:0}$ iso and $C_{18:1}$ ω9*c*. Smaller amounts of $C_{18:3}$ ω6*c*, $C_{17:1}$ ω6*c*, $C_{19:0}$, $C_{18:0}$ iso, and $C_{16:0}$ may also be present. Related organisms *Conexibacter woesei*, *Patulibacter minatonensis*, and *Patulibacter americanus* also

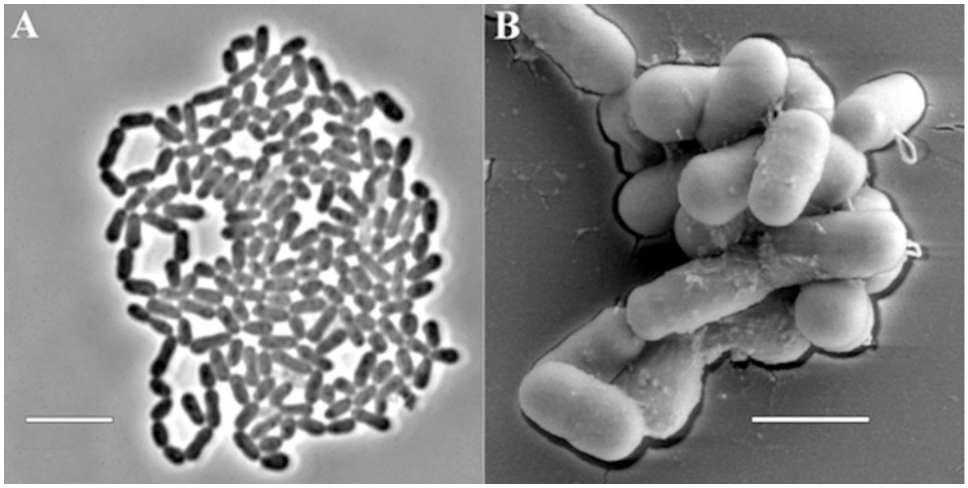

FIGURE 426. Morphology of *Solirubrobacter pauli*. Photomicrographs of strain B33D1 grown in nutrient broth. (A) Phase-contrast image of an aggregate of cells. Scale bar = 5 µm. (B) Scanning electron micrograph of an aggregate. Scale bar = 1 µm. (Reprinted with permission from Singleton et al., 2003. Int. J. Syst. Evol. Microbiol. *53*: 485–490.)

possess high levels of $C_{18:1}$ ω9*c* (Monciardini et al., 2003; Reddy and Garcia-Pichel, 2009; Takahashi et al., 2006).

Enrichment and isolation procedures

The type strain B33D1^T of *Solirubrobacter pauli* was isolated from a burrow of the epigeic earthworm *Lumbricus rubellus* in an agricultural soil in Athens, GA, USA (Furlong et al., 2002). Fresh soil was diluted to extinction and plated on medium composed of 50% Nutrient Broth (Difco, pH 7.0, ~23°C). Isolates were allowed to grow for 2 weeks before colonies were picked. A single pink colony was selected and maintained on the same medium. It was the only representative of this taxon of the more than 200 isolates screened from these soils. At present, no evidence suggests that its isolation from an earthworm burrow has significance. Subsequent studies indicated that spread plates greatly underestimate the viability of strain B33D1, and that pour plates containing 1.5% agar enhance plating efficiency.

The type strain Gsoil 355^T of *Solirubrobacter soli* was isolated from soil of a ginseng field in Daejon, Korea (Kim et al., 2007). Soil suspensions were serially diluted and plated on R2A medium (Difco). After 5 d of incubation at 30°C, colorless colonies were transferred to fresh medium.

Maintenance procedures

The organism has been stored at −70°C in medium containing 15% glycerol.

Taxonomic comments

Upon its isolation, *Solirubrobacter* was affiliated with the 16S rRNA group 2 of the *Rubrobacteridae* subclass of the *Actinobacteria* phylum, as defined by Holmes et al. (2000). Aside from the thermophilic and radiation-resistant species of *Rubrobacter*, group 2 at that time was based entirely on gene sequences obtained directly from soil DNA. Concurrent with the description of *Solirubrobacter*, another mesophile *Conexibacter woesei* isolated from soil and the moderate thermophiles *Thermoleophilum album* and *Thermoleophilum minutum* were also recognized as members of group 2 (Monciardini et al., 2003; Yakimov et al., 2003). Although originally described in the 1980s, the relatedness of *Thermoleophilum* to the *Actinobacteria* was not known until sequencing of its 16S rRNA genes. Subsequently, additional related genera and species were isolated from soil, including *Patulibacter minatonensis*, *Patulibacter americanus*, and *Solirubrobacter soli* (Kim et al., 2007; Reddy and Garcia-Pichel, 2009; Takahashi et al., 2006).

Based upon the low degree of sequence similarity of their 16S rRNA genes and phenotypic differences, the genera *Thermoleophilum*, *Solirubrobacter*, *Conexibacter*, and *Patulibacter* were classified in separate families (Stackebrandt, 2004; Takahashi et al., 2006; Zhi et al., 2009). In recognition of the differences between *Thermoleophilum* and other members of the group, the families were subsequently classified into two orders, *Thermoleophilales* and *Solirubrobacterales* (Reddy and Garcia-Pichel, 2009). More recently, phylogenetic analyses of the 16S rRNA genes failed to provide strong support for the relatedness of these groups to *Rubrobacter* (Ludwig et al., 2012). For that reason, they are currently classified within the class *Thermoleophilia*. Although represented by only a few cultivated bacteria, the large number of genes cloned from mesophilic soils suggests that these are abundant and diverse groups in nature. However, it is very speculative to infer the properties of the uncultivated members at this time.

Differentiation of species of the genus

The descriptions of *Solirubrobacter pauli* and *Solirubrobacter soli* were based upon descriptions of single strains with growth properties measured under somewhat different growth conditions. Therefore, the reliability of the reported differences in phenotype is not certain. With that caveat, *Solirubrobacter pauli* but not *Solirubrobacter soli* utilizes acetate, D-sorbitol, and L-alanine as sole carbon sources. *Solirubrobacter soli* but not *Solirubrobacter pauli* grows in 1% (w/v) NaCl.

List of species in the genus *Solirubrobacter*

1. **Solirubrobacter pauli** Singleton, Furlong, Peacock, White, Coleman and Whitman 2003, 489[VP]

pau'li. N.L. gen. n. *pauli* of *Paulus*; named for the prominent soil microbiologist Eldor Alvin Paul.

Cells are rods (ca. 1.4 µm × 0.7 µm). Much longer cells are occasionally observed in fresh cultures, and older cultures generally have uniformly shorter rods. In liquid culture, cells often grow in long chains that wrap around each other to produce large aggregates. A capsule is not present. Colonies grown on Difco Nutrient Broth agar plates are round, convex, with entire edges, and usually pink in color. Catalase-positive and oxidase-negative. Casein and Tween 80 are not hydrolyzed. No hemolysis is observed on blood agar. In minimal medium, a variety of sugars serve as sole carbon sources including fructose, galactose, glucose, lactose, mannose, sorbitol, sucrose, and xylose. Cellobiose and mannitol do not support growth. Among the organic acids, pyruvate supports good growth. Acetate supports weak growth. Citrate, malate, and succinate do not support growth. Casamino acids provide good growth. When tested individually, only the amino acids alanine, arginine, and lysine support growth. Glycerol is the only alcohol tested that supports growth. Alcohols that do not support growth are methanol, ethanol, 1-propanol, 2-propanol, butanol, isobutyl alcohol, and iso-amyl alcohol. Of the aromatic compounds tested, only chlorogenic acid supports growth. Anthranilic acid, benzoic acid, catechol, protocatechuic acid, *p*-coumaric acid, gentisic acid, ferulic acid, *p*-hydroxybenzoic acid, syringic acid, and vanillic acid do not produce observable growth after 2 weeks. Ammonium will serve as a sole nitrogen source, and Casamino acids will serve as a sole carbon and nitrogen source. Nitrate and urea are not nitrogen sources. Optimal growth at 28–30°C and pH 6.0–6.5. The temperature and pH ranges for growth are 19–38°C and 6–7.5. It fails to grow anaerobically and requires at least 1% (v/v) air for growth. No growth is observed in the presence of 1% NaCl. Sensitive to polymyxin, ampicillin, tetracycline, and streptomycin.

DNA G+C content (mol%): 71.8 (Lc).

Type strain: B33D1, ATCC BAA-492, DSM 14954, JCM 13025.

Sequence accession no. (16S rRNA gene): AY039806.

2. **Solirubrobacter soli** Kim, Na, Lee, Im, Soung and Yang 2007, 1454[VP]

so'li. L. neut. gen. n. *soli* of the soil, the source of the type strain.

Cells are short rods, 1–3 µm in length. Colonies are not pigmented following growth at 30°C on R2A agar. Weakly positive for oxidase. Gelatin is hydrolyzed. Sugars serve as sole carbon sources, including L-arabinose, L-fucose, D-glucose, D-maltose, D-melibiose, L-rhamnose, D-ribose, sucrose, and glycogen. Other utilized compounds include adipate, gluconate, *myo*-inositol, L-proline, *N*-acetyl-D-glucosamine, and salicin. Compounds that do not support growth as sole carbon source include 2-ketogluconate, 3-hydroxybenzoate, 4-hydroxybenzoate, 3-hydroxybutyrate, 5-ketogluconate, acetate, caprate, citrate, itaconate, lactate, L-malate, malonate, phenylacetate, propionate, suberate, *N*-valerate, D-mannitol, D-sorbitol, L-alanine, and L-histidine. In the API test systems, the following reactions were positive: *N*-acetyl-β-glucosaminidase, acid phosphatase, alkaline phosphatase, cystine arylamidase, esterase (C4), esterase (C8), α-glucosidase, β-glucosidase, β-galactosidase, leucine arylamidase, and valine arylamidase. Nitrate is not reduced to nitrite or N_2. Optimal growth at 30°C, slow growth at 15°C, and no growth at 37°C. Growth is observed in 0–1.5% (w/v) NaCl.

DNA G+C content (mol%): 71.5 (Lc).

Type strain: Gsoil 355, JCM 14923, KCTC 12628, LMG 23485.

Sequence accession no. (16S rRNA gene): AB245334.

Co.ne.xi.bac.te.ra.ce′a.e. N.L. masc. n. *Conexibacter* type genus of the family; suff. -*aceae* ending to denote a family; N.L. fem. pl. n. *Conexibacteraceae* the *Conexibacter* family.

The pattern of 16S rRNA gene sequence signatures consists of nucleotides at positions: 144:178 (U–A), 145:177 (U–A), 293:304 (G–C), 377:386 (C–G), 408:434 (A–U), 418:425 (U–A), 590:649 (U–A), and 600:638 (U–G) (Zhi et al., 2009). The family *Conexibacteraceae* is a member of the order *Solirubrobacterales* Reddy and Garcia-Pichel (2009).

Type genus: **Conexibacter** Monciardini, Cavaletti, Schumann, Rohde and Donadio 2003, 574^{VP}.

Taxonomic comments

The family *Conexibacteraceae* Stackebrandt 2005 contains the genus *Conexibacter* Monciardini et al., 2003 and belongs, together with the families *Solirubrobacteraceae* Stackebrandt 2005 emend. Zhi, Li and Stackebrandt 2009 and *Patulibacteraceae* Takahashi, Matsumoto, Morisaki and Ōmura 2006 emend. Zhi, Li and Stackebrandt 2009, to the order *Solirubrobacterales* Reddy and Garcia-Pichel 2009 (Reddy and Garcia-Pichel, 2009; Stackebrandt, 2004; Takahashi et al., 2006; Zhi et al., 2009). The members of the order *Solirubrobacterales* represent a separate cluster in the phylogenetic tree (http://www.arb-silva.de/projects/living-tree/) and are coherent with respect to the set of 16S rRNA gene signature nucleotides, the positive Gram-staining, the occurrence of *meso*-diaminopimelic acid in the peptidoglycan and seven isoprenoid units in the side chain of the respiratory quinones as well as to the psychrotolerant to mesophilic growth (Reddy and Garcia-Pichel, 2009). The affiliation of the family *Conexibacteraceae* to the order *Rubrobacterales* Rainey et al. 1997 emend. Zhi, Li and Stackebrandt 2009 as proposed by Stackebrandt et al. (1997) and Zhi et al. (2009) is neither supported by the topology of the phylogenetic tree (http://www.arb-silva.de/projects/living-tree/) nor by phenotypic characteristics. The families *Conexibacteraceae*, *Rubrobacteraceae*, *Solirubrobacteraceae*, *Thermoleophilaceae*, and *Patulibacteraceae* contain only few culturable strains and the family *Conexibacteraceae* is based on a single strain only. However, many 16S rRNA gene sequences of clones from soils of different regions of the world (e.g. Rheims et al., 1996; Rheims and Stackebrandt, 1999; Yakimov et al., 2003) and of unidentified soil isolates (Joseph et al., 2003; Sangwan et al., 2005) show high similarities to cultured organisms of this group (see Figure 427). It is expected that additional strains will be isolated after elaboration of appropriate cultivation techniques, which will give a better insight into the phenotypic diversity of members of the orders *Rubrobacterales*, *Thermoleophilales*, and *Solirubrobacterales*.

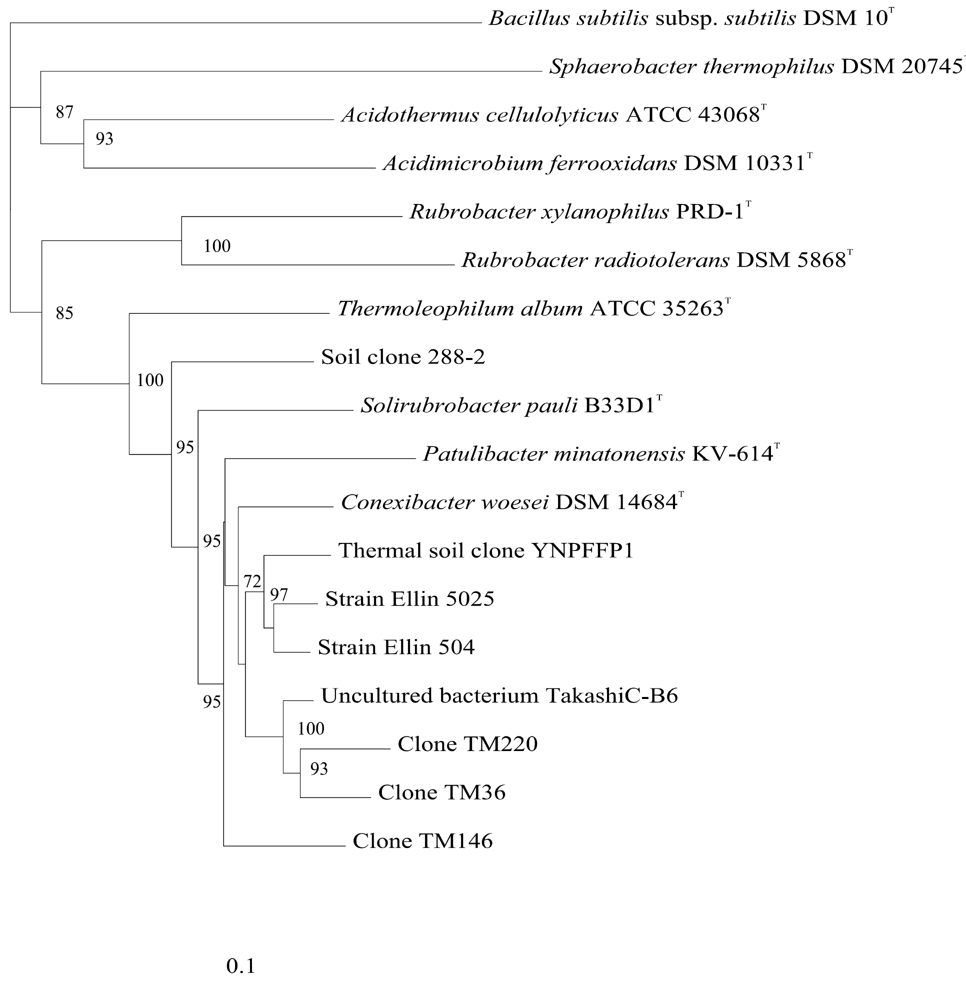

FIGURE 427. 16S rRNA gene sequence neighbor-joining tree (Felsenstein, 1993) of *Conexibacter woesei* DSM 14684^T among representatives of the class *Rubrobacteria*, including species with validly published names, unidentified strains, and clones obtained from environmental DNA. Bootstrap values (>70%) of 1000 resamplings (Felsenstein, 1985) are indicated at nodes. *Bacillus subtilis* subsp. *subtilis* DSM 10^T served as root. Bar = 10 nt substitution per 100 nt.

Genus I. **Conexibacter** Monciardini, Cavaletti, Schumann, Rohde and Donadio 2003, 574^{VP}

Peter Schumann

Co.nex.i.bac′ter. L. part. adj. *conexus* bound, tied; N.L. masc. n. *bacter* rod; N.L. masc. n. *Conexibacter* a rod that is bound.

Cells are small rods (0.6–0.7 × 0.9–1.2 µm), occurring singly or in pairs. **Gram-stain-positive** and **non-sporulating**. **Motile by long, peritrichous flagella.** Aerobic. **Catalase- and oxidase-positive**. The **peptidoglycan** is of the **A1γ type** (based on ***meso*-diaminopimelic acid**, direct cross-linkage). Mycolic acids are absent. The major isoprenoid quinone is menaquinone **MK-7(H_4)**. The **polar lipid** pattern consists of **phosphatidylinositol** and an unidentified phospholipid; amino-functional lipids and glycolipids are absent. The **fatty acid profile** is dominated by **oleic, 14-methyl-pentadecanoic, hexadecanoic, and ω6*c*-heptadecenoic acids**. Phylogenetically, the genus is a member of the family *Conexibacteraceae* Stackebrandt 2005 emend. Zhi, Li and Stackebrandt 2009, order *Solirubrobacterales* Reddy and Garcia-Pichel 2009.

DNA G+C content (mol%): 71 (HPLC).

Type species: **Conexibacter woesei** Monciardini, Cavaletti, Schumann, Rohde and Donadio 2003, 574^{VP}.

Further descriptive information

The genus *Conexibacter* was established to accommodate an isolate from forest soil that showed only remote 16S rRNA gene sequence similarity to validly named taxa (Monciardini et al.,

2003). *Conexibacter woesei* shows the 16S rRNA signature nucleotide A at position 906, but displays U instead of A or C at position 955, a substitution that is typical of members of the sublasses *Rubrobacteridae* and *Sphaerobacteridae* (Reddy and Garcia-Pichel, 2009; Stackebrandt et al., 1997).

An insertion of approximately 100 nt within domain III of the 23S rRNA genes found in members of the subclass *Actinobacteridae* but absent in *Atopobium minutum* (Embley and Stackebrandt, 1994) was also not detected in *Conexibacter woesei* strain ID131577^T, suggesting that the deep-branching lineages of the class *Actinobacteria* might differ in this feature from members of the subclass *Actinobacteridae* (Monciardini et al., 2003).

The closest phylogenetic neighbors of *Conexibacter woesei* ID131577^T with validly published names are *Solirubrobacter soli* Gsoil 355^T (Kim et al., 2007), *Patulibacter americanus* (Reddy and Garcia-Pichel, 2009), *Patulibacter minatonensis* JCM 12834^T (Takahashi et al., 2006) and *Solirubrobacter pauli* ATCC BAA-492^T (Singleton et al., 2003) with 94.3, 93.5, 93.5, and 93.3% 16S rRNA gene sequence similarities, respectively (according to a search using the EzTaxon server; Chun et al., 2007). Only moderate 16S rRNA gene sequence similarity values are shown between *Conexibacter woesei* ID131577^T and strains of other members of the subclass *Rubrobacteridae* Rainey et al. 1997 emend. Stackebrandt 2004 (Stackebrandt, 2004; Stackebrandt et al., 1997) (see Figure 427), e.g. 90.2 and 90.1% similarity, respectively, with *Thermoleophilum minutum* and *Thermoleophilum album* (Zarilla and Perry, 1984, 1986), and 84.5% with *Rubrobacter xylanophilus* (Carreto et al., 1996). The 16S rRNA gene sequences of the isolate and its phylogenetic neighbors *Solirubrobacter soli*, *Solirubrobacter pauli, Patulibacter americanus*, and *Patulibacter minatonensis* fell into a cluster consisting of clones of hitherto-uncultured bacteria obviously occurring worldwide in different soils (Rheims et al., 1996; Rheims and Stackebrandt, 1999; Yakimov et al., 2003) and strains of the subclass *Rubrobacteridae* isolated from pasture soil (Ellinbank, Victoria, Australia) by cultivation on modified VL55 medium (Sait et al., 2002) and incubation at 25°C for up to 3 months (Joseph et al., 2003; Sangwan et al., 2005). The highest binary similarity value (95.8%) was found between *Conexibacter woesei* ID131577^T and strain Ellin 504 (Sangwan et al., 2005).

The isolation and cultivation of representatives of this phylogenetic cluster offered the opportunity to gain an insight into the phenotypic characteristics of these organisms. Colonies of strain ID131577^T are smooth, mucoid, and of whitish-creamy color on Todd–Hewitt agar. They are sticky and difficult to disintegrate. Cells of *Conexibacter woesei* ID131577^T are short, Gram-stain-positive rods (0.6–0.7 × 0.9–1.2 µm), occurring singly or in pairs. Cells are motile by long peritrichous flagella (Figure 428). After approximately 1 week of cultivation in liquid media, rigid nonmotile spiral bodies are observed by phase-contrast microscopy (shown by Monciardini et al., 2003). Electron microscopic investigation revealed that these bodies were formed by self-aggregation of flagella (Figure 428) in a way that cells may become entangled in flagellar networks (Figure 428). Discarded flagella give rise to the formation of undulating or spiral bodies with a regular periodicity of approximately 2–3 µm (Figure 428). This aggregation of cells via a flagellar network appears to be a unique feature of *Conexibacter woesei*.

Strain ID131577^T shows peptidoglycan of type A1γ based on directly cross-linked *meso*-diaminopimelic acid, whereas mycolic acids are absent. A unique feature of strain ID131577^T is the occurrence of the tetrahydrogenated menaquinone MK-7(H_4), which has not been found as a single respiratory quinone in other bacteria before. Phosphatidylinositol and an additional unknown phospholipid are components of the polar lipid pattern, but not amino-functional lipids or glycolipids. The fatty acid profile of strain ID131577^T is composed of $C_{18:1}$ ω9*c* (41.4%), $C_{16:0}$ iso (16.3%), $C_{17:1}$ ω6*c* (13.9%), $C_{16:0}$ (12.7%), $C_{16:1}$ ω7*c* (1.9%), $C_{18:0}$ (1.6%), $C_{17:1}$ ω8*c* (1.5%), $C_{19:1}$ ω6*c* (1.5%) and $C_{17:0}$ iso (1.2%) (fatty acids representing less than 1% of the total fatty acids are not reported). The DNA G+C content of the type strain of *Conexibacter woesei* is 71 mol%.

Strain ID131577^T grows on brain-heart infusion (BHI; Difco), trypticase soy-yeast extract medium (medium no. 92, www.dsmz.de), and Todd–Hewitt agar at 28–37°C and pH 7–7.5 under aerobic conditions. No growth occurs under anaerobic conditions or at NaCl concentrations higher than 2% (w/v). Physiological features and susceptibility to antibiotics are given in the species description.

Isolation and maintenance procedures

Strain ID131577^T was detected as a contaminant during the isolation of filamentous actinomycetes from a soil sample of a wooded area in Gerenzano, Italy. Soil was plated on half-strength HV medium (Hayakawa and Nonomura, 1987) following dilution in water. Colonies were serially transferred on new half-strength HV medium, ISP3 medium (Shirling and Gottlieb, 1966), and Todd–Hewitt medium (Difco) until pure colonies were obtained.

Serial transfers at 4-week intervals followed by maintenance at 4°C and storage of cells as 20% (w/v) glycerol suspensions at −20°C and at −80°C were suitable provisions for preservation. Long-term preservation methods are freeze-drying in skim milk and maintenance in liquid nitrogen at −196°C.

Differentiation of the genus *Conexibacter* from related genera

Signature nucleotides that differentiate the genus *Conexibacter* from members of the families *Patulibacteraceae* and *Solirubrobacteraceae* are the following: 52:359 (U–A), 144:178 (U–A), 408:434 (A–U) and 999:1041 (G–U) (Reddy and Garcia-Pichel, 2009). The genus *Conexibacter* can be differentiated from other culturable members of the classes *Thermoleophilia* and *Rubrobacteridae* by 16S rRNA gene sequence similarity values of <95%. The phenotypic characteristics of *Conexibacter woesei* ID131577^T and its closest phylogenetic relatives *Solirubrobacter pauli* B33D1^T, *Solirubrobacter soli* Gsoil 355^T, *Patulibacter americanus* CP177-2^T and *Patulibacter minatonensis* KV-614^T are compiled for comparison in Table 320.

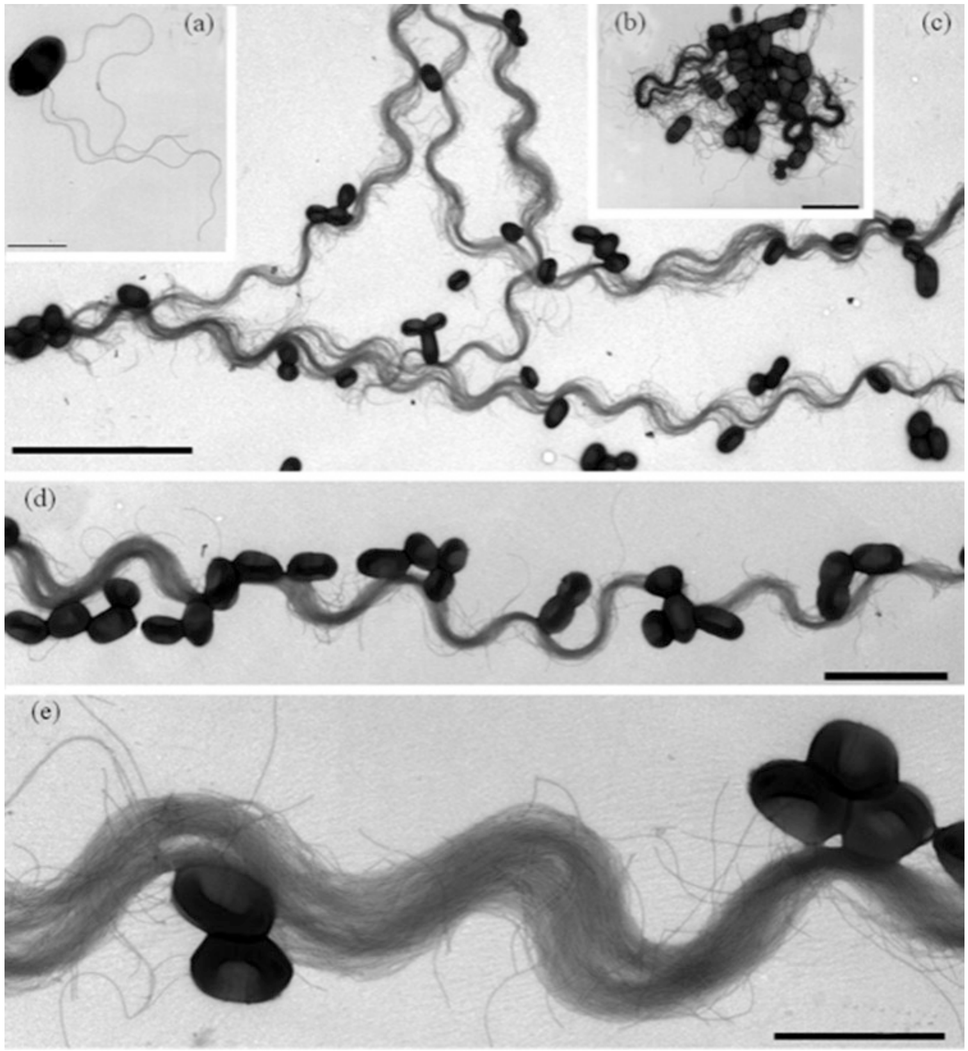

FIGURE 428. Electron micrographs of negatively stained cells of strain ID131577^{T}. Individual bacteria exhibit peritrichous long flagella (a). After a longer period of growth, bacteria form aggregates (b) and, due to self-aggregation of flagella, they exhibit an undulating network-like structure with entangled bacteria (c–e). Bars: (a, e), 1 μm; (b, d), 3 μm; (c) 5 μm. (Reprinted with permission from Monciardini et al., 2003. Int. J. Syst. Evol. Microbiol. *53*: 569–576.)

List of species of the genus *Conexibacter*

1. **Conexibacter woesei** Monciardini, Cavaletti, Schumann, Rohde and Donadio 2003, 574^{VP}

woe′se.i. N.L. gen. masc. n. *woesei* of Woese, named to honor Carl R. Woese for his pioneering work on the use of 16S rRNA in phylogenetic analysis.

In addition to the properties described for the genus, colonies on Todd–Hewitt agar are smooth, mucoid to sticky, and of white to cream color. Nitrate is reduced to nitrite. Gelatin and esculin are hydrolyzed. Urea is not decomposed. NaCl is not tolerated at concentrations of 2% (w/v) or above. The type strain is able to utilize the following substrates: glycerol, L-arabinose, D-ribose, D-xylose, acetic acid, α-ketovaleric acid, propionic acid, pyruvic acid (Biolog GP microplate), methylpyruvate, β-hydroxybutyric acid, α-ketoglutaric acid, and α-ketovaleric acid (Biolog GN microplate). The type strain shows the following enzyme activities: esterase for 2-naphthyl caprylate and 2-naphthyl butyrate, leucine arylamidase, acid phosphatase, and naphthol-AS-BI-phosphohydrolase (API ZYM test). The following tests of the Biolog substrate panels, API 20NE gallery, and API ZYM enzyme assay are negative: mannan, α-cyclodextrin, dextrin, glycogen, Tween 40, Tween 80, *N*-acetyl-D-galactosamine, *N*-acetyl-D-glucosamine, adonitol, D-arabitol, cellobiose, iso-erythritol, D-fructose, L-fucose, D-galactose, gentiobiose, α-D-glucose, *myo*-inositol, α-lactose, α-D-lactose, lactulose, maltose, D-mannitol, D-mannose, melibiose, methyl β-D-glucoside, raffinose, L-rhamnose, D-sorbitol, sucrose, trehalose, turanose, xylitol, monomethyl succinate, *cis*-aconitic acid, citric acid, formic acid, D-galactonic acid lactone, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, α-hydroxybutyric acid, γ-hydroxybutyric acid, *p*-hydroxyphenylacetic acid, itaconic acid, α-ketobutyric acid, DL-lactic acid, malonic acid, quinic

Family III. **Patulibacteraceae** Takahashi, Matsumoto, Morisaki and Ōmura 2006, 405^VP

Yōko Takahashi

Pa.tu.li.bac.te.ra.ce′a.e. N.L. masc. n. *Patulibacter* type genus of the family; suff. -*aceae* ending to denote a family; N.L. fem. pl. n. *Patulibacteraceae* the *Patulibacter* family.

Cells are rods, Gram-stain-positive, non-endospore-forming. Cell-wall peptidoglycan is based upon *meso*-diaminopimelic acid. The main isoprenoid quinone is demethylmenaquinone. Mycolic acids are absent. The signature nucleotides in the 16S rRNA gene sequence (*Escherichia coli* sequence; Brosius et al., 1978) of members of the family are: 52:359 (C–G), 98 (A), 139 (G), 144:178 (C–G), 370:391 (C–G), 580:761 (U–A), 590:649 (U–A), 600:638 (U–G), 670:736 (A–U), 953:1228 (G–C), 954:1226 (G–C), 999:1041 (U–A), 657:749 (U–A), 681:709 (U–A), 941:1342 (A–U), 1051:1207 (G–C), and 1311:1326 (A–U). Phylogenetically, the family is a member of the phylum *Actinobacteria*, class *Thermoleophilia*, order *Solirubrobacterales*.

DNA G+C content (mol%): 72.0 (HPLC).

Type genus: **Patulibacter** Takahashi, Matsumoto, Morisaki and Ōmura 2006, 405^VP emend. Reddy and Garcia-Pichel 2009, 91.

Further descriptive information

In the present volume, the order *Solirubrobacterales* Reddy and Garcia-Pichel 2009 contains three families, *Conexibacteraceae*, *Solirubrobacteraceae*, and *Patulibacteraceae* (Takahashi et al., 2006). The family *Patulibacteraceae* can be distinguished within the order *Solirubrobacterales* on the basis of 16S rRNA signature nucleotides (Stackebrandt et al., 1997; Reddy and Garcia-Pichel, 2009).

The family *Patulibacteraceae* comprises the sole genus *Patulibacter*.

Genus I. **Patulibacter** Takahashi, Matsumoto, Morisaki and Ōmura 2006, 405^VP emend. Reddy and Garcia-Pichel 2009, 91

Yōko Takahashi

Pa.tu.li.bac′ter. L. adj. *patulus* spreading; N.L. masc. n. *bacter* from Gr. n. *baktron* a rod; N.L. masc. n. *Patulibacter*, spreading growth-bacterium.

Cells are rods, Gram-stain-positive, and non-endospore-forming. Bacterial respiration is aerobic. Cell-wall peptidoglycan contains ***meso*-diaminopimelic acid (DAP)**, alanine, and glutamic acid. Cell-wall type A1γ (based on *meso*-DAP, direct cross-linkage). The acyl type of the peptidoglycan is acetyl. The fatty acid profile is dominated by **$C_{18:1}$ ω9*c***, $C_{15:0}$ anteiso, and $C_{17:0}$ anteiso. Mycolic acids are absent. The predominant isoprenoid quinone is **demethylmenaquinone with seven isoprene units (DMK-7).**

DNA G+C content (mol%): 72.0 (HPLC).

Type species: **Patulibacter minatonensis** Takahashi, Matsumoto, Morisaki and Ōmura 2006, 405^VP.

Further descriptive information

Patulibacter minatonensis forms flat and nearly transparent colonies with a white color on one-fifth strength nutrient agar (1/5 NA, Difco), ISP 3 medium (Shirling and Gottlieb, 1966), and R2A agar (Difco) consisting of 0.05% yeast extract, 0.05% proteose peptone, 0.05% Casamino acids, 0.05% glucose, 0.05% soluble starch, 0.03% sodium pyruvate, 0.03% dipotassium phosphate, 0.005% magnesium sulfate, and 1.5% agar, and with a pale yellow color on heart infusion agar and Todd–Hewitt agar (Difco) consisting of 0.9% beef heart digest, 1.1% pancreatic digest of casein, 0.3% soy bean peptone, 0.2% glucose, 0.25% sodium carbonate, 0.05% monosodium phosphate, 0.2% sodium chloride, and 1.5% agar. Bacterial cells are rod-shaped (1.2–1.5 × 0.6–0.7 μm), Gram-stain-positive, show negative oxidase reaction and reduce nitrate to nitrite. Cells possess motility due to the presence of long flagella (Figure 429). The strain does not grow on media containing ≥2% (w/v) NaCl. The pH range for growth is 6–8. The temperature range and optimum temperature for growth is 16–28°C and 24–27°C, respectively.

Enrichment and isolation procedures

Patulibacter minatonensis KV-614 was isolated from a soil sample using an agar medium supplemented with superoxide dismutase (SOD) following the method of Takahashi et al. (2003). Glucose-peptone-meat extract agar (GPM agar) medium consisting of 1% D-glucose (Wako Pure Chemical Industry), 0.5% peptone (Kyokuto Seiyaku Co.), 0.5% meat extract (Kyokuto), 0.3% NaCl and 1.2% agar (Wako) was used for isolation. Solid GPM agar medium supplemented with SOD (Sigma) was prepared by spreading SOD (300 U/plate) on the surface. Then 100-μl samples of soil suspensions diluted with sterilized water were spread on dishes of these solid media, which were incubated at 27°C for 14 d. The strain was cultured on 1/5 NA, ISP 3 medium, heart infusion agar, R2A agar, Todd–Hewitt agar (Difco), and yeast extract-glucose agar medium containing 1.0% yeast extract (Difco), 1.0% glucose, and 1.2% agar.

The appropriate cultivation conditions have not been found for many unknown micro-organisms. While searching for factors that promote bacterial colony growth, it was found that using isolation agar medium supplemented with SOD increases the number of colonies from a soil sample and that addition of SOD and catalase increases it still further (Takahashi et al., 2003).

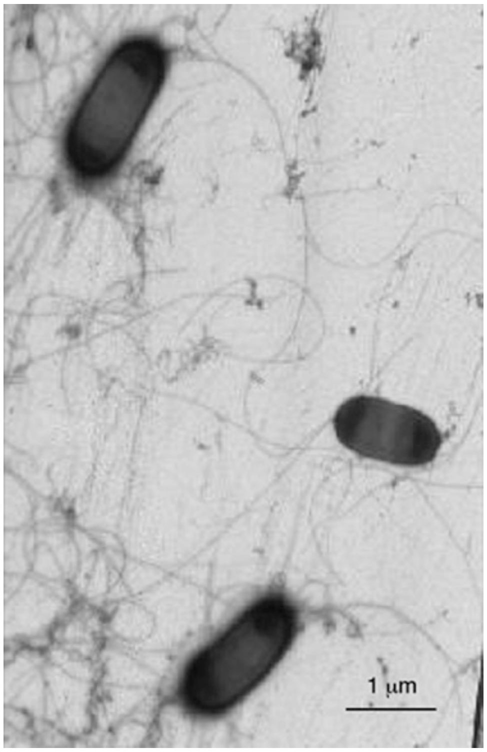

FIGURE 429. Transmission electron micrograph of negatively stained cells with long flagella of *Patulibacter minatonensis* KV-614. (Reprinted with permission from Takahashi et al., 2006. Int. J. Syst. Evol. Microbiol. *56*: 401–406.)

Maintenance procedures

Cultures can be maintained in the laboratory by transfer to the same media used for isolation and stored for a short period. One-fifth strength nutrient agar medium is recommended for maintenance. Recommended conditions for long-term preservation are storage at −80°C with 20% glycerol or lyophilization in the presence of 10% skim milk as stabilizer. The lyophilized ampoules should be stored at 5°C.

Differentiation of the genus *Patulibacter* from other genera

Figure 430 shows a phylogenetic tree constructed by the neighbor-joining method on the basis of 16S rRNA gene sequences of *Patulibacter minatonensis* KV-614 and closely related taxa. *Patulibacter* forms a distinct branch within the order *Rubrobacterales* (Stackebrandt et al., 1997), and is associated with the genera *Conexibacter* (Monciardini et al., 2003) and *Solirubrobacter* (Singleton et al., 2003). The 16S rRNA gene sequence similarity of the type strain KV-614 to *Conexibacter woesei* DSM 14684 is 92.4% and to *Solirubrobacter pauli* B33D1 is 89.7%. The genus *Conexibacter* has one species. The new species of *Solirubrobacter*, *Solirubrobacter soli* Gsoil 355, reported in 2007, also has a low 16S rRNA gene sequence similarity (91.8%) to the type strain (Kim et al., 2007).

Table 320 shows the phenotypic characteristics of *Patulibacter minatonensis* and two related genera, *Conexibacter* and *Solirubrobacter*. *Conexibacter woesei* also contains *meso*-DAP in the cell wall peptidoglycan and produces long flagella, but clearly differs from *Patulibacter minatonensis* in the major menaquinone MK-7(H_4) and predominant fatty acids. *Solirubrobacter pauli* and *Solirubrobacter soli* are also different from *Patulibacter minatonensis* by being non-motile cells and having different fatty acid composition.

Miscellaneous comments

The signature nucleotides in the 16S rRNA gene sequence of members of the subclass *Rubrobacteridae* (Stackebrandt, 2004), which has been elevated to class *Rubrobacteria*, 127:234 (G–C), 291:309 (U–A), 955:1225 (U–A), 1115:1185 (C–G), and 1410:1490 (A–U) (*Escherichia coli* sequence; Brosius et al., 1978) is also present in *Patulibacter*. An A residue at position 906 and a U residue at position 955 are characteristics of members of the class *Rubrobacteridae* (Stackebrandt et al., 1997).

Figure 431 shows a phylogenetic tree constructed with 16S rRNA gene sequences of strain *Patulibacter minatonensis* KV-614 and those of its closest clonal and cultured relatives retrieved from the GenBank database. Clones prefixed "TM" were isolated from a peat bog (Rheims et al., 1999, 1996), and strains prefixed "Ellin" were isolated from Australian soils by culture on simple solid media at 25°C for up to 3 months (Joseph et al., 2003; Sait et al., 2002). The sequences of clones YNPFFP1 and 1959-7 are available from public databases. The closest sequence is that of the bacterium Ellin 5025 (93.2%). This reveals that the strain is closely related to a phylogenetic cluster consisting of uncultured bacteria from terrestrial environments and unidentified bacterial strains.

DMK-7 detected in *Patulibacter minatonensis* KV-614 is a unique isoprenoid quinone and has been known to occur in *Enterococcus faecalis* (Hiraishi, 1988), *Pasteurella*, and *Haemophilus* (Kroppenstedt and Mannheim, 1989). Demethylmenaquinones hitherto have been detected in two genera *Patulibacter* and *Demequina* (Yi et al., 2007) in the class *Actinobacteria*.

Since this chapter was prepared, a second species, *Patulibacter americanus*, was published (Reddy and Garcia-Pichel, 2009); see Table 320 in *Conexibacteraceae*, above, for distinguishing characteristics.

List of species of the genus *Patulibacter*

1. **Patulibacter minatonensis** Takahashi, Matsumoto, Morisaki and Ōmura 2006, 405[VP]

mi.na.to.nen′sis. N.L. masc. adj. *minatonensis* pertaining to Minato-ku, the ward of Tokyo, Japan, where the species originated.

Patulibacter minatonensis forms flat and nearly transparent colonies with whitish or pale yellow color. Cells are 1.2–1.5 × 0.6–0.7 μm in size, motile by long flagella, aerobic, Gram positive, and non-endospore-forming, catalase-positive, and oxidase-negative. Cell-wall peptidoglycan contains *meso*-DAP, alanine, and glutamic acid. The acyl type is acetyl. Mycolic acids are absent. The predominant isoprenoid quinone is DMK-7. Cellular fatty acid components are ω9c octadecenoic acid (oleic acid, $C_{18:1}$ ω9*c*, 63%), 12-methyl tetradecanoic acid ($C_{15:0}$ anteiso, 10%), 14-methyl hexadecanoic acid ($C_{17:0}$ anteiso, 8%), hexadecanoic acid ($C_{16:0}$, 5%), and octadecanoic acid ($C_{18:0}$, 4%). The strain does not grow on media containing 2% (w/v) NaCl. The pH range for growth is 6–8. The temperature range for growth is 16–28°C.

The type strain is able to utilize the following substrates: dextrin, inulin, mannan, *N*-acetyl-D-mannosamine, L-arabinose, D-arabitol, cellobiose, D-fructose, L-fucose, D-galactose, D-galacturonic acid, α-D-glucose, *m*-inositol, maltose, maltotriose, D-mannitol, D-mannose, D-melezitose, α-methyl-D-galactoside, β-methyl-D-glucoside, α-methyl-D-glucoside, α-methyl-D-mannoside, D-psicose, L-rhamnose, salicin, sedoheptulosan, turanose, α-hydroxybutyric acid, lactamide, D-lactic acid methyl ester, L-lactic acid, L-serine, 2,3-butanediol, adenosine, inosine, uridine, adenosine-5′-monophosphate, fructose-6-phosphate, glucose-1-phosphate, glucose-6-phosphate, DL-α-glycerol phosphate, D-ribose, D-tagatose, D-xylose, acetic acid, propionic acid, D-alanine, putrescine, maltose, potassium gluconate, adipic acid, and L-malic acid. The type strain shows the following enzyme activities: alkaline phosphatase, elastase (C4), elastase lipase (C8), lipase (C4), leucine arylamidase, acid phosphatase, and naphthol-AS-BI-phosphohydrolase.

In the disc susceptibility test, cells are susceptible to tetracycline (30 μg/disc), polymyxin B (300 IU/disc), amikacin (30 μg/disc), chloramphenicol (30 μg/disc), erythromycin (15 μg/disc), ciprofloxacin (5 μg/disc), tobramycin (10 μg/disc), vancomycin (30 μg/disc), kanamycin (30 μg/disc), gentamicin (10 μg/disc), ampicillin (10 μg/disc), and imipenem (10 μg/disc). Conversely, cells are resistant to aztreonam (30 μg/disc), ceftazidime (30 μg/disc), nalidixic acid (1 μg/disc), norfloxacin (10 μg/disc), and oxacillin (1 μg/disc).

DNA G+C content (mol%): 72.0 (HPLC).

Type strain: KV-614, NRRL B-24346, JCM 12834, NBRC 100761.

Sequence accession no. (16S rRNA gene): AB193261.
